In the Wake of the Explosion at Nanaimo, B. C., Canada

Brief Survey of Conditions — Carelessness, Indifference or Ignorance of Fireboss Cause of Disaster Rather Than Failure of Lamp

IN THE issue of *Coal Age*, Jan. 25, p. 184, there appeared an interesting article written by Mr. W. H. Moore, Manager, Wakesiah Mine, Western Fuel Corp., Nanaimo, B.C., entitled, "The Relative Safety of Safety Lamps under varying conditions." Mr. Moore gives some details of an explosion in the Wakesiah mine, which caused the loss of two lives, a fireboss and a fellow workman, and states what he believes was the probable cause of the explosion.

According to Mr. Moore's account, the fireboss went into a working place that was idle owing to the presence of a highly explosive mixture. For the purpose of removing the gas, he used a compressed-air jet, under a pressure of 90 lb. per sq.in., which gave the air an estimated velocity at the nozzle, say between 2,000 and 3,500 ft. per min. Mr. Moore seems to think that the cause of the explosion, was this highly explosive mixture coming in contact with the fireboss's safety lamp, which was the standard Wolf type, approved for use in gaseous mines.

Lamp Found in Perfect Condition and Later Withstood Four Severe Tests

This lamp was found, after the explosion to be in perfect condition and properly assembled. The gauzes and glass were undamaged. Later, in the lamproom, the same lamp withstood a severe test, being exposed to an explosive mixture four times in succession without failing. Close examination of the inner gauze, showed signs of intense heat, which was not apparent on the outer gauze.

Thirteen men, including the fireboss, were in the mine at the time of the explosion. Eleven of these men were on the intake side of the air-current, or outby from the point where the explosion occurred, while one was on the return side from that place. The fireboss, who was found in the place, where the explosion occurred and the workman on the return side were both killed; but the other eleven men, working on the intake side, escaped without injury.

Carelessness or Lack of Knowledge Charged

From the description given by Mr. Moore, it is evident that while coal dust may have contributed to the explosion it did not, in my opinion, contribute to the propagation of the explosion, which seems to have traveled with the ventilating current. Assuming that this "highly explosive mixture" was ignited at the Wolf lamp carried by the fireboss, there would seem to have been a certain amount of carelessness, indifference or lack of knowledge on his part.

The practice of blowing out explosive mixtures with compressed air is not to be commended, any more than that of brushing out an accumulation of gas with a piece of brattice cloth or a coat. The fireboss's lamp was found a distance away from where he lay; and I would infer that he must have placed the lamp on the floor where it was exposed to the explosive mixture driven out by the air blast. That the lamp became heated is not at all surprising.

Tests Have Shown Under What Conditions All Types of Lamps Will Pass Flame

The fact that a safety lamp will pass flame when heated is nothing new. Numerous tests made with every type of safety lamp have proved that under certain conditions of velocity, temperature, position of lamp, and with certain percentages of methane and dust, the flame of burning gas within the lamp will pass through the protecting gauze to the outside atmosphere.

If as Mr. Moore states this Wolf lamp gave signs of having been heated to such a point as to pass flame, it must be that the average temperature of the mine was very high, or there was a high percentage of methane traveling in the air-current. An ordinary Davy lamp, that withstood a current velocity of 307 ft. per min., with 4.5 per cent of methane, failed in the same current when a very small amount of coal dust was added.

Not only did the lamp pass flame, in that instance, but it did so without the gauze becoming as hot as would be required were no dust present. Again, a Clanny lamp, found comparatively safe when held in a vertical position, failed easily when tilted sideways, even with a small flame.

Small Lamp Flames Claimed to Be Particularly Dangerous in Gas

In his pamphlet on safety lamps, No. 3, Marsaut states, "It is especially with small flames that the lamps failed." Every mining book we read emphasizes the importance of exercising care in the use of the safety lamp, protecting it against sudden rush of air, high velocities and keeping it in an upright position.

One point seems quite evident; namely, there was no great velocity of air traveling at the working face, or it would have been unnecessary to have used the compressed air to blow out the gas. The fact that this was done while a man was working in the return current from the place, is certainly bad mining practice, and should be prohibited by the rules of the Wakesiah mine as it is by the rules at other mines in British Columbia.

Referring to the four successful tests, made in the lamproom after the lamp was recovered from the mine, Mr. Moore does not state the kind of gaseous mixture used in those tests, or whether the tests were made in a chamber, where the velocity was equal to that to

which the lamp was exposed in the mine. Nor does he say whether coal dust was present in the testing chamber, such as would very likely result in a working place when an air pressure of 90 lb. per sq. in. was turned on, giving a velocity of from 2,000 to 3,500 ft. per min.

Wolf Lamp Held in High Esteem

The Wolf lamp is used extensively both for lighting and testing purposes. It is generally regarded as a most excellent lamp. The lamp has been tested in air currents measuring 3,600 ft. per min. and containing 9 per cent of methane and found safe when properly handled. The lamp may develop weakness when not held in a vertical position, and, in this case, being on the floor, it may have been tilted a considerable angle. It appears to me that, under the conditions described, the lamp does not seem to have failed, as much as the fireboss to whom it was entrusted.

Regarding Mr. Moore's plea for some other and safer means of testing for gas, allow me to point him to the Burrell gas detector, which has given good satisfaction wherever used. In the mines of the Crow's Nest Pass, the Burrell detector is in general use, though it cannot be said to have superseded the Wolf safety lamp for making a rapid determination of the condition of the mine atmosphere. Admittedly, it takes more time to determine the percentage of gas, in the mine atmosphere, with the Burrell device, than with the Wolf safety lamp, but the results in the use of the former, are more accurate and more satisfactory than with the latter.

Improvement in Methods of Testing for Gas Will Insure Increased Safety

Mr. Moore's idea of having the fireboss use a twin-bulb electric head lamp, with switch to extinguish the light while making a test for methane with a Wolf safety lamp having its flame set low to prevent the overheating of the lamp, may not prove as satisfactory as expected, in view of the statement previously quoted from the pamphlet of Mr. Marsaut, claiming a lesser degree of safety in small flames in the lamp.

In common with Mr. Moore, I trust the time is not far distant when we can improve on the present means of detecting methane, and developing methods that will insure a plentiful supply of pure air sufficient to dilute and render harmless inflammable and noxious gases in our mines. In the meantime, we can all find some assistance by following the rules laid down in the Mines Act, which require an adequate amount of pure air that shall be made to sweep the face of every working place.

If this is done it will not be necessary to use compressed air to dislodge explosive mistures, and will at the same time, lessen the dangers surrounding the use of the safety lamp. I would, also, emphasize the idea of more education and less legislation. If this fireboss had received proper instruction in regard to how he must handle his safety lamp, and had followed those instructions, this accident could have been avoided. In our own narrow mining sphere, we have safety blocks that are left open, which makes them a source of danger, instead of being a means of safety. Some time ago we had a "Safety explosive" that turned out to be safe only when used under certain conditions. We have had safety lamps now for many years; but these have only been safe in the hands of capable men who have handled them properly.

Glen Calder.

Fernie, B.C.

Circulation in Safety Lamps

Observation in testing often deceptive—Gas-charged air may appear to enter at top of lamp—Study of conditions shows this is not natural.

REFERRING to the inquiry of Francis Devlin, *Coal Age*, Feb. 8, p. 260, in regard to the question of where air and gas enters the lamp, in making a test for gas in the mine, let me give a little of my own experience with safety lamps, covering a period of 46 years.

During that time I have handled all kinds of safety lamps, both in England and in this country, having worked mostly in mines where lamps were required. For a while I was under the same impression as my friend correspondent in *Coal Age*. Like him, my observations led me to think that the gas-charged air entered the top of the lamp whenever the test was made of a thin layer of gas at the roof.

Experience Often Teaches the Fallacy of Our Wrong Conclusions

For some time this was my full belief, but later experience showed me that such conclusion was wrong. Even assuming that the Wolf or the Koehler is the type of lamp used, as stated by the correspondent, I have no hesitation, now, in saying that the gas and air enter the lamp through the lower portion of the gauze or at the ports of entry below the flame.

To assume that the air and gas enter the top of the lamp and flow downward toward the flame is contrary to a clear understanding of the laws regarding the circulation of air. For that reason, I consider such a proposition as an impossible one, in the ordinary use of a safety lamp in mining practice.

With the editor who has replied briefly to this inquiry, my experience has taught me that the best results are obtained, in testing for gas with a safety lamp, when the circulation within the lamp is wholly ascensional, the air and gas mainly entering the ports of entry below the glass and passing upward and out through the top of the gauze chimney.

If Ports of Entry Are Obstructed Below Some Air May Enter Above the Glass

There are, of course, many conditions and I do not deny that a small portion of the gas or air may enter the lamp through the lower part of the gauze just above the glass, particularly if the lower ports of entry are at all obstructed, a condition that frequently happens in the use of the lamp in the mine.

By way of explanation let me state that in raising a safety lamp to the roof, under a thin layer of gas, it always happens that the gas is more or less disturbed by the movement of the lamp or the person. This causes the gas to mix with the air below and it is fed into the lamp through the regular ports of entry. The action is also assisted by the flow of burnt air outward from the top of the lamp.

In my experience it matters not how slowly you may raise your lamp toward the roof, the thin layer of gas there will be disturbed by the movement of the lamp and the rush of heated air from the top of the chimney. I recall that, on one occasion when testing for small quantities of gas in a certain place I knew was generating gas, my first test was made at the highest point in the place but gave no cap on the lamp. This seemed strange to me, as I had gotten a cap in that place earlier in the day.

After a moment's thought, I blew a gentle whiff against the roof, with the result that a cap at once showed on the lamp. I notice this method of getting a cap from a thin layer of gas at the roof is mentioned by the editor in his reply. He has also explained to my satisfaction the result of the test made by this correspondent, as being due to the rapid diffusion of the gas into the air so diluting the mixture that no gas cap was formed. W. DICKINSON.

Bay City, Mich.

ANOTHER LETTER

NO DOUBT the question asked by Francis Devlin, *Coal Age*, Feb. 8, p. 260, regarding the way gas enters a safety lamp when making a test in the mine, has been asked by more than one fireboss. To tell the truth, it is a matter that set me to thinking many times during the twenty years that I was firebossing in the mines.

It often happened that I had the same experience as that described by Mr. Devlin, when I would find gas in a small cavity in the roof. At such times the test seemed to show that the gas must enter at the top of the lamp. At least, that was my conclusion for a long time.

After thinking the matter over, however, and making a careful study of the laws of gases and air, I have come to the conclusion that my first thought was wrong and the air that reached the flame of the lamp must enter further down where it would not be opposed by the upward rush of the heated air escaping from the top of the chimney.

PRINCIPLE ON WHICH SAFETY LAMPS ARE DESIGNED DEPENDS ON ASCENSIONAL CIRCULATION

One thing in particular that led me to this conclusion was the thought that if the gas did enter the top of the lamp in any quantity, it would become mixed with the products of combustion and change the composition of the mixture so that no cap would be obtained. I have used many kinds of lamps and will say that it makes little difference whether the test is made with a Wolf, Koehler, Mueseler, Marsaut, or the common Davy lamp.

The principle on which all of these lamps are constructed is to provide for a free ascensional circulation within the lamp, in order to secure the most advantageous results, both in the way of illumination and in the observance of the gas cap. Considering the tendency of heated air to rise, there appears to be no reason to think that any amount of air or gas would enter the upper portion of the lamp where it would have to contend against the upward draft caused by the heat of the flame. GEORGE BOWKER.

West Frankfort, Ill.

Inquiries Of General Interest

Dimensions of Mine Ventilation Fan

Estimate Based on Required Volume and Water Gage—Diameter of Fan, Function of Gage and Speed—Width Determined by Air Volume

PLEASE give me the dimensions of a mine fan capable of producing 30,000 cu.ft. of air per minute and show at what speed this fan should be run and the horsepower required to operate the same. What water gage will the fan produce at this speed? What I am anxious to ascertain is the diameter and width of the fan to meet the conditions named.

Hawk Run, Pa. WILLIAM KILPATRICK.

When estimating the dimensions of a mine ventilating fan it is absolutely necessary to know, not only the volume of air required to be delivered, but the water gage or unit pressure (lb. per sq.ft.) against which the fan must operate, as determined by the mine potential or the resisting power of the mine. At the same constant speed, a fan will deliver more or less air, according as the water gage is lessened or increased.

It is important to remember that the unit pressure or water gage, producing circulation in a mine is determined by the resisting power of the mine, which is better expressed as the "mine potential." It is determined by the ratio of the sectional area of the air passage through the mine, to the cube root of the rubbing surface. Or, the cube of the potential is equal to the ratio of the square of the quantity of air in circulation to the unit of ventilating pressure.

The value of this mine potential remains constant for all speeds of the fan. Knowing the mine potential, the unit of ventilating pressure is found by dividing the square of the quantity of air required in circulation by the cube of the potential.

For example, a 6x10-ft. airway, 3,000 ft. long, has a potential of about 483. Then, dividing the square of the circulation by the cube of this potential and that quotient by 5.2, gives for the water gage required to produce 30,000 cu.ft. of air per minute in this airway—

$$w.g. = \frac{30{,}000^2}{5.2 \times 483^3} = 1.53, \text{ say } 1\tfrac{1}{2} \text{ in.}$$

In designing a fan for this circulation, the first step is to determine the peripheral speed, u (ft. per sec.) by means of the formula—

$$u = 47.26\sqrt{w.g.} = 47.26\sqrt{1.5} = 57.88 \text{ ft. per sec.}$$

Or $57.88 \times 60 =$ say 3,473 ft. per min., which is the required peripheral speed to produce a circulation of 30,000 cu.ft. per min., against the given mine potential.

Now, it is possible to choose a fan of lesser diameter running at a higher speed; or to select a fan of greater diameter and run it at a lower speed. Some prefer a high-speed fan, which can be installed at a lower first cost, than a larger fan running at a more moderate speed. The latter, however, allows of a greater margin and permits of a greater increase of speed should the necessity arise for a large increase in air volume owing to any sudden emergency.

In the present case, it is possible to use a 10-ft. fan running at a speed of about 110.5 r.p.m.; or to employ a 6-ft. fan operated at a speed of 184 r.p.m. Either of these fans will yield the required volume of air, under a water gage of 1.5 in.

It is important to observe that as the mine develops, the water gage required to maintain the same circulation will increase in proportion to the increase in

rubbing surface, and the power must be increased in the same proportion. If the power remains constant, however, the increased water gage, due to the development of the mine will be accompanied with a corresponding decrease in the volume of air circulated.

Good mine practice requires maintaining a more or less constant mine potential, by splitting the air so as to increase the area of passage throughout the mine in proportion to the cube root of the increase in rubbing surface. This condition will maintain a practically uniform efficiency in the ventilation of the mine, the power, speed of fan, and volume of air circulated remaining practically constant. In a large development there is, of course, a limit to this condition, as the required air volume will naturally increase with the employment of more men and a larger coal production.

Examination Questions Answered

Examinations Under the Mine Act, Alberta, June, 1922

(Selected Questions)

QUESTION—*A sample of dust from an underground road gives the following analysis: Moisture, 7.87 per cent; volatile matter, 20.30 per cent; fixed carbon, 35.93 per cent; ash, 35.90 per cent; 96 per cent of the dust passing through a 200 mesh. Give your opinion on the relative importance of the constituents and state your conclusions.*

ANSWER—This sample of road dust was probably taken from a road in a bituminous mine. The high percentage of ash shows the admixture of fine shale or stone dust. The comparatively high percentage of moisture shows the effects of dampening the dust to prevent its suspension in the air current. The fine dust of the coal accumulated on the road has lost some of its volatile matter, while the percentage of fixed carbon has been decreased by the admixture of the incombustible shale or stone dust. The fact that 96 per cent of the dust passes through a 200-mesh sieve shows the need of taking extra precaution to prevent a dust explosion.

QUESTION—*Explain fully the first, second and third laws relating to friction of air in mines and give an example by calculation illustrating each law.*

ANSWER—In giving three laws relating to friction of airways, we will first assume a constant size and length of the airway. In that case, the unit pressure or water gage varies as the square of the velocity of the air current. For example, if a pressure of 5.2 lb. per sq.ft., or a 1-in. water gage will produce a velocity of 500 ft. per min., in a given airway, to double this velocity in the same airway will require $2^2 = 4$ times the pressure or water gage.

Again, for the same size or cross-section of an airway, the unit pressure or water gage varies as the length or rubbing surface of the airway. For example, if a given pressure or water gage will produce a certain velocity in a 6x10-ft. airway, 1,000 ft. long, twice that unit pressure or double the water gage will be required to produce the same velocity when the length of the airway has been doubled.

Again, assuming a constant size of airway or a constant cross-section and a constant unit pressure or water gage, the velocity of the air current will vary inversely as the square root of the length or rubbing surface of the airway. For example, if a given pressure will produce a velocity of, say, 300 ft. per min., in an airway of a given cross-section and four miles in length, the same pressure will produce a velocity of $\sqrt{4}$x300, or 600 ft. per min., in an airway of the same cross-section but one mile in length. In that case, the first airway being four times the length of the second airway, the velocity in the second will be $\sqrt{4} = 2$ times that in the first airway, for the same pressure.

QUESTION—*Find the diameter of an upcast shaft necessary to circulate 200,000 cu.ft. of air per minute, with a velocity of 10 ft. per sec.*

ANSWER—A velocity of 10 ft. per sec., is $10 \times 60 =$ 600 ft. per min. The required sectional area of the shaft is, therefore, $200{,}000 \div 600 = 333\frac{1}{3}$ sq.ft. The diameter of this shaft is, therefore, $\sqrt{333\frac{1}{3}} \div 0.7854 = 20.8$ ft.

QUESTION—*If a ventilating fan is running at 100 r.p.m., with 3.75 in. of water gage and its speed is altered so that the gage reads 1.82 in., what will be the speed of the fan?*

ANSWER—It is commonly assumed that the volume of air circulated by a fan varies with its speed, other conditions remaining unchanged. Then, since the unit pressure or water gage varies with the square of the quantity, the gage reading would vary as the square of the speed; or the speed will vary as the square root of the water gage. On this basis, calling the required speed of the fan x, we have—

$$x = 100\sqrt{\frac{1.82}{3.75}} = 69.66, \text{ say } 70 \text{ } r.p.m.$$

In practice, however, this result is not attained; but the fourth power of the speed is found to vary more nearly as the fifth power of the quantity of air in circulation, which makes the speed vary as the eighth root of the fifth power of the water gage; or, in this case,

$$x = 100\sqrt[8]{0.4853^5} = 63.64, \text{ say } 64 \text{ } r.p.m.$$

QUESTION—*If a mine has two openings, one 60 ft. higher in elevation than the other, with the temperature outside at 85 deg., and the temperature inside the mine at 50 deg., will a current of air be produced and, if so, in what direction will it move?*

ANSWER—If it could be assumed that the average temperature of the two shafts differed but slightly from the given temperature of the mine, the solution of the problem would be definite and comparatively simple. We can, however, ignore the two shaft columns below the elevation of the lower opening, and consider an outside air column 60 ft. high and having a temperature of 85 deg., as being in balance with the air column in the upper portion of the deeper shaft, which we will say has a temperature of 50 deg., and is the heavier of these two columns, making that shaft the downcast for the mine, under the assumed conditions. Now, assuming a barometric pressure of 30 in., the weight of the mine air in the shaft column, for a depth of 60 ft., is $60(1.3273 \times 30) \div (460 + 50) = 4.6848$ lb. Likewise, the weight of a 60-ft. outside air column, at a temperature of 85 deg., is $60(1.3273 \times 30) \div (460 + 85) = 4.3836$. The difference in the weights of these two columns represents the unit of ventilating pressure, which is $4.6848 - 4.3836 = 0.3012$ lb. per sq.ft., to a water gage of $0.3012 \div 5.2 =$ say 0.06 in.

Leaders to Study Industrial Co-operation

Leaders in the mining industry will discuss industrial co-operation in various phases at an informal conference April 27 at the Bankers Club in New York City under the auspices of the American Mining Congress, which at its last convention created a special division to develop this subject.

Invitations have been sent to 150 men prominent in mining affairs and acceptances are arriving in sufficient volume to assure success for the conference. In addition, members of the committees on industrial co-operation established by the congress in twenty states will be present. Speakers will include not only mining men but industrial leaders of other lines who have had experience with various plans of co-operation between employers and employees.

Sidney J. Jennings, president of the American Mining Congress, will preside at the conference, which will begin at 12:30 with a luncheon, the discussions continuing throughout the afternoon. W. A. Grieves, national chairman of the Division of Industrial Co-operation of the Mining Congress, will present the objects of the movement and the foundation which has been laid by the division for its work.

John D. Rockefeller, Jr., has been invited to attend and to speak of the co-operative work of the Colorado Fuel & Iron Co., particularly in the results of employees' representation. Among acceptances received are those of S. D. Warriner, C. H. Jenkins, C. F. Richardson, Otis Mouser, A. M. Meguire, J. G. Bradley, Lee Long, Frank Rash, W. H. Cunningham, George Van Dyke, G. D. Kilgore, D. B. Wentz, Albert Nason, Hugh Shirkie and Carl Scholz, representing coal-mining interests.

Governor Cox Attacks Anthracite Tax

Governor Channing H. Cox, of Massachusetts, has written Governor Pinchot, of Pennsylvania, a letter of protest against the Pennsylvania anthracite tax. "In my judgment the policy of your state to use its natural resources to build up Pennsylvania at the expense of less fortunate states is most dangerous," said the Massachusetts executive. "As the nation's non-replaceable natural resources become more completely discovered and developed, such a policy of discrimination would result in economic disaster."

Major Accidents Force Up Fatality Rate In Coal Mines During February

Accidents at coal mines in the United States in February, 1923, according to reports from state mine inspectors to the U. S. Bureau of Mines, resulted in 292 deaths, as compared with 237 in February, 1922. The fatality rate was 5.85 per million tons, based on a production of 49,933,000 tons during the month, as against a rate of 4.96 per million tons during February, 1922, based on an output of 47,742,000 tons. In January, 1923, the fatality rate was 3.23 per million tons produced.

During the first two months of 1923 the number of fatal accidents at coal mines was 487, representing a rate of 4.48 deaths per million tons, based on a production of 108,824,000 tons. In January and February, 1922, fatal accidents numbered 397, indicating a fatality rate of 4.33 per million tons, based on a production of 91,604,000 tons of coal. The figures for 1923 include the loss of 125 lives in two mine explosions; those for 1922 include the loss of 49 lives in four explosions. One of the explosions in 1923 occurred on Feb. 8 at Dawson, N. M., and resulted in the death of 120 men; the other explosion was in Schuylkill County, Pa., on Feb. 21, and killed 5 men.

Comparing the combined record for January and February, 1923, with that for the first two months last year, lower fatality rates per million tons are noted for falls of roof and coal, haulage, explosives, and electricity. An increased rate is noted for gas and dust explosions. The fatality rates per million tons during the first two months of 1922 and 1923, by main causes, were:

	1922	1923
Falls of roof and coal	1.976	1.774
Haulage	.830	.625
Gas and dust explosions	.677	1.305
Explosives	.207	.110
Electricity	.120	.110

5,000 West Kentucky Miners Strike; Would Renew Pact For One Year; Operators Ask Two-Year Renewal

Chicago, April 2.—Approximately five thousand miners struck Saturday night in Christian, Webster and Hopkins counties of western Kentucky. The owners of forty mines there, comprising the Operators' Association—an organization distinct from the West Kentucky Operators' Association—refused to sign with the United Mine Workers of America for a one-year continuance of the present union scale. They held out for a two-year contract and Lonnie Jackson, president of the union district, called out his men. Practically every union mine in the three counties is shut down except those of the St. Bernard Mining Co., which signed on a one-year basis on the 27th at Louisville, when the West Kentucky Operators' Association continued the present contract with the union. A few non-union strip mines in the three counties are unaffected.

On Monday, which was Mitchell day for the United Mine Workers, of course there were no union operations working anywhere, so the evidences of strike in the three counties were few. It was prophesied by both operators and union leaders, however, that the strike would be a peaceful one, at least at the beginning. There is no crying demand for the coal that might be mined in the shut-down properties and no effort is to be made now to run them. The operators say they are well fixed for an enforced idleness.

"We do not want to go open shop," says a statement from Virgil Y. Moore, attorney for the Operators' Association, "but this fight has been forced upon us by union leaders, and if we find it necessary to go open shop in order to have a steady run of our mines, we will do so."

The conference in Madisonville the 27th followed the Louisville meeting at which operators of the West Kentucky Operators' Association, including about two-thirds of the field, had signed up for a one-year continuance of the agreement. The temper of the two meetings was markedly different. At Louisville sweet peace had prevailed and Lonnie Jackson, union district president, had issued a statement saying that probably never again would there be a district strike of miners in western Kentucky.

But at Madisonville the Operators' Association, covering Webster, Hopkins and Christian counties and employing about 5,000 men, refused to sign as the bigger association had done. It declared for a two-year agreement. The union would accept nothing but a contract like that signed with the rest of the field, to run one year. Negotiations soon halted. Both sides left and gave evidences of preparing for a strike.

President Jackson in his union statement said the union was ready to sign for the same period as the rest of the unionized bituminous fields of the country—for the one year recommended by the United States Coal Commission. He said the operators' only reason for insisting upon two years was that a two-year plan would overlap the rest of the country next April 1 and would guarantee that their mines could run after that date no matter what happened elsewhere. He said that if the Operators' Association mine owners did not sign by midnight of March 31, a strike would be called and the mines would shut down in the three counties.

The Operators' Association statement said:

A system has been established in Hopkins and Webster counties during the past four years under the contracts between the operators and the union whereby there could be no controversy between the companies and their employees over any question of wages. Wages were adopted automatically to meet those paid by union operators, our competitors. All grievances were settled by friendly arbitration. No strikes were or could be called on account of controversies in Illinois or other states. Our contracts, being for two years, overlapped all other contracts in other districts. Thus we were able to operate and give our local people work during national strikes. . . . This condition could be continued to our profit and that of our men and communities by the making of a two-year contract, to expire April 1, 1925.

The union, however, refuses to make a two-year contract, insisting on a one-year contract, so that when the usual national strike is called April 1, 1924, our men, though having no grievance or controversy with us, will be arbitrarily called out then.

Rather than have this menace hang over us for a year, we prefer to close down our mines now and let them stay closed until our men can induce their union to restore conditions as they have been for the last four years. . . .

The break lies squarely at the union officials' door; they have refused to make the same contract with us that has for so long worked well to the benefit of all concerned. We shall not attempt to reopen negotiations, as the union district president has assured us that it would be idle to do so. We still are willing to renew the present contract for two years. Economic conditions make it impossible for us to make any other contract. We have no desire to go open shop or non-union unless forced to do so by the union officials.

The area in the affected zone has a yearly output of 4,500,000 tons of coal. About forty plants are included in the Operators' Association, an organization separate and distinct from the West Kentucky Coal Operators Association. Included in the list is the Kentucky Block Coal Corporation, two plants; Hart Coal Corporation, three plants; Reinecke Coal Co., one plant, all near Madisonville; Providence Mining Co., two plants; Diamond Coal Co., two plants; Buckman Coal Co., three plants, all near Providence, Webster County. The remainder are small operations scattered through the three counties.

Twenty-six Companies in Kanawha District Sign New Wage Scale

When it came time, on March 29, to sign a scale covering the year beginning April 1, 1923, for that section of the Kanawha district of West Virginia where mines are operated on a union basis only seventeen producers representing eighteen operations in the entire field signed the new agreement with the United Mine Workers. Companies becoming a party to the scale agreement for the new coal year were: Ivy Branch Coal Co., Spruce River Coal Co., Gilbro Coal Co., Halcon Coal Co., Standard Eagle Coal Co., West Virginia Eagle Coal Co., New Export Coal Co., American Rolling Mills Co., for the Martin mine; Kanawha & Hocking Coal & Coke Co., Blue Creek Coal & Land Co., Fayette-Kanawha Coal Co., Cannelton Coal & Coke Co., Plymouth Coal & Mining Co., Lewis Coal & Coke Co., Crown Hill Coal Co., Coalburg Kanawha Mining Co. and Edwin Marmet Coal Co., for the Monarch and Hernshaw mines.

Although several companies heretofore operating their mines in agreement with the union had not signed any agreement for the new year pending a final decision from the Circuit Court of Appeals on the question of whether they had a right or not to pay over the proceeds of the check-off, 26 companies in the Kanawha field had appended their signatures to a contract with the union on March 31, when the old agreement expired. Companies in addition to those already signed who entered into contract with the union were: Kelley's Creek Colliery Co., Simms Branch Coal Co., Southwestern Splint Fuel Co., Hackett Coal Co., Eureka Coal Co., Big Bottom Coal Co., and the Indian Run Colliery Co. Eighteen companies who had an agreement with the union had not at the expiration of the old agreement signed any new contract with the union.

Although some of the operators not signing have refrained from doing so pending a decision of the court, yet it is understood that others among the 18 will not under any condition again enter into agreement with the union. Some of those not signing have closed down their mines and others are operating now on a non-union basis. As a result of the failure of some companies to sign, radicals have become active on Cabin Creek in the Kanawha field and there have been reports of minor disorders there, though none could be confirmed.

Union mines were closed down on April 2 in observance of Mitchell day.

Since the organization of the field the union has not been given to making concessions to Kanawha operators. In negotiating a wage scale this year, however, the union yielded upon several points, possibly because of the fact that so small a remnant of the operators in the Kanawha field are now operating in agreement with the union. Many

of the amendments to the old agreement, suggested by the operators were adopted.

Included in the list of amendments were a clause eliminating bonuses and premiums formerly paid union miners, except in cases where the sums are paid because of local conditions, a clause providing for tracklaying by the miners and the adoption of a uniform slate scale, superseding local slate-scale agreements.

It is provided in the new agreement that if during the life of such agreement the question of rates for the arc-wall or track-cutting machine arises, the matter will be adjudicated as provided for in Section 25-A of the agreement.

The general rates of pay in the new agreement are the same as those in the old agreement which expired on April 1. Nearly all the mines in the Kanawha field are now operated on a non-union basis.

Full Bench Hears Union Appeal from Judge McClintic's Injunction

Argument of the appeal of the International organization, United Mine Workers of America, from the temporary injunction issued by Federal Judge McClintic at Charleston, W. Va., March 20, forbidding the use of money collected through the check-off for the purpose of unionizing non-union mines, was heard by the full bench of the U. S. Circuit Court of Appeals at Richmond, Va., March 31. William A. Glasgow, Jr., of Philadelphia, represented the union, and S. B. Avis, of Charleston, W. Va.; E. L. Greever, of Tazewell, Va., and A. M. Belcher, of Charleston, appeared for the operators. A decision is expected soon.

Judge Edmund Waddell, Jr., of the appellate court, temporarily suspended Judge McClintic's injunction March 24 and representatives of the miners' union said they would be governed by Judge Waddell's decision pending a final decision by the full court. Meanwhile failure to reach a settlement has been an obstacle to an agreement between operators of union mines and the union for the year beginning April 1.

Slight Gain in German Coal Output in 1922

Complete statistics of German coal production, as well as exports and imports in 1922, now available, are shown in the following tables, accompanied by the figures for 1921 and 1913 for comparison. They comprise the output within Germany's present frontiers, including, however, the alienated parts of Upper Silesia. In the figures of 1922 the latter is omitted starting with June, 1922, when the partition came into force.

OUTPUT OF COAL BY GERMAN MINES
(In Metric Tons)

	1922	1921	1913
Bituminous coal	129,964,597	136,227,231	173,096,426
Brown coal	137,207,125	123,010,036	87,233,084
Coke	29,664,291	27,913,436	32,652,933
Patent fuel — Bituminous coal	5,562,841	5,686,176	6,811,097
Patent fuel — Brown coal	29,466,149	28,243,162	21,976,744

IMPORTS OF COAL BY GERMANY
(In metric tons)

	1922	1913
Bituminous coal	12,598,397	10,540,069
Brown coal	2,015,651	6,987,065
Coke	288,765	594,501
Patent fuel — Bituminous coal	39,241	27,273
Patent fuel — Brown coal	30,557	120,965

The chief countries of origin were Great Britain, Polish Upper Silesia, the Sarre district and, in the case of brown coal, Czechoslovakia. The share of these countries in the total may be seen in the following, in metric tons:

	Bituminous Coal	Brown Coal	Coke	— Patent Fuel — Bituminous Coal	— Patent Fuel — Brown Coal
Great Britain	7,793,888	.....	166,784	20,323	.....
Polish Upper Silesia	2,966,476	.....	88,087	11,760	.....
Sarre District	1,147,000	.....	13,590	2,471	.....
Czechoslovakia	106,286	2,014,351	.....	.....	30,526
Total	12,598,297	2,015,651	288,765	39,241	30,557

Imports of brown coal in 1922 registered a further decline in accordance with the development of German brown-coal mining. Present imports are based upon the higher quality of Czechoslovakian brown coal and upon expediency of transport, which especially applies to Bavaria, which is nearer to the Bohemian fields than to German sources of supply.

GERMAN COAL EXPORTS, EXCLUDING REPARATION COAL:
(In Metric Tons)

	1922	1913
Bituminous coal	5,062,021	34,598,408
Brown coal	14,223	60,345
Coke	908,177	6,432,986
Patent fuel — Bituminous coal	39,474	2,302,602
Patent fuel — Brown coal	418,491	861,135

A large part of these exports was contributed by Upper Silesia, but since the partition of the province these no longer figure as German exports. The remainder consists only of the supply to Holland, which was 1,064,843 tons; to the Sarre district and Switzerland, which amounted to 800,000 tons in the aggregate.

Shipment of reparation coal in 1922 consisted of the following: Bituminous coal, 8,906,503 metric tons; coke, 6,451,862 metric tons; brown coal, 677,127 metric tons. Computed on the efficiency level of bituminous coal at the usual ratio these quantities equal 19,006,248 metric tons. The quantity stipulated for was 21,193,866 tons. The shortage in the deliveries was therefore 2,187,618 tons or 10 per cent.

The Entente countries shared in the reparation deliveries as follows: France and Luxemburg, 13,201,195 tons; Belgium, 3,021,353 tons; Italy, 2,783,700 tons.

Smokeless Coal Output in 1922 Exceeds That of 1921 by 5,000,000 Tons

Of the 33,768,766 tons of smokeless coal produced in West Virginia in 1922, 21,099,725 tons originated on the line of the Norfolk & Western. Smokeless output was more than 5,000,000 tons in excess of that for 1921, it is shown in a table prepared by the Winding Gulf Operators Association. According to that table smokeless tonnage was handled by the various roads as follows for the years 1922 and 1921:

	1922	1921
Norfolk & Western	21,099,725	17,442,900
Virginian	6,402,056	5,674,545
Chesapeake & Ohio	6,266,985	5,601,610
	33,768,766	28,719,055

TONNAGE MOVED BY RAILROADS

Norfolk & Western

	1922	1921	1920

Union Leaders Urge Central Pennsylvania Non-Union Miners to Strike; Operators Report Men at Work

Altoona, Pa., April 2.—Taking advantage of Easter Monday, when practically all the mines in Somerset County were idle, officers of the United Mine Workers held meetings on Monday afternoon in practically every mining town in the county in an effort to get the non-union miners out. Of the 10,000 non-union mine workers in the Windber district, 1,200 have been out on strike since April 1, 1922. The appeal to join the union was made to the remaining 8,800. John Brophy, president of District No. 2, spoke at Windber and other leaders at various places.

All operators having cars report men returning to work, as the men have nothing to gain by joining the union, although the effect of the call will not be known for some time. The strike was called primarily to force a recognition of the union and to collect the check-off. There is no question of wages or working conditions involved. Miners in the Windber area get union rates and work on an eight-hour basis. Operations reached by the Baltimore & Ohio and Western Maryland railroads report no difficulty in mining coal to load all available cars. No attempt has been made to call out miners in other sections of central Pennsylvania and all operators having cars are working as usual. John Brophy, district president of the miners' union, and J. C. Brydon, representing the association of operators, have assured Governor Pinchot that they will use their best efforts to avoid violence. The outcome is being watched with considerable interest, as the Somerset district is the only portion of the central Pennsylvania field still working on a non-union basis. So far, reports indicate, but few men have joined the union ranks.

Governor Pinchot today said that he expected no trouble to come from the strike of bituminous miners in Somerset County, brought about through efforts to unionize the mines. "In view of the coal strike announced to begin today in Somerset County," he said, "I have called in John Brophy, president of District No. 2, representing the miners, and J. C. Brydon, representing the association of operators, and have explained to them both that the state takes no part in the controversy but is interested purely in maintaining public order.

Both Sides Promise to Avoid Violence

"Both Mr. Brophy and Mr. Brydon have given me their assurance that every effort will be made on the part of those whom they represent to maintain order and avoid violence and both have been in communication with their friends in Somerset County in the effort to make this assurance good. I am convinced that there is entire good faith on both sides and I hope for the best results from the effort that each side is making."

If necessary, the state police will be called out, although the Governor intimated that he did not believe the occasion would arise as a result of today's conferences. The state police were in the bituminous field prior to and long after the national guard which a year ago was sent into southwestern Pennsylvania.

It is unofficially reported that the state authorities will allow no outdoor meetings of the miners, but will take no action to prevent those held by the union in halls. The state constabulary are mobilized at points outside but adjacent to the disturbed areas.

For the past three months there has been a great deal of speculation as to whether the local union would attempt to call a strike in Somerset County in a second effort to organize that field. A year ago, on April 1, the union demonstrated unexpected strength in this area and for a time had a large portion of the field on strike. Striking miners were told in the summer of 1922 that the union fields would not settle and return to work until the operators were forced to recognize the union in Somerset County. John Brophy led the fight, backed more by radicals outside his organization than by John Lewis, it appears. He announced not so long ago that radicals in New York City had furnished some $40,000 to help finance his Somerset strike. As the summer wore on the operators were able to augment their forces materially, and, except for one company, to get back to somewhere near normal operation by the time the strike was settled in the union fields in August, 1922.

Not so long after settlement of the big strike was effected, John Lewis called off the strike in the non-union Connellsvill field, adjoining Somerset on the west, where similar efforts to organize the non-union workers directly under the international headquarters had been tried, apparently succeeded at first and then signally failed.

Subsequently Brophy asked Lewis to finance strike benefits for the Somerset strike, which he persisted in continuing. Lewis is reported to have asked him how many men he had out and what chance he had of winning. Brophy, it appears, was optimistic, asserting that 3,000 men were out. After going into the situation Lewis refused to prolong the strike with money from the treasury of the International and Brophy has been forced to go it alone. He tried to raise sympathy in New York City and actually got Mayor Hylan to send a committee to investigate conditions on the theory that the strike in Somerset was endangering the coal supply of public utilities in Greater New York. This investigation provided a junket for some of Hylan's friends and gave some printer a chance to turn out an elaborate brochure, but did Brophy no good.

U. S. D. Corporation May Buy Coal Holdings Of Central Coal & Coke Co.

Negotiations are under way for the purchase by the United States Distributing Corporation of the entire coal holdings of the Central Coal & Coke Co. The Central is understood to be planning to expand its lumber activities.

Harry N. Taylor, president of the distributing corporation and until the first of this year vice president of the Central, says an agreement of sale has been reached with the officers of the Central and now awaits confirmation by the company's Board of Directors. The price agreed upon has not been announced, but in financial circles in Kansas City it is rumored to be in the neighborhood of $10,000,000.

When the deal is closed it is understood the distributing corporation will operate its newly acquired holdings under the name of the Central Coal Corporation, with offices in Kansas City and with few changes in the personnel now employed by the Central Coal & Coke Co.

The property comprises acreage, mines and tipples in Arkansas; Cherokee and Crawford counties, Kansas; eastern Oklahoma; Ray and Macon counties, Missouri, and southern Wyoming, with a distributing organization embracing the southwest district. An official of the Central Coal & Coke Co. says the normal production with present equipment is 17,000 to 18,000 tons a day, with a potential capacity of double that amount. At present rate of production he estimates it would require fifty years to work out the Oklahoma acreage, thirty years for Arkansas, thirty to forty for Missouri and Wyoming, and fifteen for Kansas, but adds that other acreage is available to extend the life of all fields indefinitely. The Central is one of the largest operators in all states of the southwest district, but its greatest production is in Kansas and Arkansas.

Alabama Miners Reject Wage Increase

Union coal miners of Alabama declare that they will not accept the increase in wages announced March 16, but will demand the full scale agreed upon at the conference of bituminous coal producers and miners held in New York City in January. On March 27 they arranged to meet April 3 and present the higher scale.

Governor Smith Abolishes Office of New York Fuel Administrator

Governor Smith of New York issued a proclamation Tuesday night, March 27, abolishing the office of State Fuel Administrator on April 1. The Governor said he had been informed by Major General Goethals, the administrator, that "conditions are so far progressed toward their normal status that after April 1 the allotment basis of coal distribution will terminate and the normal flow of that commodity will be resumed." The offices of all local administrators will close on March 31.

The people of the state should be thankful, the Governor said, that industry and commerce have not been interrupted by the coal shortage. The administrator's offices, the Governor said, will remain open for thirty days after April 1, to conclude all unfinished business.

Under the terms of the New York State Fuel Administrator Law, passed at an extraordinary session of the Legislature last autumn, the Governor is given power to dissolve the administration by proclamation, but no right to revive his powers, so that a future emergency would be necessary in order to revive the measure, and that would have to be done by legislative action.

The administration was in existence nearly seven months. Administration officials said the winding up of its affairs would see New York City well supplied with coal.

Wholesalers to Convene in Cincinnati; Wadleigh Names Advisory Committee

The annual convention of the American Wholesale Coal Association is to be held in Cincinnati. The exact date has not been fixed but it probably will be during the second week of June.

Federal Fuel Distributor Wadleigh announces the appointment of the following advisory committee to co-operate with him in his study of marketing, storage and distribution of coal: T. F. Farrell, Pocahontas Fuel Co.; C. E. Tuttle, Tuttle Coal Corporation; S. L. Yerkes, Grider Coal Sales Agency; George W. Reed, Peabody Coal Co.; W. D. Ord, Empire Coal & Coke Co.; C. E. Bockus, Clinchfield Coal Company; S. A. Scott, New River Coal Company; C. F. Richardson, West Kentucky Coal Corporation; E. M. Poston, New York Coal Co.; S. Pemberton Hutchinson, Westmoreland Coal Co., and E. L. Douglas, First Creek Mining Co. A meeting of the committee is to be called in the near future.

Ford Will Not Mine His New Kentucky Land At Once, but Has Extensive Plans

Ford Motor Co. officials have stated to *Coal Age* that there is no intention of immediately opening up the new Ford coal holdings centering in Clay County, Kentucky. The approximate 120,000 acres of land acquired two weeks ago were bought with the double idea of holding both coal and timber in reserve, they declared. It is recognized that no production worthy of the name can be taken out of the property until a railroad has been projected into the area. No definite railroad building program has been laid down. However, the Detroit, Toledo & Ironton R.R., which is the logical line to extend southward into this new property, will be electrified and supplied with power from the new generating plant at Flatrock, Mich., a few miles west of Detroit, and with purchased power down along the line to the Ohio River, where eventually a hydro-electric plant may be built by the Ford interests. It would then be logical for a steam plant to be built somewhere on the newly acquired coal lands in eastern Kentucky.

It is Mr. Ford's intention to coke all or nearly all of the coal his own plants consume and to encourage the coking of the coal he sells to subsidiary and contributory concerns. It is by no means certain, however, that types of byproduct ovens now standard will be used. Koppers ovens are now in operation at the River Rouge plant in Detroit but Ford engineers are watching with interest the development of new types of ovens which may be used eventually.

In Detroit now the Ford company is producing a little more coke than it consumes and sells it to employees at $8 a ton, which is half the market price in that city. The following table shows a calculated return to the company from a ton of coal if it costs $2.42 per ton at the mine—a figure that may vary:

MATERIALS AND VALUES RECOVERED FROM 1 TON OF COAL AS COKED BY THE FORD MOTOR CO.

1 ton of coal costs, at mine	$2.42
Freight to Detroit, per ton	2.58
Total cost	$5.00
7⅝ gals. of tar, @ 7c. per gal.	= $0.55
2⅛ gals. of light oil, @ 35c. gal.	= 0.81
11,100 cu.ft. of gas produced of which 5,800 cu.ft. is not required for coke-oven operation, @ 30c. per 1,000 cu.ft.	= 1.74
¾ ton of coke, @ $8 per ton	= 6.00
25 lb. ammonium sulphate, @ 3c. per lb.	= 0.75
	$9.85

Battle for Northwest Trade Is On

The Northwest and Midwest are just now reading a good deal of propaganda on the question: "Should rail rates be altered to give Lake docks a better chance at the Northwest market?" The dock interests have petitioned the Interstate Commerce Commission for an adjustment of rates upward on coal shipped from Indiana and Illinois. Preparatory to the hearing in Minneapolis, Minn., May 2, the dock operators are pointing to the rate disadvantage under which they now labor, which enables southern Illinois coal, for instance, to be laid down in Minneapolis for approximately 50c. a ton under any price the docks can profitably make. They point to their $25,000,000 investment and say that without a freight equalization the docks will have to go out of business.

Operators' defenders in Indiana and Illinois reply that the drop in dock business over recent years has been only in the same proportion that coal production the country over has dropped. They point out that the docks, owned by Eastern interests whose mines have heretofore been guaranteed good summer running time by reason of the Lake trade, have been granted a distinct preference in emergencies such as the rail and mine strikes of last summer. They wonder why docks should get this preference at the expense of the people of the Northwest if Indiana and Illinois can undersell them in their own territory.

The case for an increase in rail rates from Illinois and Indiana to Minnesota, Iowa, Wisconsin and the Dakotas is covered in five complaints. The effort is not to get a reduction of rail, lake and rail rates from the Appalachian region northwesterly through the docks but an increase in the all-rail rates from the Western competing mining fields. The dock operators believe the Holmes and Hollowell scale, which now applies to shipments off the docks, should be applied also to coal from Midwestern mines. Illinois men say this would advance Illinois rates from 50c. to $1.40 a ton and would set up a Northwest monopoly for the docks.

N. C. A. Takes Larger Quarters

The National Coal Association, forced by its increasing activities to have more office room, has leased space in the Southern Building, at Washington. For several years the association has occupied an entire floor in the Commercial Bank Building. At various times it has been necessary to make temporary use of space on other floors in this building and in a nearby building. So as to avoid the difficulties arising from a separation of activities, it was found necessary to move the offices to the Southern Building.

The Southern Building is at the corner of 15th and H Streets, northwest. It faces the Shoreham Hotel and is in the very heart of the capital's business district.

A portion of the newly acquired space is being occupied by the statistical force. The remainder of the offices will be moved as circumstances permit, during the next month or six weeks.

Fred W. Lukens, of Kansas City, has been made a member of the Bituminous Operators' Special Committee.

Coal Commission Completes Field Work on Wholesale And Retail Distribution; Sanitary Survey Begun

By Paul Wooton
Washington Correspondent of *Coal Age*

Criticism in the press of the action of the Federal Fuel Distributor in urging early purchase of coal led Commissioner George Otis Smith, of the President's Coal Commission, to state at the press conference on March 31 that he stands squarely with Fuel Distributor Wadleigh in the position he has taken. While Dr. Smith did not say so, there is reason to believe that the other members of the commission deem it the wise policy to begin at this time a definite program of coal storage. This applies to bituminous as well as to anthracite and to steam users as well as to domestic users.

Dr. Smith's references were largely to the policy that should govern the domestic user of anthracite. The advantages that come with the early storage of domestic fuel, both to the individual and to the industry, are such, he pointed out, as to offset the possible speculative advantages which might come were reductions in price made later in the season.

No duplication of the work being done by the commission will result from the studies which are being undertaken by the Federal Fuel Distributor and by the Federated American Engineering Societies. This point was emphasized by Commissioner Smith. His reference to the matter was prompted by recent statements that these studies would overlap, with consequent waste of funds and needless meddling. He declared that every precaution is being taken to prevent any duplication of work. The three studies, he said, will be carefully co-ordinated. While some may think that the expenditure of $700,000 in less than a year on surveys of the coal situation cannot be justified, Dr. Smith pointed out that a saving of that amount to the consumers of coal well may result this year, to say nothing of the permanent results that may follow the only thorough and comprehensive analysis of the coal situation ever undertaken in this country.

Dr. Smith Sets Example in Ordering Early

"Dr. Smith mentioned incidentally that he is practicing what he is preaching in that he personally has followed Mr. Wadleigh's advice and has placed his order for his entire requirements of household fuel for next winter."

During the conference with the correspondents Governor Marshall related this experience: When the removal of appendices just was coming into vogue an Indiana doctor operated on a patient but made the necessary incision on the wrong side of the body, a full 8 in. away from the appendix's nearest point. As a result of the malpractice the patient barely escaped death. Governor Marshall, then a young lawyer, was retained to bring legal proceedings against the physician. After a long legal battle he obtained a judgment in favor of his client, but not until after the members of the medical profession in that vicinity, including many physicians of whose great ability there was no doubt, had interposed every possible technicality and even had resorted to violent distortions of truth and common sense.

Governor Marshall drew no moral from his story, but to his hearers the thought occurred that he believes the same situation exists in the ranks of each group within the coal industry. They are ready enough to accuse each other but are loath to admit any shortcoming on the part of their own colleagues.

At the conference Governor Marshall announced the receipt of a letter from Judge Alschuler which indicated definitely that he would not resume his duties with the Coal Commission. Governor Marshall expressed deep regret that the commission is not to have the advantage of Judge Alschuler's assistance. He spoke highly of Judge Alschuler's ability and stated that he is particularly qualified to pass on many of the questions before the commission. Dr. Smith has not given up hope that the commission still will receive some benefit from the study that Judge Alschuler gave to the coal situation, as it is possible that certain problems will be submitted to him for his opinion.

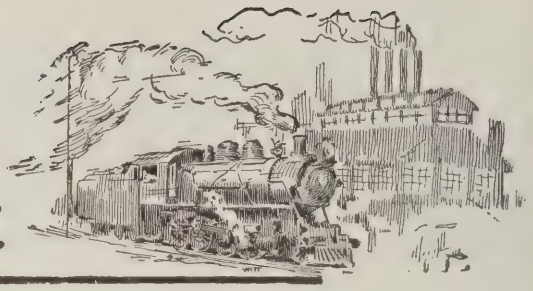
Dr. Smith reported that returns on the cost questionnaires are being received in satisfactory volume and that in many cases companies that had delayed their report had advised the commission that it would be forthcoming at the earliest possible time. In the matter of tabulation the commission's force has been able to keep abreast with the incoming returns. Dr. Smith stated that it had not been necessary to invoke the powers conferred recently by Congress providing for sworn answers to questionnaires.

A published statement to the effect that the commission had sought to induce the Pennsylvania Legislature to defer certain coal legislation was denied by Dr. Smith. He admitted having discussed the matter with Senator Pepper, but, as had been set forth in the commission's letter to J. C. Brydon, of the bituminous operators' special committee, the commission is in no position to memorialize state Legislatures. Dr. Smith reiterated that the commission believes that it would be in the public interest for the Legislatures to withhold legislation until after the commission had completed its study. It obviously would be improper, he said, for the commission to make any such direct representations to a state body.

Personnel Increased 44 in Two Weeks

All field work on wholesale and retail distribution has been completed. As certain phases of the work are concluded the employees engaged in that particular work are dropped from the roll. The augmentation in other branches, however, is requiring additional personnel, with the result that the force grew from 216 to 260 between March 17 and March 31.

Actual work on the sanitary survey, being undertaken at the commission's request by the Public Health Service, is in progress in Belmont County, Ohio, it was stated.



The Coal Commission was very anxious to take advantage of the experience of W. B. Reed in accounting and tax matters, in connection with its study of investments in coal properties. Mr. Reed was forced to decline the tender to direct that study because the Committee on Enrollment and Disbarment of the Treasury Department, to whom the proposition was submitted, ruled that such an appointment in effect would make Mr. Reed a government employee and, therefore, would preclude him from continuing his private practice in matters of taxation before the Commissioner of Internal Revenue.

William Lamont Abbott, chief operating engineer of the Commonwealth Edison Co., Chicago, has been selected to head the special committee of the Federated American Engineering Societies which will make a study of coal storage. Mr. Abbott was born in Whiteside County, Illinois, in 1861. He was graduated from the University of Illinois in 1884. He worked as a machinist and draftsman in Chicago from that date until 1887, when he became president of the National Electric Construction Co. He continued in that position until 1894, when he was made chief engineer of the Chicago Edison Co.'s power house. He served in that capacity until 1899, when he became the chief operating engineer of the company. Mr. Abbott long has been a student of coal storage. He was selected for the chairmanship of the Federated Society's committee on the recommendation of the late Dr. H. H. Stoek, of the University of Illinois.

A digest of the character of state legislation affecting the coal industry proposed and enacted since Jan. 1 is being prepared by the National Coal Association.

Production and the Market

Weekly Review

Prices of soft coal bounced a trifle from the bottom of last week and on Monday upward reactions in three standard grades, eastern Kentucky, Clearfield, and Cambria-Somerset in the East turned the general price average up 6 points in the *Coal Age* Index. On Monday, April 2, the Index stood at 252 as compared with 246 the previous week.

Interest today centers on April prices, as commitments beyond the end of this month are rare, outside of a few pieces of large buyers, largely railroad. Sales for April delivery are at figures around those quoted today, best low-volatiles from central Pennsylvania around $4, from southern West Virginia $3,50@$4, with Illinois screenings holding to $1.90 as a bottom figure.

Except locally no marked changes in the soft-coal market are expected until prices are made for May deliveries.

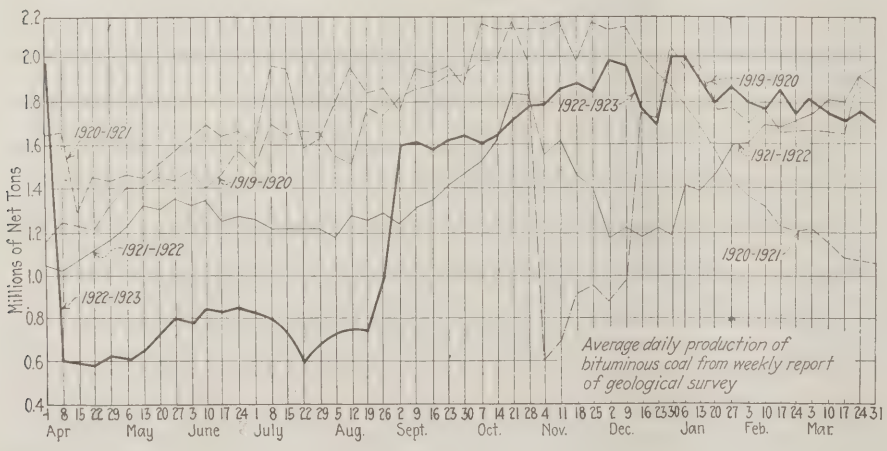
Despite a widespread change for the better in traffic conditions, production decreased, corrected estimates showing less than 10,500,000 net tons of bituminous coal in the week ended March 24.

Export Demand Easy

Export demand continued to sag. Prices eased somewhat and the indications are that European buyers are holding off pending further developments in the Ruhr and further evidence of urgent needs.

The smokeless agencies also have had on hand at Hampton Roads more coal than orders with accumulation, upward of 200,000 tons, mainly low-volatile. At the end of the week Navy standard grades were an easy purchase at $6@$6.25 per gross ton f.o.b. vessel, and now that rehandling congestion at Boston is practically at an end the various New England factors are marking down their current supplies to figures that are little if any above $8.50@$8.75 per gross ton on cars. Much of this coal now being offered was shipped at higher cost and no drastic reduction is expected for another couple of weeks.

Dumpings at Hampton Roads during the week ended March 29 were 370,823 net tons, as compared with 407,234 net tons the previous week, a decrease of 36,411 net tons, and the week past was marked by more than usual dumpings for export at Baltimore.



In the Middle West domestic coals were kept moving, due to weather conditions, but the steam sizes dragged considerably. Eastern Ohio had a dull week and expects nothing unusual to develop until the Lakes are in full swing.

Railroads Consider Contracts

The New York Central R.R. has this week been considering contracts for supplying coal for the new coal year and the trade is awaiting announcement of the range of prices at which this large buyer covered its requirements of several million tons. It generally is conceded in advance that prices are lower than last year. Bids will be opened next week by the New Haven for 250,000 net tons of bituminous coal to be delivered at South Boston, Mass.

"Present estimates of soft-coal production for the week ended March 24," says the Geological Survey, "indicate a total output of 10,443,000 net tons, including coal shipped, mine fuel, local sales, and coal coked. There is thus shown a very slight increase over the revised estimate of 10,428,000 tons for the week preceding and a decrease of approximately one million tons as compared with the output of the corresponding week a year ago.

"Preliminary reports of cars loaded in the week March 26-31 show 41,119 cars on Monday, 31,705 on Tuesday, 29,832 on Wednesday, and 28,059 on Thursday, and for those days totaled 1,000 cars more than for the corresponding period of the week before. Loadings on

Mar. 24 (*a*)	175,000	384,000
Calendar year	1,618,000	4,321,000

(*a*) Subject to revision. (*b*) Revised from last report.

Friday and Saturday, however, will doubtless show much lower production than on the same days of recent weeks and the total output for the week probably will not greatly exceed ten million tons."

As anticipated, the large producers of anthracite made no stir with the opening of the new coal year, reductions of 50c. on buckwheat, rice and barley being the only feature aside from a 15c. cut on pea by two companies. No reductions in the prices of the larger sizes of coal were announced. Reductions in retail prices were announced in Boston, Chicago and Philadelphia. The principal dealers in New York City made no changes in prices.

Retail dealers in hard-coal territory are circularizing their trade urging immediate filing of orders, pointing out that mine prices will show no decline this summer, and suggesting that coal in the cellar prior to Sept. 1, when the wage contract with the hard-coal miners expires, will be good insurance. Independents' prices will slump after the manner of these producers when the edge is off of demand, and thus take from under a portion of the retail trade the argument for an extra dollar or so on householders' prices, but so far there is little evidence of it. Fuel Administrator Wadleigh has issued a proclamation urging early purchase and storage of all kinds of coal that should appeal to the average run of buyer.

Production of beehive coke in the week ended March 24, as estimated by the Geological Survey from reports of cars loaded by the principal coke carriers and in part on reports of producers, was 384,000 net tons as against 410,000 tons in the week preceding. The increase was principally in the output of the Pennsylvania-Ohio region.

Midwest's Burst Is About Over

Cold and more or less raw weather all week throughout the Midwest region kept domestic coals moving out of most fields with no marked drops in price, but steam sizes dragged a good deal and were sold often for whatever they would bring. Nobody is buying heavily, of course. Trading was brisk enough to take up about all the coal hoisted, however, the car supply in most fields was good enough to give oper-

Coal Age Index 252, Week of April 2, 1923. Average spot price for same period $3.07. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the war Industries Board.

ating mines about half time. It is generally admitted that within a few days, when real spring returns, many shutdowns will occur.

Independents in Williamson County are down to $3 on domestic sizes and a low as $2.75 on mine-run. One operator quoted a price of $3 on a contract for lump and egg, about six or seven cars a day for a year. Duquoin field prices are somewhat in line with that of the independents. Jackson County is slightly higher and conditions are somewhat similar to those in Williamson and Franklin County.

The Mt. Olive condition is bad. Steam sizes fail to move and there is little demand for domestic. Steam coal is down to $1.75 for screenings, $2 for nut and slightly above that for steam egg. During the past week Mt. Olive domestic sizes dropped from $4 to $3.50 and it is expected that soon after April 1 a price of $3 will be made.

Business has been good in the Standard field on domestic sizes. Cold weather has forced domestic buying in small quantities and this fell to the cheaper Standard coal. It is understood that coal from around Pinckneyville has been offered on contract for a year, mine run, at less than $2.

Kentucky Market Firmer

As a result of cold weather Western Kentucky felt more demand from retailers during March than normally is the case. General industrial consumption is forcing a slightly better placement of orders on the part of big consumers, while the railroads with heavy tonnage movements are taking a fair amount of fuel. Many wagon and hillside operations have closed down since prices reached present levels, which is making it easier on the larger operations. A threatened strike in one section of the field may have its effect, but the feeling is that the operators will not make an issue of their demand for a two-year instead of a one-year contract.

Northwest Frozen Again

The cold snap did a good deal for the coal trade in the Northwest by way of moving a volume of domestic coal and put off spring navigation by solidifying harbor and shore ice that once had given signs of breaking up. The main interest of Northwest coal men, however, lies not in immediate trade but in prospective freight-rate changes and the future of the docks. Dock propaganda is going out showing that rail rates distinctly favor Illinois and Indiana and that the docks will go out of business if the rate structure is not leveled up at once. Ammunition is piling up for the May 2 hearing in Minneapolis before the Interstate Commerce Commission.

A March survey of the Head-of-the-Lakes docks showed that much less free coal than had been supposed was on hand—about 452,000 tons of bituminous. No price advances were made, however. The continued slump continued instead.

The dock companies are afraid that what coal is carried over will be handled at a loss after the opening of navigation. From present appearances the prices will open up $1 to $1.50 lower than at present.

Milwaukee continues its rather feverish scramble for anthracite, which arrives in small shipments, and for coke, the supply of which is in a constant state of exhaustion. Anthracite screenings are hard to find because so little coal is being prepared.

West Passes Its Cold Peak

The snappy weather of a week ago, which moved all the "no bills" in the Kansas and Oklahoma field and which kept Colorado and Utah coal moving steadily from mines working about 60 per cent of the time, has passed. Once more domestic sizes are a drug in the Southwest while steam demand remains rather steady.

Ohio Trade Shows More Weakness

More weakness has developed in the Ohio coal trade, as a result of smaller orders on the part of steam-coal users and curtailment of business from retail dealers. Little activity is expected before the opening of the lake season, which is likely to begin earlier than at first expected, because of the clearing out of the ice.

Production is jamming the Cincinnati market and the outlet is clogged in all directions. The market for smokeless coal for April opened with a spread in prices that denotes indecision on the part of those who have this coal for sale. Local retail dealers are urging householders to put in their supplies early.

Operators and jobbers in the Cleveland market say that inquiries are few. Contract consumers are hesitant and spot buyers have no difficulty in getting coal. Shipments to the lower Lake ports are growing heavier and early loading tonnage is in good demand. Due to the scarcity of coal at some of the ports, boats are being shifted to fill out cargoes.

Market Dull, Prices Soft, at Pittsburgh

The Pittsburgh market was dull last week, with prices softer. Consumption by industries is heavy and appears to have increased during the past few weeks. Domestic demand practically disappeared several weeks ago. There has been little demand for gas coal for export and scarcely any for steam coal in the past week or two. Some of the small and high-cost mines are now closing and it is believed there probably would have been some closing of mines early in March had it not been for the export demand.

Car distribution in the central Pennsylvania fields, especially along the Pennsylvania R.R., amounted to little more than 20 per cent during the last week in March. There was no increase in demand.

Demand in the Buffalo market is light. Supply is heavy, due to the improved car supply.

Dealers in the Birmingham (Ala.) district are contracting for stocking coal for the new year and a number of mines have already booked orders for such proportion of expected output as they desire to tie up during that period, while others are sold ahead, three, six and nine months. Production is holding up well, being limited only by car supply. A slight labor shortage exists in some sections.

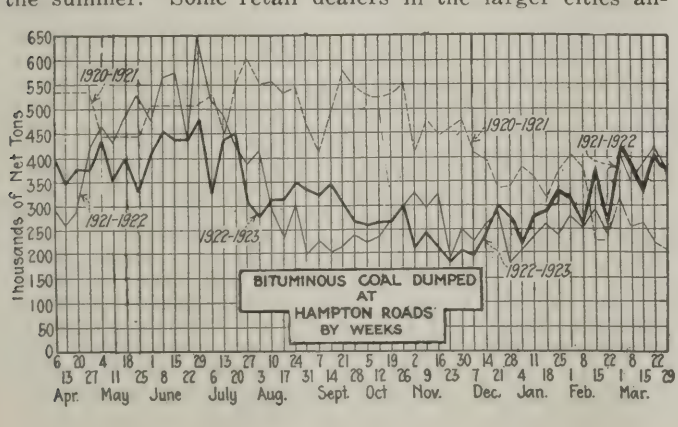
Outlook Unfavorable in New England

There are no bright spots in the current market in New England. Spot coal is easy in all directions, and the outlook for April is not favorable for much improvement. Recent wage advances in the textile industry have given the trade a hopeful view, but the largest of these plants get power from hydro sources and from fuel oil to such an extent that as a whole they are nothing like the factor they were five or six years ago.

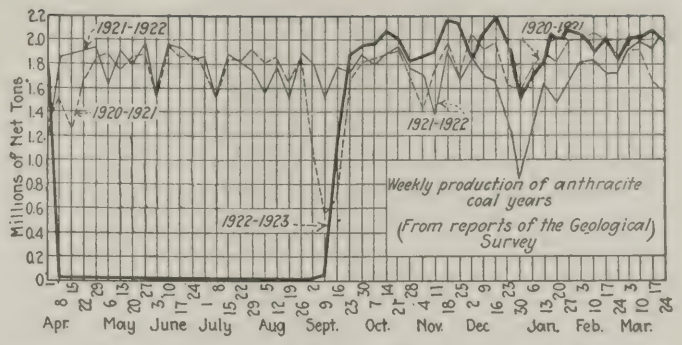
Central Pennsylvania grades all-rail were rather druggy. Quotations were hardly more than nominal, because there is so little buying; there were rumors of extremely low prices, but as a general rule the operators have not yet shown their hand. If some of the non-union operations turn out to be reasonably well supplied with contracts while union mines are idle there will be real cause for trouble.

Contract business in New England appears to be at rather loose ends. At least one or two of the larger operating groups have made new selling arrangements in this territory, and the trade will be interested to see what policies will develop. In practically every instance the contract business that has been closed has been simply a continuation of last year's understanding. In other words, two or three of the Pocahontas and New River agencies have thus far made prices only for April, based on $3.50@$4 per net ton f.o.b. mines, the price depending upon the class of buyer. There is nothing to suggest, however, that there will be any broader market for grades all-rail than was the case last year.

Certain special users of Pennsylvania coals, together with some of the illuminating gas companies, have shown apprehension over transportation difficulties in the way of short car supply and inadequate motive power by continuing to take a proportion of their tonnage via New York and Philadelphia piers. Coastwise rates are reasonably low, especially in railroad-owned transportation, and greater volume is possible under present conditions by rail-and-water as compared with the all-rail route. Congestion is still the rule at certain of the Hudson River gateways, a situation that will take weeks and months to correct.



Demand Slow at New York and Philadelphia



Demand continued slow in both New York and Philadelphia markets, with prices falling slightly. Good coals were scarce for the spot buyer at the New York terminals, it being estimated that from 60 to 75 per cent of the coal at the terminals was on contract.

The Baltimore market was weak. There is small call for coal except in small lots and there is no tendency to stock up. Few contracts are being entered into.

Expect Active Summer Anthracite Demand

Demand for anthracite domestic sizes continued strong throughout March and is expected to be active throughout the summer. Some retail dealers in the larger cities announced a reduction in retail prices while others who had been selling at lower prices for the past several weeks announced no change. Many retail dealers in New York City have sent circular letters to customers advising them to place their orders and are consecutively numbering orders received.

Independent producers have found it necessary to lower their prices slightly but expect that with consumers insisting upon having their coal delivered, demand will increase and that quotations will advance soon.

Dealers in Buffalo are slow to buy independent product, though the quotations have been down to $9. It is not expected that there will be any loading of anthracite at Buffalo for lake shipment until well into April.

"The production of anthracite in the week ended March 24, says the Geological Survey, is estimated, on the basis of 40,648 cars loaded, at 2,126,000 net tons, including mine fuel, local sales, and dredge and washery output. This was an increase of 7 per cent over the preceding week and the record production of the present calendar year.

"Early returns for the first four days of the present week, (March 26-31) show a high rate of production, which, on account of the church holidays, will not be maintained throughout the week and will doubtless fall much below the average for recent weeks."

How the Coal Fields Are Working

Foreign Market And Export News

British Production Reaches Highest for Year; Demand Continues Strong

Production of coal in the British mines hit the highest mark for the year during the week ended March 17 when 5,721,000 tons were produced. The output for the previous week was 5,713,000 tons. The big record for 1922 was recorded during the week of December 16 when 5,742,000 tons were mined.

Pressure on the Welsh market continues heavy, and, though operators have announced that their output till the end of April is sold, they are pressed with urgent demands. The business being received is considerably in excess of available supplies, and this has forced prices to a level which has not been reached since August, 1921, following the resumption of work after the strike of that year. Good business has been done with Germany. France and Italy are much larger buyers of Welsh coal than other countries, and consumers there are unwilling to take American coal as long as Welsh is obtainable. Sellers are not disposed to relax present prices.

Bristol Channel coal exports for the four weeks ended March 9 were 2,316,354 tons.

The demand on the Newcastle market is insistent especially from Germany, in spite of the fact that supplies for early loading are sold out and only occasional loads are available for delivery at any time this side of July. Inquiries extend from April to September delivery, and there is little to sell. These conditions have not been experienced for years.

Export Demand Up at Hampton Roads

Business at Hampton Roads was active last week, and March ended with the heaviest dumping record of the last twelve. Unusually large stocks were on hand, rushed to port by operators on the strength of revived foreign trade, and the result was a weakening of prices which was regarded as wholly temporary.

Export business was on the increase, large cargoes being forwarded to Germany and to Holland, the latter for ultimate consignment to Germany. Coastwise business was somewhat reduced, but bunkers were holding strong. The car situation was reported as from 50 to 60 per cent of normal, whereas hitherto it has been only 30 to 40 per cent of normal.

The outlook was somewhat brighter, due to building up export business, although export inquiries had been reduced. No contracts were in sight as April 1 approached. the tendency of the purchasers being to depend further on spot prices.

Export Shipments from Baltimore

With the filing at the Baltimore (Md.) Custom House of manifests of 16 of the 17 steamers carrying export coal cargoes from that port during March, the total amount of dumpings, including bunkers, is shown to be 109,144 tons for the period from January 1 to March 31, 1923. For the three months there was loaded on ships 7,821 tons more than the total amount of cargoes sent from Baltimore on export during the entire year of 1922. While there was but six vessels to leave Baltimore during January and February with cargoes totaling 13,331 tons and three of these vessels taking 1,472 tons of bunkers, making the total dumpings at tide for the two months 14,803 tons, there were 16 vessels to leave from March 1 to 27 inclusive with cargoes amounting to 91,970 tons, and six of these ships took 2,371 tons of bunkers, making the total dumpings for that period of the month 94,341 tons. Thus far in 1923 there have been 22 vessels to leave here with 105,301 tons of cargo coal, 9 of these ships taking 3,841 tons of bunkers.

During 1922 36 vessels left Baltimore with cargoes amounting to 101,325 tons, 14 of these vessels taking bunkers totaling 6,410 tons, making the total dumpings at tide during last year 107,733 tons.

A summary of the export cargoes for the first 27 days of March is as follows: Porto Rico, 2 ships, 1,028 tons; Holland, 1 ship, 9,625; Italy, 6 ships, 42,138 tons; Germany, 3 ships, 19,119 tons; Peru, 1 ship, 3,348 tons; France, 3 ships, 16,712 tons. Of the above named vessels three ships for Italy took a total of 1,379 tons of bunker coal; 1 ship for Germany took 250 tons of bunkers and 2 ships for France took 760 tons of bunkers, making a total of 2,371 tons of fuel taken by vessels engaged in this trade from Baltimore.

The first shipment of coal to France in many years has been consigned at Hampton Roads aboard the steamer Rothley, which is due to arrive early in April, and to be followed by other steamers in the same trade. An estimated shipment of 1,000,000 tons to France will be made, according to shippers.

News Items From Field and Trade

ALABAMA

Charles F. DeBardeleben, formerly vice-president and general manager of the **Alabama Fuel & Iron Co., was elected to the presidency of the corporation** at a recent meeting of the stockholders, succeeding the late J. M. Overton, who met death in an automobile accident a short while back. Henry Colton, of Nashville, was elected first vice-president to succeed Mr. DeBardeleben. Other executives of the company were re-elected.

ALASKA

Alaska's 1922 coal production totaled 84,403 tons, according to figures made public on March 27. Of that amount 53,658 tons came from the Matanuska field, 26,891 tons from the Nenana field, and the remainder from the Broad Pass, Bering River and Cook Inlet mines. The output in 1922 exceeded that of 1921 by 8,118 tons.

COLORADO

The Midwest Mine., of the Midwest Coal Co., Palisades, located in Mesa County, on the D. & R. G. W. R.R., which closed in June, 1920, was reopened in March, 1922.

Moore No. 2 Mine, of the North Park Coal Co., Ft. Callins, located in Jackson County, on the C. W. & E. R.R., a new mine, was opened in September, 1922.

Rainbow Mine, of the Wyoming & Utah Coal Co., Cheyenne, Wyo., located in Routt County, on the D. & S. L. R.R., which closed in January, 1922, was reopened in August, 1922.

Yampa Mine, of the Yampa Collieries Co., Denver, located in Routt County, on the D. & S. L. R.R., which closed in February, 1922, was reopened in September, 1922.

Postal Mine, of the Postal Coal Mining Co., Denver, located in Routt County, on the D. & S. L. R.R., which closed in February, 1922, was reopened in August, 1922.

The Curtis Mine, of the Colorado Fuel Co., located in Routt County, on the D. & S. L. R.R., which closed in October, 1920, was reopened in August, 1922.

Colorado coal mines produced a total of 1,909,118 tons in January and February, according to a recent report of State Coal Mine Inspector James Dalrymple.

ILLINOIS

The new Henderson mine at Gillespie, Ill., has been connected with the Chicago & Northwestern R.R. by switch track and the **first coal was shipped** to Chicago about March 10.

The Rex Coal Mining Co. has located a vein of coal 4 ft. 8 in. thick on a 600-acre tract of land one-half mile east of Sarner.

The Yankee Branch Coal Co., Georgetown, Vermilion County, has opened a new mine on the C. & E. I. R.R.

The Justice Coal Co., Danville, Vermilion County, has opened a new mine on the Wabash R.R.

The Clover Leaf Coal Co. has reopened its mine at Coffeen, Montgomery County, on the T., S. L. & W. R.R., which was closed in March, 1921.

The Norris Coal Co., Norris, Fulton County, in November, 1922, reopened its mine on the C. B. & Q. R.R., which was closed in the autumn of 1920.

Among the many **Illinois mines that have closed down are these:** Royal mine of the Columbia Colliery Co., at Freeburg; No. 52 mine of the Springfield District Coal Mining Co., near Springfield; the Cantrall mine of the Buckley Coal Mining Co., at Cantrall, and the Empire No. 2 mine of the Illinois Coal Corporation, at Auburn.

On the morning of March 16 a part of the **mine operated by the Security Coal & Mining Co.,** Duquoin, **was flooded** by water following heavy rains. The water did not reach the working faces at any place, and the company is running all its pumps night and day, and expect to be able to operate in about 15 days.

Anton Fanke has resigned as superintendent with the Star Coal Co., Freeburg, and has assumed a similar post with the Little Muddy Coal Co., Tamaroa.

The following **mines in district No. 9 are completely closed down:** Alladin Coal & Mining Co., No. 1, at Cutler; Southern Gem, No. 8, Jamestown; Illinois Sixth Vein Coal Co., Pinckneyville; Kanawha Fuel Co., St. Johns; Willis Coal & Mining Co., No. 1, Willisville; Ft. Dearborn Coal Co., De Soto; Jewell Coal Co., No. 2, Duquoin. The Jewell Coal Co. is planning extensive repairs for its mine.

The Industry Coal Co. organized under the laws of Illinois for the purpose of acquiring approximately 6,200 acres of coal lands in Franklin County, together with two mines, has placed on the market $2,000,000 first mortgage 7 per cent serial gold bonds. John F. Gilchrist, vice-president of the Commonwealth Edison Co., is president of the company. Stuyvesant Peabody, president of the Peabody Coal Co., is vice-president; Edward J. Doyle, vice-president of the Commonwealth Edison Co., secretary, and C. E. Schrage, vice-president of the Peabody Coal Co., treasurer. Directors are Messrs. Gilchrist, Peabody, Doyle, Britton I. Budd, president of the Public Service Co. of Northern Illinois; J. H. Gulick, vice-president of the Commonwealth Edison Co.; C. J. Gray, vice-president of the Peabody Coal Co., and Joseph Solari, secretary of the Peabody Coal Co. Under an operating agreement which extends for the life of the bonds, the Peabody Coal Co., of Chicago, will be in complete charge of the operation of the properties of the new company.

Secretary John Watt, of the Springfield sub-district appealed March 27 to the international executive board of the United Mine Workers **to oust President Frank Farrington,** recently re-elected, and to order a new state-wide election.

The Southern Gem Coal Corporation is sinking a new shaft at its No. 11 mine, near Percy. It will be used for ventilation purposes temporarily after it reaches the coal, but later will be converted into the main hoisting shaft of the mine.

INDIANA

Surveyors have arrived in Petersburg to lay out another seven-mile switch to be built from the Big Four R.R. to the coal fields in Pike County. The new switch will leave the main line at Rogers station just south of the White River crossing and run southeast through the town of Alford, two miles east of Petersburg, and will join the Big Four again at Clark's station, three miles south of Petersburg. The switch will penetrate the 15,000 acres of coal territory recently leased by Pennsylvania coal men, on which testing has been under way for the last two months.

The Globe Coal Co., of Petersburg, **has purchased 22 acres of land south of Rogers** and will move its stripping machines onto the land early this spring. The coal company has donated a new right of way for the Petersburg and Washington highway so that the new bridge over White River can be approached straight and not at right angles.

An explosion in the Wabash mine in Vigo County late in March probably due to ignition of a pocket of gas, resulted in serious injuries to two men, John Armstrong, of West Terre Haute, and Abraham Gallez, of Marion Heights. Both were burned badly about the head and face and upper portions of the body, but it was said the injuries would not prove fatal to either. The mine was not damaged by the explosion and the fire was confined to the immediate vicinity of the blast.

Richard Eddleman and Bert Fredericks, shotfirers, were killed in the mine of the **Carlisle Coal Co.** at Carlisle, by **an explosion in the mine occurring March 19,** and the interior of the mine was badly damaged. Four other men who were on the bottom of the mine at the time of the disaster were brought to the top by the night shift uninjured. The first knowledge of the explosion was obtained when the night shaft reached the bottom and found twisted trackage and trolley wires barring the entries. A mine rescue car was immediately rushed to the scene while the day and night shifts began searching for the entombed men.

The Ogle Coal Co., Indianapolis, has decreased its capital from $150,000 to $100,000.

KENTUCKY

The Payne Pond Creek Coal Co., McAndrews, Pike County, has opened a new mine located on the N. & W. R.R.

The J. E. Polly Coal Co., Millard, Pike County, has opened a new mine at that place on the C. & O. R.R.

The Excelsior Elkhorn Bi-Product Coal Co., Shelbiana, Pike County, has opened a new mine on the C. & O. R.R.

The Looney Justice Coal Co., Regina, Pike County, has opened a new mine, the Looney Justice, on the C. & O. R.R.

The Victor Coal Co., McAndrews, Pike County, has opened a new mine, the Victor, on the N. & W. R.R.

In a preliminary report Lawson Blenkinsopp, Chief Inspector of Mines, states that **in 1922 the total production of Kentucky mines was 41,293,933 tons,** as compared with 30,282,695 tons in 1921, an increase of 11,016,274 tons. The number of mines increased from 641 in 1921 to 719 in 1922. The total number of employees, inside and outside, in 1922 was 57,666, an increase of 7,876 over the previous year, but despite this the fatal accidents were 122, or four less than in the previous year. The average number of days worked was 126, as compared with 109 in 1921. The 418 wagon mines in the state had an output of 414,000 tons. In addition, 64 mines not co-operating with the State Department of Mines had an estimated output of 100,000 tons.

A news item in *Coal Age* March 22 stated that "according to a press statement the State Tax Commission has been busy trying to explain how come that Henry Ford paid $15,000,000 for 30,000 acres of land and improvements in Pike County, when Pike's entire 423,782 acres is assessed at only $19,466,686." Grant Phillips, assistant mine inspector, Eighth district, Pikeville, writes that he thinks this is an error as the stamps on the deed would indicate that only $6,000,000 was paid for the land in Kentucky. Mr. Phillips says he understands that most of the land involved is in West Virginia so that if $15,000,000 was paid $9,000,000 was for property in the latter state. The 1923 assessment for Pike County, Mr. Phillips says, is approximately $27,000,000, the exact figures not being available.

Coal produced in Kentucky in 1922, according to Grant Phillips assistant mine inspector, 8th district, Pikeville, **totaled 41,377,217 tons,** an increase of 11,094,522 tons over 1921. The mines employed 10,712 men outside and 47,607 inside, a total of 58,319. Mines co-operating with the State Department of Mines number 740; there are 98 mines that do not co-operate with the department and 441 wagon mines in the state.

The Elkhorn Coal Co. reports gross earnings for 1922 of $3,443,877 against $2,195,158 in 1921. After payment of all expenses and charges and allowances for taxes, there was a net loss of $99,906 against $380,990 in the previous year. After preferred dividends, there was a deficit of $495,858 and the profit and loss surplus on Dec. 31, 1922, was $495,331 against $909,640 at the end of 1921.

Officials of Perry County have filed a suit in the Franklin County Circuit Court at Frankfort to compel the State Tax Commission to accept assessments of $13,606,753 for 1923 taxation purposes in Perry County. **The commission has ordered an increase of $5,600,000, most of which would be paid by coal interests** in Perry County. The additional assessment is declared unfair and unreasonable.

The Columbus Mining Co., of Chicago, with holdings in eastern Kentucky, has opened a district sales office at 610 Fayette Bank Building, Lexington, John W. Hall, who for the past two and a half years has been associated with the C. L. Ryley Coal Co., has been appointed Southern sales manager.

Congressman **Alben W. Barkley,** of Paducah, who is a **Democratic candidate for nomination for governor, is panning the coal interests** and arguing for a tonnage tax on coal production. He is stirring up much talk concerning coal taxation. In a recent talk he held that the mouth-of-the-mine value of coal production in Kentucky last year was $162,000,000, or more than the present assessed coal-land valuation of the state. "Barkley might as well argue the value of made bricks as against value of clay in a pit," remarked one coal man.

The Louisville coal trade arranged a banquet at the Louisville Old Inn Hotel on April 2 for Morris M. Kling, of the Louisville Coal & Coke Co., who is leaving Louisville in April to make his home at Oakland, Cal.

The Marian Coal Co., Lexington, has recently filed amended articles increasing its capital stock from $200,000 to $400,000.

MARYLAND

The Equitable Fuel Co., of the Maryland Trust Company Building, Baltimore, has increased its capital to $10,000.

The Consolidation Coal Co. had its heaviest production on March 13 for any one day since the miners' strike was declared nearly a year ago. **The day's output was 1,790 tons** from mines Nos. 1, 3, 4, 7, 9, 10, 11 and 13, at Frostburg. It is reported that more than 500 men are now working for the company.

MINNESOTA

A committee from the St. Paul Association has been named to study the use of North Dakota lignite for industrial and other use. The move was made at the instance of representatives of the Association of Commerce, of Minot, N. D., which is seeking to expand the field for lignite.

The Northwestern regional board of the American Railway Association has solemnly passed resolutions urging the coal using public to buy its coal for next season early so that the docks may stock accordingly. It has been remarked in the Twin Cities that this board might as well pass resolutions recommending that spring be inaugurated each year on March 10 or that the ice go out and navigation on the Great Lakes be regularly opened up not later than April 2. The dear public will buy its coal when, as and if it pleases.

E. S. Kendrick, of the Kendrick Coal & Dock Co., Minneapolis, **predicts that the dock coal traffic, once 10,000,000 tons a season, will drop to insignificant amounts** if there is not a speedy revision of the lake and rail rates on coal to equal the favorable rates from the all-rail fields. In reply, a representative of one of the railroads sets up that the rates complained of are generally made by the commission, and could not be changed without resulting in a general change. Yet the all-rail rates were established by carriers of their own volition.

The purchase of coal fields in Kentucky by Henry Ford is expected to forecast the bringing of coal via the Mississippi River to the proposed St. Paul Ford plant.

A good demand for shipments from the docks has resulted at Duluth-Superior harbor through the starting up of some of the mines of the Mesaba iron range. This coal was purchased some time ago.

J. A. Ferguson, manager of the Pittsburgh Coal Co. at Duluth, and **L. D. McNamara**, manager of the Carnegie Coal & Dock Co. at Superior, Wis., **take a pessimistic view of the rate condition to the Northwest.** Both assert that unless a readjustment is accomplished, a minimum amount of coal will be shipped to the docks here this year.

MISSOURI

The Mitchell & Lovell Coal Co. has purchased all of the property of the Hanks Coal Co. from Bevan & Sneed and has obtained a lease from Mrs. Lowry for a considerable acreage of coal land. Immediate arrangements will be made to put this much talked-of coal mine in operation at once. The Mitchell & Lovell company has one mine in operation now.

The Mosby Coal Mining Co. has announced that on April 1 it will begin sinking a new shaft on its property at Mosby and this will result in two mines being put in operation. It has been announced that a large contract from a North Kansas City manufacturing concern will be available as soon as coal is mined. It also is said that if sufficient fuel can be produced a large manufacturing concern will make Mosby its headquarters and will erect a factory here.

The Domestic Fuel Co., of Kansas, has been incorporated with a capital of $500,000 at Mindenmines, to produce and sell coal. Incorporators: G. K. Mackie, J. W. Mackie, A. H. Schlanger, Thomas Mackie, C. M. Sweeney.

NEW YORK

Colonel C. D. R. Stowits, after nine years of close application as **receiver of the bankrupt coal operating firm of Frank Williams & Co., has made a final report**, by which the creditors receive 50c. on the dollar. Judge Hazel highly commended the work on receiving the report. The company owned coal mines, included the Upper Hillville and Oak Ridge, in Clarion County, Pa. Frank Williams, a Buffalo coal shipper of large business capacity, died quite a long time ago. His successors bought the mines, but were unable to operate them profitably.

Timothy Burns, general manager of the Lackawanna plant of the **Bethlehem Steel Co.**, at Buffalo, announces that **two batteries of modern coke ovens** with 60 ovens each and total capacity of 110,000 tons of coke a month, **will be built at once.**

The Anthracite Mining Co. has been incorporated at Albany to open undeveloped coal property in the vicinity of Scranton, Pa. It is affiliated with the Marquette Coal Co. of Albany, and will have headquarters with the Marquette company, which deals in coal at wholesale. The officers of the Anthracite Mining Co. are: President, Arthur T. Palmer; vice-president, Ernest A. Barvoets; vice-president, Lewis F. Harder, Philmont; vice-president and general manager, William B. Vernoy; treasurer, Jacob H. Herzog; secretary, Arthur L. Andrews.

Bids for furnishing 45,000 tons of slack coal to the city waterworks of Buffalo, which is the principal item of that sort in the spring, **were all thrown out** by the City Council on the request of Councilman Kreinheder, who declared that he could buy in the open market lower than the lowest bid (McVicker Coal & Coke Co., Cleveland, $2.25 on a $2.39 freight rate). Shippers say it can be bought for 40c. less, but the high bidding is attributed to the belief that prices will soon advance.

OHIO

Plans are being made by the **Cincinnati Southern to extend that line into the Harlan coal fields,** which will give another outlet to a large tonnage toward the Cincinnati gateway. Word comes from the Louisville and Nashville that it will tunnel through the mountains at Krypton, Ky., to give an outlet to North Fork coal and a part of the acreage recently acquired by Henry Ford from the Peabody interests.

Plans have been submitted to the U. S. Engineer's office in Cincinnati **for the erection of a half million dollar coal-handling plant** to be installed at the foot of Freeman avenue on the river bank. Much mystery surrounds the undertaking but it is a well established fact that this is to be put in by the Island Creek Coal Co. interests. The plans call for the erection of a 70-ft. crane that will swing the coal from the river barges clear to land or to the cars that may be waiting to be filled for rail-river coal. While a great amount of this coal will go to use in Cincinnati and the surrounding territory, in advantageous seasons it will also be shipped to nearby territory where the combined rates apply.

The federal government and especially the Department of the Interior has been called upon **to aid in extinguishing the fire which has been raging in mines around Straitsville and Shawnee in Perry County for the past 40 years.** Representative Randolph, of Perry County, introduced a resolution in the Ohio Legislature asking federal aid. His resolution requests the U. S. Bureau of Mines to co-operate with the Ohio Mining Department in an effort to stop the destruction of coal deposits.

G. M. Richards, general manager of the Cumberland Manchester Ry., a coal line that feeds in to the Louisville & Nashville in southeastern Kentucky, was in Cincinnati recently making purchases. He stated that **many improvements are to be made to the physical properties of this road.**

PENNSYLVANIA

Representative John E. Stavitski, of Luzerne, has introduced a bill which requires that all anthracite knocked from the miners' cars en route from the mines to the breaker shall be weighed and the companies made to pay for it at the prevailing rates, the money to go into a miners' reserve fund for the benefit of injured and aged employees of the said mine. "The miners lose thousands of dollars through the dockage resulting from coal knocked from the cars. It's the miner's coal; they should be paid for it," Stavitski said in introducing his bill.

State Senator C. M. Barr, Allegheny County, has introduced in the Senate **a bill providing for the appointment of mirers' examining boards.** It is identical with the Heffran House bill introduced Feb. 19.

Representative Chaplin, Cambria County, has **introduced a bill** duplicating that of Senator Stineman's measure in the upper house, intended to protect bituminous-coal miners in the determination of the amount of coal to be used as the basis for calculating wages.

A measure that was defeated two years ago has been introduced by Representative Staudenmeier, Schuylkill County. **The bill would regulate the sale of anthracite and fix standards of size.**

Representative Thomas, Luzerne County, has offered a bill in the House that **requires the carrying of mine water from mines and washeries to streams and rivers in proper sluices or drains.** It is unlawful to permit this water to flow over the land. Overflows and leaks are not allowed. A fine of $100 a day is provided for violations.

Representative Post, Washington County, **introduced a bill** in the House March 27 **to relieve life tenants of land from payment of taxes on underlying veins of coal which they have no right to operate.** The bill provides that the owner of the veins shall pay the taxes. The owner is to be assessed up to an amount equal to the taxes on similar acreage of coal in the same vicinity and the life tenant shall only be required to pay the residue of the taxes assessed on the land after deducting the portion of the tax required to be paid by the owner of the veins of coal. Assessors are empowered to assess coal and surface separately in cases where the life tenant of land has not the right to operate the coal underlying the surface.

A Court of Industrial Relations, to consist of three judges, is created by a bill introduced in the House by Representative Parkinson, Greene County. The court would have jurisdiction over mining industries, those engaged in the manufacture and transportation of food and clothing and would have power to investigate controversies arising between employer and employee or between groups of workers in these industries. Its powers extend under the provisions of the bill to wages, working and living conditions and the conduct of the industries. The judges would be named by the Governor and would receive $5,000 a year and serve for four years. The proposed court would sit at Harrisburg.

A bill introduced last week by Representative O'Boyle, Lackawanna, **requires owners and operators of coal mines and operations to furnish coal at current prices for the use of hospitals, poorhouses and other charitable institutions, schools, churches and buildings of municipal or quasi-municipal character.** A provision in the bill is that the mine owner may demand that the coal be paid for at the mine.

Bituminous-coal companies recently incorporated in Pennsylvania are as follows: **Monongahela Fuel Co.**, Pittsburgh; capital $25,000; treasurer, John Robinson, Pittsburgh; incorporators, John Robinson, Jr.; H. L. Robinson and David P. Lindsay, all of Pittsburgh. **W. R. Calverley, Inc.**, Pittsburgh; $5,000; Harry V. Wyld, Pittsburgh, treasurer; incorporators, Walter R. Calverley, Joseph G. Calverley and Harry V. Wyld, Pittsburgh. **Sterling-Graham Coal Co.**, Masontown, $150,000; W. W. Sterling Graham, Masontown, treasurer; incorporators, William L. Graham, Estella S. Graham and E. W. S. Graham, Masontown. **Godfrey Hill Coal Co.**, Irvona; $10,000; E. W. Turley, Irvona, treasurer; incorporators, E. W. Turley, G. W. Turley and B. M. Turley, Irvona. **Browns Run Coal Co.**, Uniontown; $50,000; Amedee J. Hagan, Uniontown, treasurer; incorporators, Amedee J. Hagan and Altha M. Craig, Uniontown and James S. Rush, Masontown.

At the annual election of the Pittsburgh Coal Co., March 28, F. J. LeMoyne, formerly secretary, was chosen to succeed F. M. Wallace, vice president in charge of finance. Mr. Wallace resigned to give his attention to his banking interests in Erie, where he is president of the First National Bank. The other officers elected were: President, W. F. Field; Vice-President in charge of operations, J. A. Donaldson; Vice-President in Charge of Sales, James H. Woods; Vice-President in Charge of Ohio and Kentucky operations, G. C. Weitzell; Vice-President and Comptroller, J. B. L. Hornberger; General Counsel, Don Rose; Secretary, Aaron Westlake; Treasurer, A. F. Fell; Auditor, J. D. McPherson. Vacancies among the directors were filled by electing George B. Taylor, Henry Oliver Rea and Peter Reiss.

Thirteen miners after being entombed for ten hours in the No. 1 drift of the Nesquehoning mine of the Lehigh Coal & Navigation Co., in Panther Creek Valley, **were released in good health** and removed to their homes in automobiles.

Bids for the sale of anthracite veins underlying the River Common at Wilkes-Barre were opened March 28. James J. Powell, of Scranton, presented a bid of 52c. a ton, explaining that the minimum amount to be paid the city would be arranged by him and council if he is awarded the contract. Mr. Powell is believed to represent the Glen Alden Coal Co. The second bid was from James F. Bell, also a Scranton attorney, who it is believed represents the Hudson Coal Co. His bid was 47c. a ton, with $10,000 as a minimum to be paid the first year and $25,000 as the minimum to be paid during succeeding years.

John Collins, of Nanticoke, **has announced his candidacy for secretary-treasurer** of District No. 1, United Mine Workers of America. Mr. Collins is a former president of the district. In addition to W. J. Brennan, the president of the district, other candidates for that office are Rinaldo Cappelini and P. J. Philbin.

Production of coal in the Second Bituminous district during 1922 was 5,395,115 tons, according to the report of C. B. Ross, mine inspector. This is an increase of 1,373,641 tons over 1921. Coke production during the year was 1,091,676 tons, as compared with 377,041 tons in 1921.

The Pennsylvania Coal Co. in a communication to the Board of Education of Olyphant stated that it would **erect a new two-story school building at Underwood** on account of the increasing number of children attending the schools there. The board will co-operate with the company in selecting a site for the building.

Following the annual meeting of the stockholders of the **Bertha Coal Co.**, Pittsburgh, and the Consumers' Fuel Co., an associated interest, held March 21 in the company offices, Chamber of Commerce Building, the board of directors of the respective companies **re-elected John H. Jones president** for the ensuing year. **Isaac J. Jenkins was re-elected president of the Consolidated Fuel Co.**, which also is an associated interest.

Madeira, Hill & Co., removed their offices on March 30 from the North American Building to 260 South Broad Street, Philadelphia.

TENNESSEE

The Enterprise Foundry & Machine Works, Bristol, has **changed its name to the Enterprise Wheel & Car Corporation.** There has been no change in officers, sales force or shop organization.

UTAH

The Columbia Steel Corporation has awarded to the Link-Belt Co. a contract for the steel structure and machinery for its 4,000-ton tipple. As far as capacity is concerned this will be **the largest tipple in the Rocky Mountain region.** Its cost is probably only exceeded by the tipple of the United States Fuel Co.'s Blackhawk mine.

The **Badger Coal & Lumber Co.**, Ogden, has been reorganized. S. F. Norton becomes manager and treasurer of the company. O. P. Badger will be president. The organization is being enlarged with a view to doing a bigger business.

The Mutual Coal Co. has purchased the property of the Moreton Coal Co. in Carbon County. The consideration is said to have been $350,000. The Mutual will now become one of the largest producers in the state with an output of 1,000 tons per day. The acreage involved totals 380. It adjoined the Mutual's property. This company will now be in a position to mine a single vein of coal throughout its entire holdings, which run into 2,000 acres.

Four miners who risked or lost their lives in attempting to save their fellow workers **have been awarded gold hero medals** by the Joseph A. Holmes Safety Association, which annually selects distinctive acts of bravery in the mining industry. The presentation of the medals will form a portion of the program of the Seventh International First Aid and Mine-Rescue meet to be held in Salt Lake City, Utah, on Aug. 27, 28 and 29, under the auspices of the U. S. Bureau of Mines. **Warren A. Hoy, Frank Carter and Peter G. Rumpf**, all of whom were employed in the Lincoln Colliery, Rausch Creek, Pa., are awarded medals for rescue work when three men were overcome by dynamite fumes in a drainage tunnel. Carter, one of the men overcome by the fumes, was revived and without assistance re-entered the tunnel and rescued one of the men who was yet in the tunnel. Hoy lost his life and the medal awarded him will be presented to his widow, Lilliam M. Hoy, Tower City, Pa. The fourth medal is awarded to **William H. McKiernan**, who lost his life after rescuing a fellow miner from black damp in the bottom of a coal mine shaft on the property of J. M. Williams, Kimberly, Mo. The medal will be presented to his widow, Cora A. McKiernan.

VIRGINIA

The L. A. Snead Co., Washington, D. C., announce the opening of a Norfolk office at 515-17 Flatiron Building. S. T. Snead will be manager of the new office, but will continue to give a portion of his time to the accounting business.

The City of Norfolk rejected all bids received for supplying the city with 12,000 tons of coal during 1923. The Stewart Coal Co. bid low, at $3.65, the L. A. Snead Co., next with $4.10, and C. G. Blake & Co., third with $4.50. There were no other bids. The specifications called for New River or Pocahontas run-of-mine coal at the mines.

Clyde E. Smith has been named president of the High Carbon Coal Corporation, at Pulaski, and H. V. Smith has been elected secretary. The company was recently incorporated with a capital of $150,000.

WASHINGTON

The annual spring excursion of the College of Mines, University of Washington, was made this year from March 21 to 27 to the property of the **Britannia Mining & Smelting Co.**, on Howe Sound, British Columbia. The party of thirty, under the direction of Dean Milnor Roberts and Prof. Joseph Daniels, divided its time between the Britannia mine and the new concentrating plant of 5,000 tons capacity which recently went into operation. C. P. Browning, general manager, accompanied the party during its stay.

WEST VIRGINIA

Owing to an increase in the revenue from the gross sales tax law in this state during the first quarter of nearly $400,000 as compared with the corresponding quarter of 1922, it is estimated now by the State Tax Commissioner that **it will not be necessary to fix rates on coal** and other commodities **quite so high as was originally contemplated** when the Arnold bill was introduced at the initial session of the Legislature. Instead of a rate of 1 per cent on the value of all coal produced and sold, it would be necessary to impose a rate of only $\frac{3}{4}$ of 1 per cent as against the rate of $\frac{5}{8}$ of 1 per cent now provided by law, or $8 as against $4 per thousand dollars' sales proceeds. In other words the rate would be just doubled. It is probable that the Legislature of West Virginia will pass either the Arnold bill with the rates fixed as above or the Zimmerman bill which carries a rate of 1 per cent on the gross value of all coal mined and shipped. The gross sales tax law is now yielding a return of about $1,000,000 a quarter, or approximately $4,000,000 a year. If the rate is increased as proposed it would yield a total revenue of $5,400,000 a year, it is estimated.

The Dry Fork Smokeless Coal Land Corp., chartered under the laws of Virginia, has been granted authority to do business in West Virginia.

An important deal has just been consummated under the terms of which **C. H. Mead**, of Beckley, **has disposed of his holdings in the Ingram Branch Coal Co.** to Lynchburg interests. James Gorman, of Lynchburg, has been elected president of the purchasing company.

By May 1 the **Fenimore Collieries** at Freedie, in Boone County, expect to be in a position to operate, as development work is proceeding rapidly. A number of miners' dwellings are being erected and a town established at the seat of operations of this company.

One of the largest companies recently organized in northern West Virginia is the **Morgantown Gas Coal Co.**, which is capitalized at $3,000,000 and which will have its general office at Morgantown. James A. Paisley, extensively interested in West Virginia mining properties, is one of the larger stockholders in the new concern and associated with him are Gordon W. Wilcox, of Cleveland; Stephen Arkwright of Fairmont; Ross I. Davis and John McCarlney Kenney, of Pittsburgh; John Schweinsburg, of Parnassus, Pa.; P. W. Sherman, of Lakewood, Ohio; Thomas Skillcorn and John J. Snure, of Wheeling.

The Bear Run Coal Co. has been authorized to change the location of its principal office from Tioga to Richwood and to increase its capital stock from $5,000 to $25,000.

Officials of the United Mine Workers in northern West Virginia assert that **practically all the mines in Monongalia County** within the jurisdiction of subdistrict 4 of the Miners' Union **have signed the new scale** for the next coal year and they expect every mine owner in the Monongalia section eventually to sign the new scale. This scale will be effective from April 1, 1923, to March 31, 1924. James McCleary, district organizer, said late in March that there were only about eight independent operators in the Morgantown district who had not signed the scale and he did not expect any difficulty with the cases remaining to be settled.

WISCONSIN

Dissolution of the Wisconsin Coal Committee is presaged by a report issued by Paul E. Pressentin, secretary of the committee, detailing the accomplishments of that body. The report advises the people of the state to buy their supplies of hard coal for next winter's use as early as possible.

The Valley Coal Co., of Milwaukee, has been reorganized under the name of **Valley Coal & Dock Co.** B. M. Ainesworth is president; R. L. Clements, general manager; F. F. Kegel, treasurer; and J. F. Sweeney and F. H. Baker, directors. The company's dock is on the Menomonee River, just west of Muskego Ave.

Clifford F. Messinger, for the past three years general sales manager of the Chain Belt Co., Milwaukee, **has been elected second vice-president**, according to an announcement just made by the company.

WYOMING

Production in the southern Wyoming coal fields was the lowest in 1922 in the past 11 years, according to the annual report of Mine Inspector Robert T. Sneddon. **The total last year was 4,453,000 tons**, a decrease of 983,576 from the 1921 total of 5,436,576. There were 18 fatal accidents and 276 non-fatal accidents, giving a fatality rate of 2.7 per 1,000 men employed. The average number of miners working was 6,620, or 1,054 more than in the previous year.

WASHINGTON, D. C.

Plans for systematic research in the matter of **fireproofing mine timbers** were discussed at a recent conference in Washington attended by George S. Rice, chief mining engineer of the Bureau of Mines; W. J. Loring, former president of the American Mining Congress, and a representative of the Madison laboratory of the Forest Service. It is hoped that some material may be found which can be used as a coating for mine timbers which will at once preserve them from decay and make them slow burning if it is impossible to devise a substance which would render them entirely fireproof.

The Bureau of Supplies and Accounts, Navy Department, solicits **bids for the transportation of one cargo of approximately 5,000 tons of Navy coal** from Hampton Roads, Va., to Navy Yard, Boston, Mass., in vessel of American registry. The loading date at Hampton Roads will be about April 18, 1923. The guaranteed daily discharge rate at Boston is 500 tons. Bids will be opened at noon, April 11.

The Navy Department awarded the following contracts for coal for navy yards and naval stations March 26 on the basis of bids opened March 22: W. H. Bradford Co., Philadelphia, 14,000 tons for delivery at New York, at $5.92 per ton; Maryland Coal & Coke Co., Philadelphia, 5,000 tons, for delivery at Philadelphia Navy Yard, at $6.10 per ton; 2,500 tons for delivery at coaling piers, Philadelphia, $5.85 per ton; Imperial Coal & Coke Co., Baltimore, 10,000 tons, for delivery at Washington, D. C., at $6.17 per ton; W. A. Merrill Sons & Co., Garrett, Pa., 50 tons, for delivery at Bellevue Magazine, D. C., at $6.34 per ton; 150 tons for delivery at Alexandria, Va., $6.34 per ton; Quemahoning Coal Co., Baltimore, 4,000 tons for delivery at Annapolis, Md., at $6.49 per ton; Chesapeake & Virginian Coal Co., Norfolk, 3,600 tons for delivery at Portsmouth, Va., at $7.28 per ton.

At the request of Secretary Hoover, of the U. S. Department of Commerce, **F. M. Feiker**, assistant to the president of the McGraw-Hill Co., Inc., has again been granted leave of absence to **undertake the organization and general direction of the world surveys of raw material supplies**, rubber, sisal hemp, nitrates, for which Congress recently made an emergency appropriation of $500,000. Mr. Feiker served as assistant to the Secretary of Commerce during the first year of Mr. Hoover's administration, acting as general assistant in organizing the personnel and industrial trade contact committees in relation to the Bureau of Census, the Bureau of Standards, and the Bureau of Foreign and Domestic Commerce. Out of his nine months' work came the monthly statistical survey of the Bureau of Census, the Division of Simplified Practice of the Bureau of Standards, Commerce Reports in new form, and fifteen so-called commodity divisions of the Bureau of Foreign and Domestic Commerce.

CANADA

COAL OUTPUT OF BRITISH COLUMBIA, FEBRUARY, 1923

VANCOUVER ISLAND DISTRICT

Mine	Tons

CROW'S NEST PASS DISTRICT

Crow's Nest Pass Coal Co., Coal Creek	48,038
Crow's Nest Pass Coal Co., Michel	33,971
Corbin Coal & Coke Co., Corbin	7,205
Total	89,214
Grand total, February	244,052

Anthracite imported by Canada from the United States during 1922 totaled 2,514,249 net tons, compared with 4,567,370 net tons in 1921 and 4,912,964 net tons in 1920. Imports of bituminous coal from the United States during the year amounted to 10,924,645 tons, as against 13,536,250 tons in 1921 and 15,902,632 tons in 1920. For the first time in many years coal was imported from Great Britain, about 817,000 tons having arrived during the last six months of the year.

The coal miners in **District 18**, United Mine Workers of America, numbering upward of 9,000, have **voted to accept the agreement fixing the wages for 1923** signed by their representatives and the Western Canada Coal Operators' Association.

The new shaft of the Dominion Coal Co. at O'Neil's Point, to be known as Dominion No. 26 Colliery, when completed will be, next to Dominion No. 2 Colliery, the biggest coal producer of all the mines of the Dominion Coal Co. At the end of February the shaft had been sunk to a depth of 441 ft. The total depth of the shaft when completed will be 670 ft., and with the fast rate of progress that is now being made **it should be ready to hoist coal by the middle of May.** The work of the sinking of the shaft is under the direction of W. H. Graham, construction superintendent of the Corporation, with W. H. Metcalf in charge of actual operations.

S. H. Butt, president and general manager of the Little River Coal Mining Co., of St. George's, Newfoundland, has announced that **boring will be commenced on his company's areas during this month.** It was also said that the new 4½-in. core drill recently purchased by the L. R. C. M. Co. had been shipped and will have a depth capacity of 2,000 ft. The company controls an area of coal lands of eleven square miles.

The East Wellington Coal Mines Ltd. has been incorporated **to develop coal lands situated west of Nanaimo** and adjacent to the abandoned workings of the "Jingle Pot" mine. H. W. Maynard is the president and J. J. Grant, the general manager. Good progress already has been made in the driving of the slope. The railway and wharves, together with much of the other plant of the old "Jingle Pot" are to be used. It is expected that production will be started within a month and that an output of 1,000 tons a day will have been reached in six months. It is the Wellington seam that will be exploited. Where it has been struck at a depth of 1,100 feet it is 5 ft. 6 in. thick. The property, it is estimated, will produce 6,000,000 tons.

The Webster Manufacturing Co., of Chicago, Ill., and Tiffin, Ohio, announces the organization of a new corporation, the **Webster-Inglis, Ltd.**, Toronto, Ont., which will design and manufacture elevating, conveying and power transmission machinery along the same lines as now manufactured by the Webster company.

Uehling Instrument Co., Paterson, N. J., manufacturer of C.O.2 recording instruments, has appointed the Combustion Engineering Corporation, Ltd., with head office in Toronto, and branches in Montreal, Winnipeg and Vancouver, as its Canadian sales agent.

Obituary

Alfred M. Shook, age 77, died at his home in Nashville, Tenn., March 18. Colonel Shook was one of the early developers of coal and ore properties in the Birmingham district and also was a pioneer in iron and steel manufacture. He was prominently identified with the early operations of the Tennessee Coal, Iron & Railroad Co. in Alabama and Tennessee and was vice-president and general manager of the corporation for a number of years. At the time of his death he had retired from many of his activities but was president of the Brush Creek Coal Co., a Tennessee colliery, and was identified with banking institutions in Nashville, a trustee of the Mutual Life Insurance Co. of New York, and was active in civic and religious work in his home state.

Frederic A. Potts died at his home in Lakewood, N. J., Saturday, March 24, in his 63rd year. He was the head of F. A. Potts & Co., wholesale anthracite coal dealers, 143 Liberty Street, New York. He was a member of the Lakewood Country, Union, Turf and Field, St. Anthony and Rumson clubs and the St. Nicholas Society. He had resided in Lakewood for twenty-five years. He leaves his wife and one son, David F. Potts.

Traffic News

The Interstate Commerce Commission, after a further hearing, rendered a decision March 5 in docket No. 10197, **The Avella Coal Co. et al. vs. the Pittsburgh & West Virginia Ry. Co.** and the Director General of Railroads, as agent. Finding that undue prejudice existed in the distribution of coal cars the **commission ordered that the defendant pay unto the complainants** named hereinafter on or before June 1, 1923, the amounts set opposite their respective names, with interest thereon in each case at the rate of 6 per cent per annum from March 22, 1918, as reparation: Avella Coal Co., $10,745.56; Duquesne Coal & Coke Co., $26,584.58; David L. Newill, receiver of Pittsburgh & Southwestern Coal Co., $3,451.33; Waverly Coal & Coke Co., $7,581.88; Meadow Lands Coal Co., $17,559.99. It was further ordered that **James C. Davis, Director General of Railroads,** as agent, be **directed to pay unto the complainants** named hereinafter on or before June 1, 1923, the amounts set opposite their respective names, with interest thereon in each case at the rate of 6 per cent per annum from March 22, 1918, as reparation on account of unduly prejudicial practices in the distribution to complainants' mines of coal cars for use in interstate commerce: Avella Coal Co., $1,036.08; Duquesne Coal & Coke Co., $28,558.53; David L. Newill, receiver of Pittsburgh & Southwestern Coal Co., $7,347.45; Waverly Coal & Coke Co., $735.37; Meadow Lands Coal Co., $1,671.47. The complaints of the Pryor Coal Co. and the Ferguson Coal & Coke Co. were dismissed for lack of proof of damage.

The Louisville & Nashville R.R. on March 19 **placed contracts with several car-building concerns for 8,000 cars,** of which 6,000 are steel coal cars, the contracts also including thirty-six engines. The orders amounted to over $18,000,000. The Pittsburg Pressed Steel Car Co. got the order for 6,000 coal cars.

C. A. Pennington, superintendent of terminals of the Cleveland, Cincinnati, Chicago & St. Louis R.R. (Big Four) and also for the Chesapeake & Ohio R.R., on March 21 stated that plans have been made for **spending $7,000,000 in rebuilding and double tracking the C. C. C. & St. L. bridge across the Ohio River at Louisville,** which will materially reduce terminal congestion there. This bridge has not been used for some time in handling the heavier coal trains or big locomotives, resulting in breaking up of trains at Louisville and remaking at Jeffersonville, Ind., which has retarded big coal movement through Louisville materially.

Coal users operating on the Norfolk waterfront will have to provide their own barges for hauling coal supplies after April 15. **The Norfolk & Western and Virginian railways have published tariffs** effective that date **discontinuing the barging practice** in the inner harbor. A protest has been made to the Interstate Commerce Commission by the Chamber of Commerce and representatives of both coal dealers and consumers, seeking to have the proposed regulation revoked.

Colonel H. C. Nutt, president and general manager of the Monongahela Ry., **denies a report** coming from some purchasing agents for railroad companies or purported to have been made by them to the effect **that the Monongahela Ry. would not honor assigned-car orders.** Colonel Nutt said: "This company has been accepting cars of railroad ownership for loading fuel coal for the owning company ever since the car shortage developed last fall and expects to continue the practice unless and until it is prohibited by the Interstate Commerce Commission or other competent authority." Wholesalers in Morgantown, W. Va., report having had considerable difficulty with old customers who refused to enter into new contracts and several assigned as the reason that co-operation could not be obtained from the Monongahela Ry.

On account of accumulation **an embargo was placed March 30 by the New York Central R.R.** against the acceptance of all shipments of bituminous coal from New Jersey Central R.R. stations and from all connections at all junctions for points on or via the Boston & Maine R.R., except B. & M. R.R. fuel.

Coming Meetings

National Retail Coal Merchants' Association will hold its sixth annual convention June 25, 26 and 27 at Scranton, Pa., with headquarters at the Hotel Casey. The registration fee of $15 will include all meals except breakfast, transportation to and from the mines which will be visited, and the banquets. The only other expenses to be incurred will be hotel room and transportation to and from Scranton. Executive secretary, J. E. O'Toole, Philadelphia, Pa.

National Safety Council will hold its twelfth annual safety convention at the Buffalo Statler Hotel, Buffalo, N. Y., Oct. 1-5. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

International First-Aid and Mine-Rescue meet will be held Aug. 27-29, at Salt Lake City, Utah.

American Institute of Electrical Engineers will hold its annual convention June 25-29, at Swampscott, Mass. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

Coal Mining Institute of America will hold its annual meeting Dec. 19, 20 and 21 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Chamber of Commerce Building, Pittsburgh, Pa.

The Virginia Coal Operators' Association will hold its annual meeting on April 21 at Norton, Va. Secretary, G. D. Kilgore, Norton, Va.

International Railway Fuel Association will hold its spring convention at the Hotel Winton, Cleveland, Ohio, May 21-24. Secretary-treasurer, J. G. Crawford, Chicago, Ill.

The American Mining Congress will hold its twenty-sixth annual convention in conjunction with the **National Exposition of Mines and Mining Equipment,** Sept. 24-29, at the Milwaukee Auditorium, Milwaukee, Wis. Secretary, J. F. Callbreath, Washington, D. C.

Indiana Retail Coal Merchants' Association will hold its annual meeting April 25 and 26 at the Severin Hotel, Indianapolis, Ind. Secretary, R. R. Yeagley, Indianapolis, Ind.

American Society for Testing Materials will hold its annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, N. J., beginning June 25 and continuing throughout the week. Secretary, E. Marburg, Philadelphia, Pa.

The Colorado & New Mexico Coal Operators' Association will hold its annual meeting June 20 at Denver, Col. Secretary, F. O. Sandstrom, Denver, Col.

The Electric Power Club's annual meeting will be held at the Homestead, Hot Springs, Va., June 11-14. Executive secretary, S. N. Clarkson, Cleveland, Ohio.

National Foreign Trade Council will hold its annual conference May 2-4 at New Orleans, La. Secretary, O. K. Davis, 1 Hanover Square, New York City.

The eleventh annual meeting of the Chamber of Commerce of the United States will be held in New York City May 7-10.

National Coal Association will hold its sixth annual convention June 19-22 at Atlantic City, N. J. Assistant secretary, C. C. Crowe, Washington, D. C.

The Canadian Retail Coal Association will hold its nineteenth annual convention at the King Edward Hotel, Toronto, Ontario, Canada, on April 12 and 13. Secretary, B. A. Caspell, Brantford, Canada.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 23 NEW YORK, APRIL 12, 1923 Number 15

Fair and Timely Warning

RAILROAD activity exceeding anything so far recorded is forecast by the American Railway Association in an announcement issued last week. Taking time by the forelock the railroad executives have outlined and agreed upon a program that calls for a reduction in bad-order cars and locomotives to normal by Oct. 1, for a minimum of road construction and maintenance after Sept. 1 and that stocks of railroad fuel coal for next winter be put in the ground by Sept. 1. Above all in interest to the coal industry, however, is the implication that a car shortage is on the way and that it will be of huge proportions next autumn unless many things are done.

The warning is timely and fair. The roads are expending something over $1,500,000,000 for equipment and betterments in two years and they may fairly ask the shipping public to co-operate with them in meeting the transportation needs of the country. Between Jan. 1, 1922, and March 1, 1923, the roads of the country have purchased and there have been delivered to them 117,280 new freight cars and 2,106 new locomotives. More than 100,000 more cars and 1,000 locomotives are on order and will be delivered by Oct. 1, 1923. The railroad executives believe that they are doing their utmost to prepare themselves for the deluge of traffic that they see coming. They ask the country to help.

It is quite true, as pointed out by the *Railway Age*, that "there is very good reason for believing that as the activity of business increases the shortage of transportation will be felt more actively than ever before, because it is far greater than any but a few people realize." The shortage has been with us since the coal strike was terminated last August, and because it affects all kinds of freight it is a factor to be considered in forecasting the program this year of general business expansion. There may be, as has been pointed out, a definite relation between available transportation and credit expansion, for if producers of manufactured goods cannot make deliveries they must increase their loans to carry stocks, or curtail production.

Literal fulfillment of the agreement among the railroads to complete their normal proper stocking program of fuel coal by Sept. 1 will have its effect on the soft-coal trade this summer. A fuel coal consumption of 400,000 tons per day, or 150,000,000 tons per year, is indicated by the present and expected railroad activity. Thirty days' supply—a fair normal average for winter—by Sept. 1 means at least the doubling of present stocks, or the addition of 6,000,000 tons this summer. If the roads should get their stocking program well under way within the next thirty days, they would have fifteen weeks remaining for its completion, or an average of 400,000 tons per week of storage coal to originate, move and put down. Such an increment to the usual summer requirements of the country will help hold up the rate of production.

This tonnage will be on contract and negotiation of fuel-coal contracts is well under way. Some of the largest buyers, as the New Haven and the New York Central, have been closing contracts during the past week. An early decision of the Interstate Commerce Commission on the assigned-car case will facilitate the buying program, particularly if it be in the direction of restricting this method of getting fuel coal.

The railroads urge the public to buy and store coal this summer. The Federal Fuel Distributor gives the same advice, likewise the U. S. Coal Commission. The navy purposes, as an example, to put some 200,000 tons into stock at once. If buyers, particularly the railroads and large industrials, take advantage of their opportunities this summer and get a large part of next winter's coal off the rails, they will most certainly have more transportation for their products and less car shortage than if they do otherwise. The incentive is not so great nor the reason so clear as that which preceded the accumulation of huge reserves prior to April 1, 1922, but it is before us nevertheless.

Virtuous Indignation at Brophy

JOHN BROPHY, president of district No. 2 of the United Mine Workers, is not popular at headquarters. That is quite apparent from the last issue of the *United Mine Workers' Journal*. His friends on the outside, who have supported his drive against the non-union fields in Somerset County, his nationalization program and his general liberal policies are cartooned as riding for a fall. The *Journal* vigorously assails the tactical error of his legal representative in declaring before the Interstate Commerce Commission that the mine workers would accept a 20-per cent reduction in wages if the assigned car were abolished. At the same time Brophy's lone efforts to continue the strike in Somerset County get no support from the official organ of the union.

It happens that Brophy is acknowledged by many as the strongest opponent of John L. Lewis, which explains much, inasmuch as Lewis may be supposed to control the policy of the *Journal*. Brophy is a real "liberal," and to the following he has attained on that account are to be added those who go along because they are opposed to Lewis, among whom are such as Farrington and Howat.

Intermingled with the shafts aimed at Brophy, the *Journal*, editorially and in its news columns, stresses the law-abiding character of the miners' union. To break the law or any man's head is farthest from its purpose, it seems. Ellis Searles' letter to John Brydon, of the operators' association, makes it clear that were there to be any measure of violence in Somerset County, which is in Brophy's jurisdiction, it would be no fault of the International union—far from that headquarters to countenance trouble! One can almost see the finger pointing at Brophy, who is at least suspected of having

"reds" about him. Indianapolis with much show of virtue declares that it will have no reds in its ranks.

But why pick on Brophy in this fervor of spring housecleaning? Lewis' drive on the reds in his organization and the double repudiation of the acts of Brophy are converging. One may be pardoned for suspecting that Brophy is to be made the goat. And yet what has he done? Was the Herrin massacre in district No. 2? Was the Cliftonville episode in Somerset County? Did Brophy engineer the Willis Branch attacks or command the armed march on Logan County?

So far as we know, the only laws that Brophy and his liberal-minded friends would violate are economic laws. The gentle folk who hold his radical views—or should we say, whose radical views he holds?—are more given to the use of the pen than the gun. They seek not to destroy the law but to make it all in their favor. The spotlighting of Brophy cannot make us forget the bloody happenings that occurred outside of central Pennsylvania and Somerset County.

Business Cycles and the Coal Industry

NO ONE is more affected by and has less actual control over the business cycle, the ebb and flow of prosperity than the coal man, particularly the producer of soft coal. None therefore will be more interested in knowing that there is some ground for hope that that elusive thing inflation of which is concurrent with the bubble of unwarranted prosperity, is in some measure controllable and that a sober unheated study has been made with recommendations for its control.

Whether the methods recommended by the eminent committee that made the study for the President's Committee on Unemployment, the summary of which has recently been published by the Department of Commerce, will, if followed, serve to flatten out the peaks and fill the valleys of industrial activity, is a matter on which opinions may differ.

Among the proposed remedies—which include control of credit expansion, of inflation, of public construction, unemployment reserve funds and public employment bureaus—that with respect to control of private construction bears especially on the soft-coal industry. It is true, as stated, that "few subjects in recent years have attracted more attention from business men than the stabilization of business operations." It is axiomatic that the operation of coal mines at uniform rates throughout the year and from year to year is more satisfactory and in the end more profitable than going by fits and starts. But the coal man has little or no control over the factors that influence the demand for his product. Car shortage puts the brake on his operations at times of peak demand but lack of market serves as no buffer to prevent him from hitting the bottom. Where the coal companies as individuals may become factors in controlling the business cycle is in respect to extension of plant—that is, of mine capacity.

Beyond question the capacity of the bituminous-coal mines today is well in advance of the capacity of the railroads to move the coal to market or the country to consume the coal. Yet there is witnessed today a steady increase in plant capacity; new mines are being projected, built and started into production apparently with no regard for actual market requirements and presumably with no sounder justification than that other mines have been operated at a profit.

What happens to an overdeveloped industry in the way of idle capital and unemployment of workers is nowhere better illustrated than in soft coal.

Aside from the small influence exerted on the general situation by the equipping of coal mines at times of high prices and on the peak of the cycle, it must be conceded that the soft-coal industry is more the victim of business cycles than it is or can be the cause.

At Last We Know

MYSTERIOUS no longer is the origin of coal. Prof. Barton Scammell, president of the Radium Institute, at its meeting at Dover, England, asserted that he had discovered where it comes from and how it comes to be as it is. He has been making researches into the composition of the lava from Mt. Vesuvius, which is being used as a fertilizer, and he asserts that this led him to the discovery that the layers of "bind"—the "mysterious substance found on the top and bottom of all coal seams," according to the Associated Press—are identical in analysis with lava.

In both he finds the lime, iron, magnesium, potash and other elements required by plant life. On this slim ground, Professor Scammell says, we are told, that coal is a cellulose of trees and vegetable matter carbonized by hot lava, and sunk at a remote period into the depths of the earth by disturbances of the crust of the latter. So at last are all our mysteries solved.

The only difficulty is to know where first to prick a hole in Professor Scammell's bubble. Does he seriously believe that vegetable matter could be laid on hot lava without being burned? Can he tell how the vegetable matter grew in the hot lava or how it was spread in a more or less even bed over its surface? Can he explain how the sheet of lava could be laid over the vegetable matter without burning it, seeing that coals have been metamorphosed by sills of lava that did not come within many feet of the seam and have been coked in volcanic intrusions and were saved from burning apparently only by the absence of the air necessary to sustain combustion? Does Professor Scammell not know that coal is found in regions where volcanic action is absent in the coal measures themselves and in those above them?

That bind contains lime, iron, magnesium, potash and other elements required by plant life is doubtless true, but this may be asserted of more than bind and lava. It is true also of coal. Moreover, sometimes we find coal with a sandstone roof and no bind, and it does not seem to be one whit less coal despite the absence of the bed of lava or bind which Professor Scammell says is essential to the formation of that mineral. Large beds of indurated argillaceous shale or clay—thus is "bind" defined—are found in every coal field, but despite the fact that it has constituents similar to those of lava it proves singularly sterile.

Apparently, from the newspaper story, Professor Scammell thinks that what the bind needs is to be made radioactive with radio-phosphate of potash, whatever that may or might be. Maybe that is so. That chemical might be expected, if it existed, to negative the acidity of the shale. Radioactive material and phosphates of potash are expensive, but the latter doubtless would help greatly to give fertility to any kind of soil. However, while we plead guilty to a lack of agronomy, we confess that whatever faith we might have had in Professor Scammell as a guide has been quite rudely shattered by his speculations on the origin of coal.

Methods of Working Highly Inclined Coal Seams by Room-and-Pillar and by Longwall

Modifications Where Two Seams Are Mined, Where Interval Between Them Is Small and Where It Is Large—Lower Seam Kept 25 Ft. Ahead of Upper Seam—Level Roads Driven from Seam to Seam

By James S. Chalmers
Montevallo, Ala.

In SEAMS that dip heavily—from 45 to 90 deg. from the horizontal—longwall or some modification of it generally is found the preferable system of extraction, whether the seams are moderately thick or very thin. Especially is this true when the depth of the seam is as much as, or exceeds, 700 ft. The pressure at that depth is great, particularly where the seams have steep inclinations. Until they reach that depth, however, they may be worked by room and pillar.

Workings thus dipping may be approached either by shaft or slope. They should be worked in lifts measuring 500 ft. down the pitch and 2,000 ft. on the level. In each panel, near its center, carriage-, balance- and manways are driven to the rise. By means of the carriage- and balance-way the coal is lowered from any intermediate roadway to that at the bottom level of its own panel along which it is conveyed to the shaft or the slope.

General Method of Opening Up Coal Seam

Fig. 1 shows a general outline of a method of procedure detailing the manner in which these roadways should be laid out in relation to the hoisting slope. Roadways *AA* and airways *A'A'* are driven level for a distance of 1,000 or more feet. The size of the pillars *B* and *B'* depends upon the depth from surface, the inclination of the seam, the condition of the roof and floor and the nature of the coal. The carriage-, balance- and manways are laid off and driven to the rise a distance of 500 ft., room roadways being started on 56-ft. centers.

Fig. 2 shows how the workings are driven. Pillars

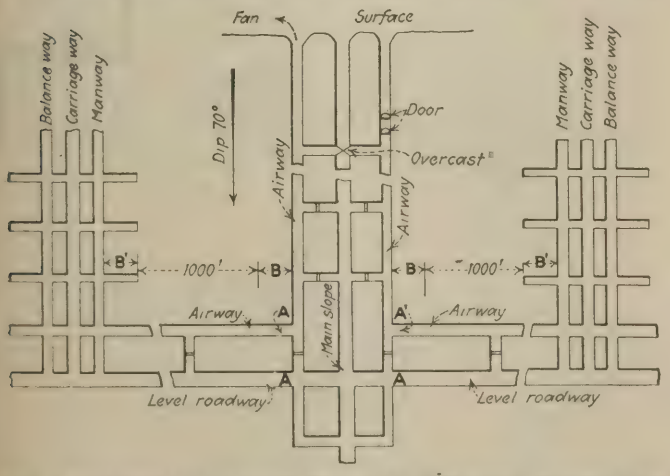

FIG. 1—GENERAL LAYOUT FOR ALL SYSTEMS DESCRIBED
The main slope with two airways goes down the full pitch of the measures. Levels are driven right and left, and from these, three roadways are driven straight up the pitch. One is a roadway in which a carriage, or cage, runs carrying a single car. A second is one in which a balance car is provided to retard by its upward movement the downward movement of the cage and to cause by its downward motion an upward motion of the cage. The third road acts as a manway.

are blocked out 40 ft. square by roadways driven 16 ft. wide so as to allow 6 ft. on the low side for the stowing of bottom rock (see Fig. 3). The pillars are cut through to the rise by crosscuts spaced on 52-ft. centers. These crosscuts are started away 7 ft. wide and are necked to 12 ft. after they have been driven 9 ft. They maintain an even width of 12 ft. until they are within 9 ft. of the roadway above, when they again are narrowed down to 7 ft. (see Fig. 4). Fig. 5 shows the

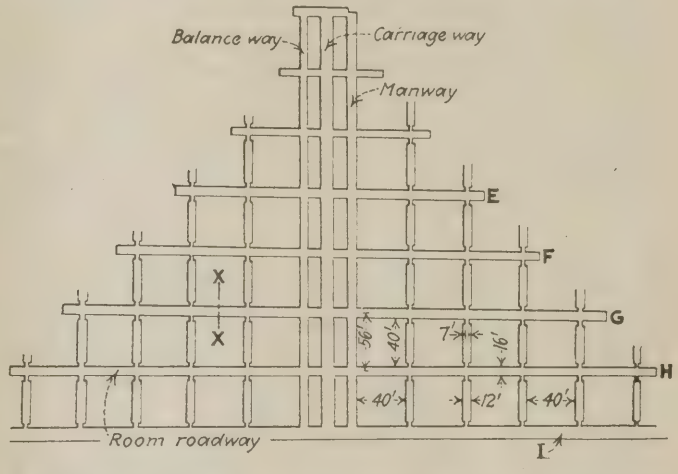

FIG. 2—PANEL LAID OUT FOR ROOM-AND-PILLAR MINING
Rooms and crosscuts are driven so as to cut the panel into pillars 40 ft. square, the rooms being 16 ft. wide and crosscuts 12 ft. wide. The dimensions are to be taken in the plane of the seam, which is 70 deg. from the horizontal.

method of laying track in a room past the point where a crosscut has been driven into it from the room below it.

The blocking out of these pillars continues till the specified length and width for the panel has been reached. It will be noticed that in laying out Fig. 2 the lower room roadways will attain their ultimate length much sooner than at the top of the panel. As soon as the first two roadways, *I* and *H*, reach the end of the panel, the pillars are brought back. Crosscuts *C* and *C'* are driven to the rise through the ribs, which are then drawn, the upper pillar, *D*, being kept 15 ft. in the lead of the lower pillar *D'* (see Fig. 6).

It should be added that a 9-ft. pillar is left above *D* to protect the room roadway *G*, (see Fig. 6). Diligent attention must be given to the timbering in the extraction of these pillars. Props should be set not more than 3 ft. apart and precautions should be taken to see that none at any time is left standing in the gob. When roadways *G* and *F* (see Fig. 2) reach the end of the panel they are brought back in the same way as *I* and *H*. The 9 ft. of coal below the lower roadway, *G*, is taken out, and 9 ft. of coal is left on the lower side of room *E*. This method is continued until all the pillars are extracted.

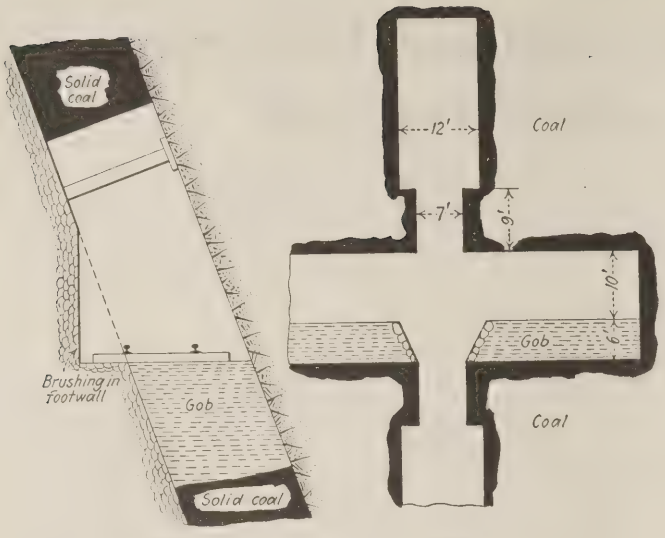

FIG. 3 FIG. 4

FIGS. 3 AND 4—METHOD OF DRIVING ROOMS AND CROSSCUTS

Fig. 3 is a sectional side elevation along the line *XX* in Fig. 2. It shows how a foothold is excavated in the footwall and how the material thus loosened is stowed in the lower part of the room. Fig. 4 is a plan on the plane of the seam.

Fig. 7 shows the method of extracting a seam by longwall. The general layout from the hoisting slope is just the same as for the room-and-pillar work. The roadways branch off every 56 ft. as before and are driven through the solid coal for a distance depending upon the dip of seam and the local conditions, thus leaving a pillar of coal to protect the entry. As soon as roadway *A* has been driven through the coal pillar the neck is widened to the rise so as to connect *A* and *A'*. When these places are connected all the coal *A* and *A'* is taken out, making the first wall of the longwall face. These connections eventually are made between the necks for the full depth of the panel.

The walls must be kept in position as in Fig. 7, wall *B* leading wall *B'* by 15 ft., wall *B'* leading wall *C* by an equal distance and so to the full height of the panel.

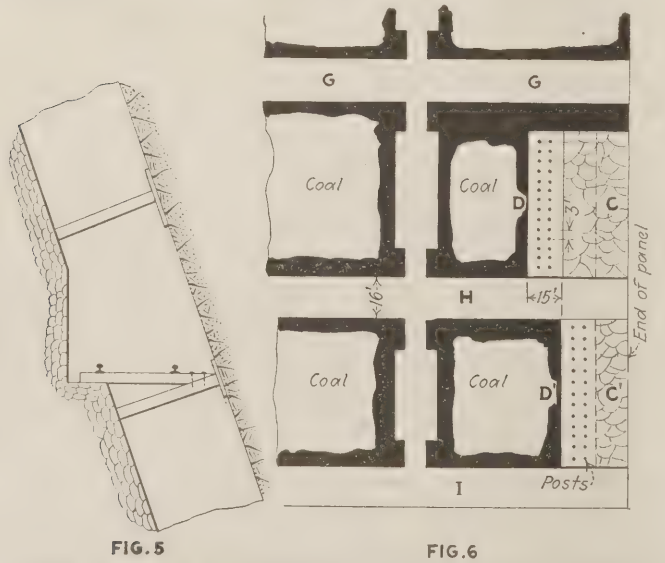

FIG. 5 FIG. 6

FIGS. 5 AND 6—SUPPORTING TRACK OVER CROSSCUT AND DRAWING PILLARS

Where the crosscuts intersect the room roadways, what closely resembles a shaft is formed in the floor of the room and the track has to rest on heavy posts each tightened by a cap. One end of the tie rests on the recess in the footwall and the other end of the tie is beveled and securely spiked to the prop, which, being only 20 deg. from the horizontal, is more like a crossbar than a post. Fig. 5 is an elevation, whereas Fig. 6 is on the plane of the seam. A 9-ft. pillar protects the upper room of the three shown.

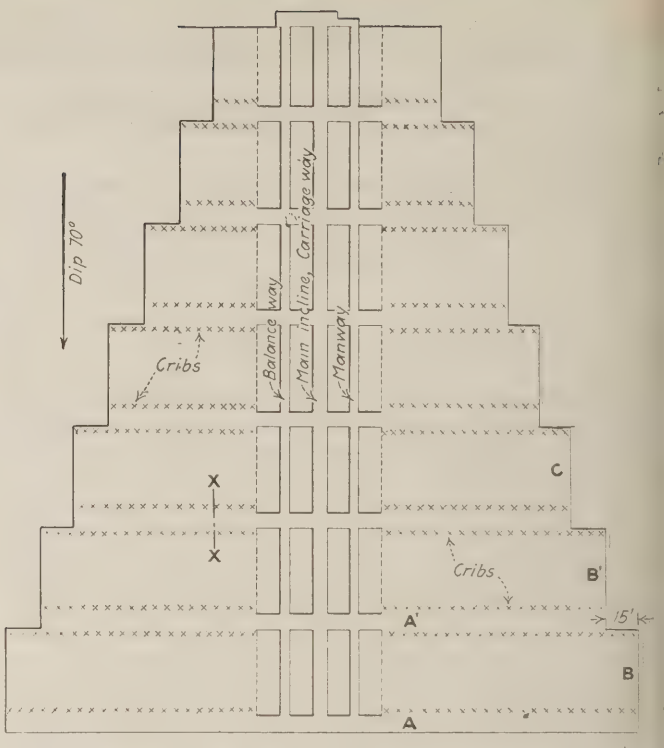

FIG. 7—MINING COAL WITH PITCHING LONGWALL FACE

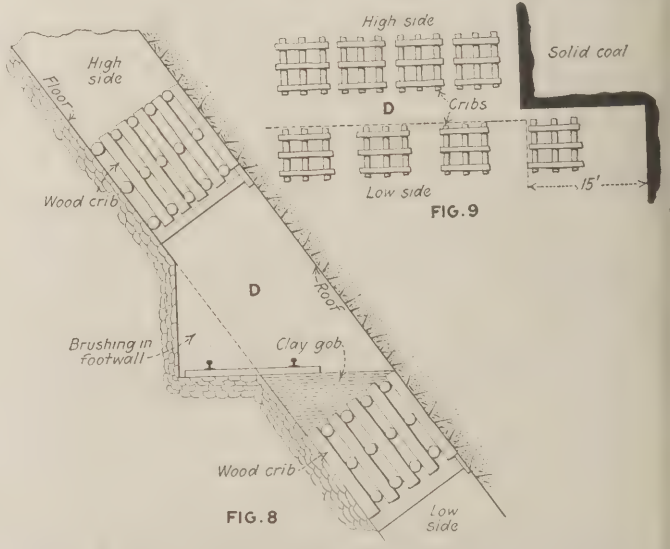
With precisely the same initial development longwall faces are started which run directly up the pitch, a pillar being left on either side of the inclined roadways. This illustration is on the plane of the seam.

Cribs of soft wood are built on both high and low sides of the roadways, as shown in Figs. 8 and 9. The footwall is brushed, as in Fig. 8, so as to afford material for leveling the track, any surplus rock being thrown into the open space in the "wall" below. The longwall workings must be timbered in a systematic manner, and the timber must be extracted from the gob in a manner equally systematic.

Fig. 10 shows a cross-section with two seams of coal having 5 ft. 6 in. of rock and fireclay between them. It also is represented as lying at an inclination of 70 deg. The triple roadways are driven in the upper seam for the full depth of the panel, and roadways are branched



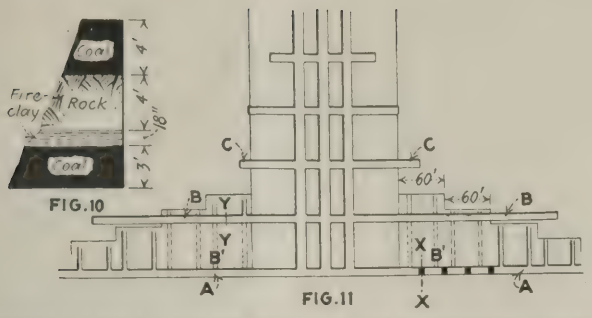


FIG. 9 FIG. 8

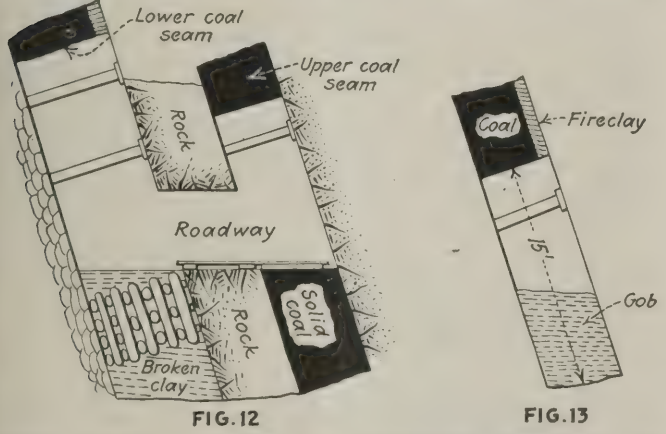
FIGS. 8 AND 9—LONGWALL GATEWAY IN ELEVATION AND IN PLAN ON PLANE OF SEAM

Fig. 8 shows how the material shot out of the footwall is used as ballast to support the road, which has to pass not so much alongside the wood cribs as resting on the sides of them. Fig. 8 shows elevation *XX* in Fig. 7. Fig. 9, which is a plan on the plane of the seam, shows how the cribs are placed and the face is offsetted.

FIGS. 10 AND 11—SEAM SECTION AND WORKING PLAN



Here the longwall face is level and not pitching. The roads pitch and not the working face. Cross-sections *XX* and *YY* in this illustration are shown in Figs. 12 and 13 respectively. The coal and fireclay together being 4 ft. 6 in. thick, enough to admit a car, no excavation in the footwall is necessary.

off as before at 56-ft. centers. Also, as before, a pillar of coal is left to protect the triple roadways. The level roadway *A* is driven first, but all the others are left standing until they are needed (see Fig. 11).

From roadway *A* in the upper seam, level roadways are driven every 56 ft. through the rock and fireclay to the lower seam. A 15-ft. slab, 60 ft. wide, is taken to the rise in the lower measure (see Fig. 12), the 18 in. of fireclay being thrown back as shown in Fig. 13. This slabbing forms the first wall. The level roadway in the lower seam being extended from level roadways from the upper seam the requisite number of walls required to reach the end of the panel are developed in turn, each wall being stepped back a few feet from the one nearest it.

These walls, as stated, are 60 ft. long and are worked to the full rise, each wall having two chutes down which the miner slides his coal, which is shoveled into cars at the end of the chute. Each chute is lined with wooden boards and cribs built as shown in Fig. 14.

As the longwall faces progress from roadway *A* toward *B*, the roadway in the upper seam is extended, and roadways are driven through to the lower seam every 56 ft. By this means the chutes have to be maintained only for the distance between the two adjacent roadways *A* and *B*. As the walls advance to roadway *C* that roadway is driven, and the same method is followed as in the roadways below. Fig. 11 shows the general outline and position of walls going to the rise in the lower seam, also the roadways in the upper seam. These latter roadways are excavated 15 ft. wide, and cross-

FIGS. 12 AND 13—LEVEL ROADS DRIVEN BETWEEN AND ALONG THE COAL SEAMS

As the seams are nearly vertical it is quite easy to drive a level roadway from the upper to the lower seam through the intervening rock. The roadways along the seam, as shown in Fig. 13, are made 15 ft. wide. The space in the lower side of the room in the lower coal seam is used for the gobbing of the fireclay removed from the roof of that measure. Fig. 12 is a cross-section taken at *XX* in Fig. 11, and Fig. 13 is a cross-section taken at *YY* in the same illustration.

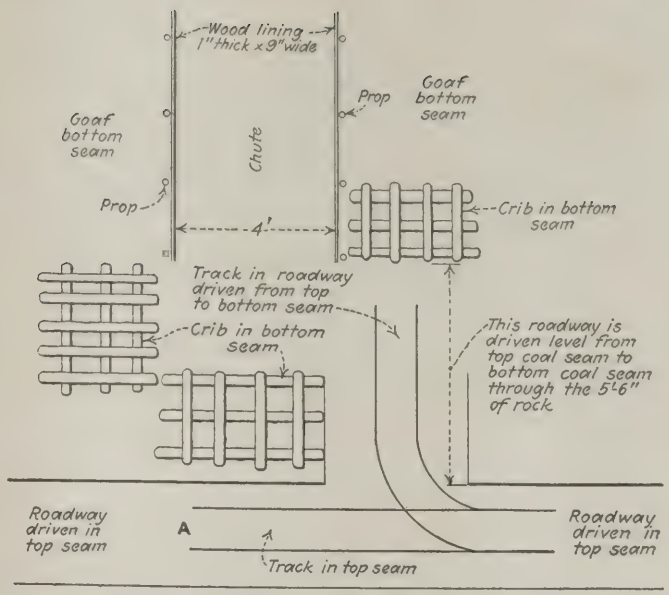


FIG. 14—CHUTE IN LOWER SEAM, ROAD IN UPPER SEAM AND BETWEEN SEAMS

Unfortunately it is not practicable to raise the chute and build a battery in the lower seam, for the quantity of coal to be dropped down the chute before its abandonment is not large. The coal, therefore, falls to a shoveling floor and not directly into the mine wagon and is loaded by a miner into a car standing on the extension of the cross road between seams.

cuts are driven to connect the roadways whenever these are needed for the supplying of air. When these roadways reach the end of the panel, as roadways *A* and *B* will first, this seam is worked back as illustrated in Fig. 6.

Fig. 15 shows two seams separated by 52 ft. 3 in. of rock and lying also at an inclination of 70 deg. Triple entries, similar to those already described, are driven in this case in the lower seam and roadways set off from them at 56-ft. centers, leaving as before the required width of pillar to protect the entries. They then are opened out by longwall, as has been described above. The lower seam only is provided with triple slopes, the upper seam being prepared for opening by passageways through the rock from the lower seam. Even though the upper seam has no triple slopes to be protected, its level roadways are also driven narrow until they reach the end of the pillar left to protect the triple entry as in Fig. 16. Level roadways are driven from the lower to the upper seam, as in Fig. 17, at every alternate roadway—that is, at *A*, *B*, *C* and similar locations (see Fig. 16)—and as soon as the top seam is reached roadways are set away to the right and left.

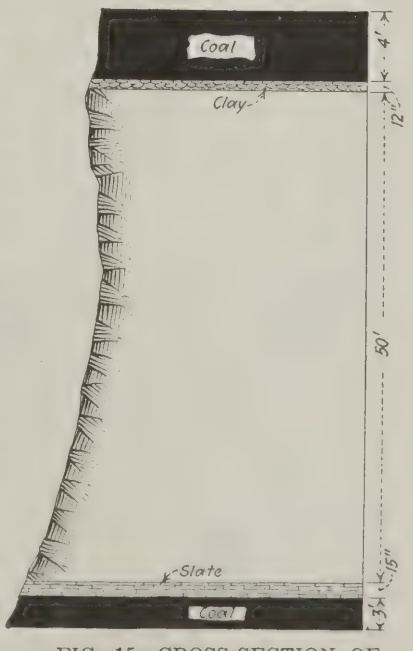

FIG. 15—CROSS-SECTION OF ANOTHER SEAM

Though these two seams are far enough apart that they usually would be mined separately, except that they would be brought to a common main slope or shaft, they are here described as being operated in close conjunction.

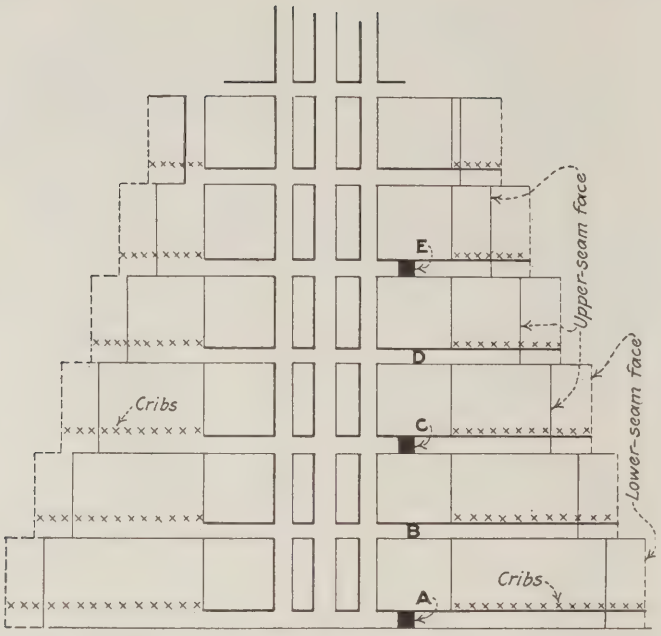

FIG. 16—LONGWALL WORKINGS IN BOTH SEAMS

The workings are kept under one another, as seen in a front elevation, which in this case is only slightly different from a plan in the plane of the coal seam. The excavations in the bottom seam are kept 25 ft. ahead of those in the upper seam.

When the roadway to the left has been driven a distance of 40 ft. an inclined road is started in the coal so as to rise one foot in four (see Fig. 18). This is continued until the slant roadway is 40 ft. from the high side of roadway *A*. Here roadway *B* is started and driven to the point at which the longwall is opened out. The same method of opening out is applied in both seams.

The line of face is stepped both in upper and lower seams, as is shown in Fig. 16. The distance between the faces of the lower and upper seams must not exceed 25 ft., the lower seam being kept in advance. In the bottom bed the 15 in. of slate in the roof is taken down and is put in the gob. In the upper seam the 12 in. of fireclay in the floor is lifted, and it also is gobbed. Lines of cribs are built on both the high and the low sides of both upper and lower seams. The floor may be lifted if necessary; this depends entirely on the size of the car being used.

Fig. 19 shows an arrangement for lowering cars from the upper of alternate roadways in the upper seam to the roadway in the same seam just below it. A roadway to the full rise of the bed is driven from *A* to *B* (see Fig. 16) to a point 20 ft. from *B'*. It is in this roadway that the balance car works. This balance is so arranged that it runs only half as far as the car. The full car on descending hauls up the balance and the balance on descending hauls up the empty car. To prevent the balance car from running back when the full car is disconnected from the rope at the foot of the slope, the rope is held fast as shown in Fig. 20. A short piece of chain is attached to the end of the rope. To this an auxiliary piece of chain is attached, the end of which can be hooked over a bolt when the car reaches the foot of the inclination. This holds the balance car in position until the empty car is attached.

Figs. 21 and 22 show a side view and plan of the arrangement at the mouth of each level road near the carriageway. Rails *AA* are built up level with the deck of the carriage (see Fig. 23). The roadway is continued at the same level as at this point and driven accordingly. Fig. 22 shows the safety and signal arrangement combined in *BB*. Fig. 23 shows a side view of the carriage, which is built specially to suit both the inclination of the seam and the size of the car. Fig. 24 shows a side view of the balance car. This is built of long and narrow cast-iron plates bolted together as shown. Fig. 25 shows the general outline of drums *D* and *D'*, carriage- and balance-ways *W* and *W'*, also the sump *S* at the bottom of the carriageway and the layout of the tracks.

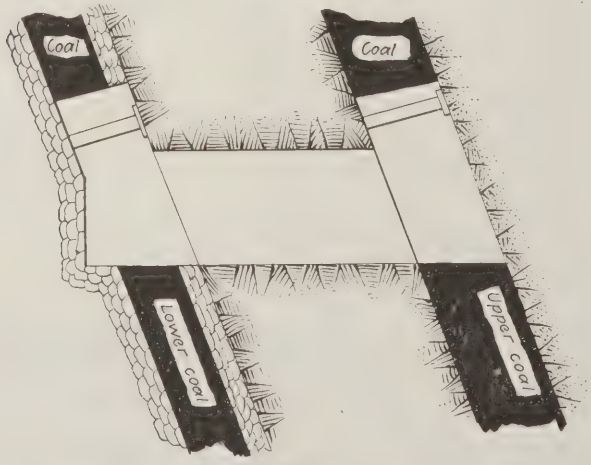

FIG. 17—SHOWING CONNECTION BETWEEN TWO SEAMS

The roadway is not driven as high as those within the seams, where the material to be excavated is coal.

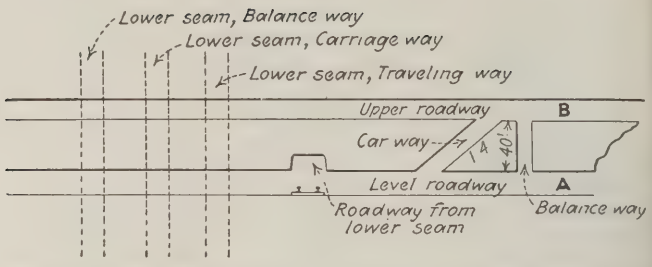

FIG. 18—HOW ADJACENT LEVELS IN UPPER SEAM ARE CONNECTED BY A 25-PER CENT INCLINE

By means of this incline the need for interseam roadways at each level is obviated.

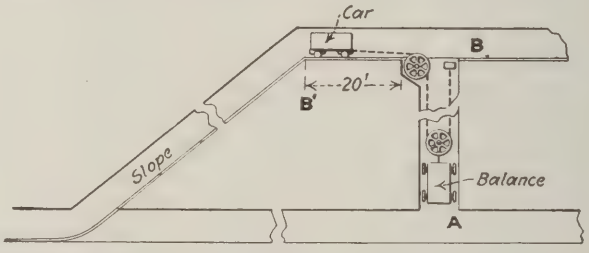

FIG. 19—METHOD OF LOWERING CAR DOWN INCLINE

The balance car travels only half as far as the coal car but on a much steeper pitch.

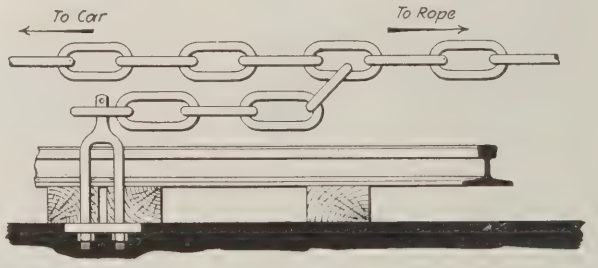

FIG. 20—CHAIN HOLDS ROPE WHEN CAR IS DETACHED

The balance car would immediately descend as soon as the car was detached, but by a hook attached to the track and a short chain, the chain by which the rope is attached to the car is held till an empty car arrives and is hooked on. Then the short chain is released.

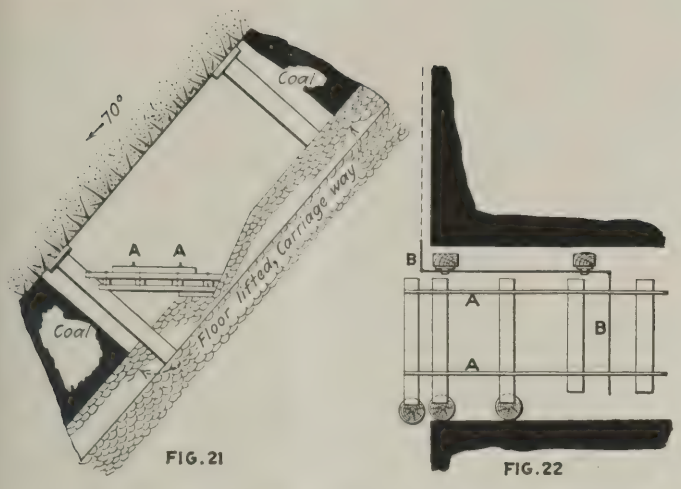

FIG. 21

FIG. 22

FIGS. 21 AND 22—SIDE VIEW AND PLAN OF LEVEL ROAD AT CARRIAGEWAY

The level road is set at such an elevation that cars can run from it to the deck of the cage as shown in Fig. 23. Fig. 22 shows not only this road but the safety and signal arrangement to prevent cars from running down the carriageway.

In operating this self-acting arrangement the rope to the carriage comes off drum *D'* at the bottom. The rope balance comes off drum *D* at the top. The balance is so loaded that in going down the inclination it will bring up the carriage with the empty car. The man operating the drums applies the brake, stopping the carriage at any landing desired. He keeps the brake tightly applied while the empty car is taken off the carriage and the full car put on. When the signal *BB* is lowered (see Fig. 22), the brake is eased off and the carriage with a full car will bring up the balance. When the carriage lands at foot of the slope into sump *S* (see Fig. 25), the deck of the carriage is level with the track on each side of the sump. The brake again must be kept tightly applied until the full car is taken off and the empty car put on.

It will be noted that both cage and balance car have long wheelbases, so that there is little chance of a derailment even if the roadway laid for these carriages is somewhat out of line.

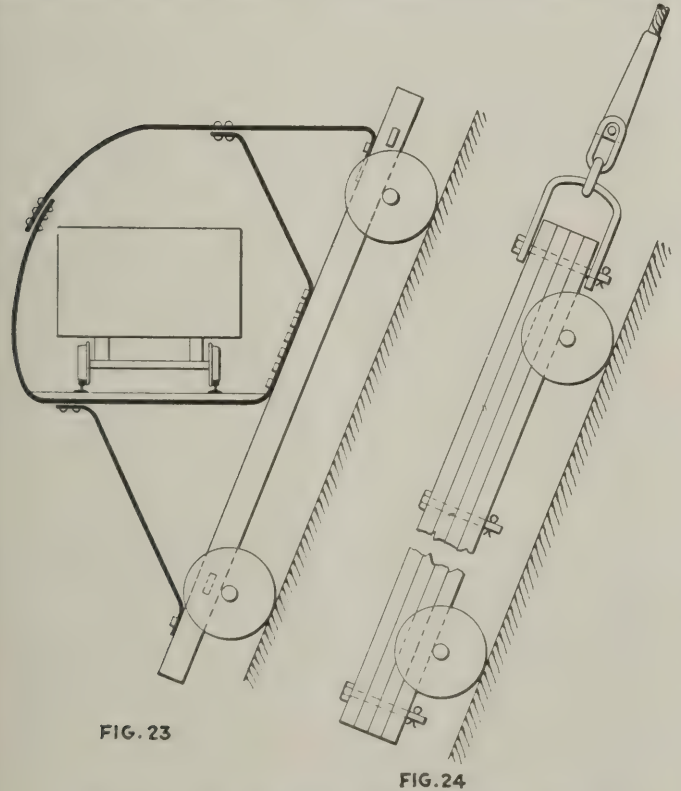

FIG. 23

FIG. 24

FIGS. 23 AND 24—CAGE AND BALANCE CAR

The car is lowered so that the surface of the coal is as level when in the cage as when it is hauled along the longwall gateways. The balance car has a body made of heavy cast-iron plates bolted together.

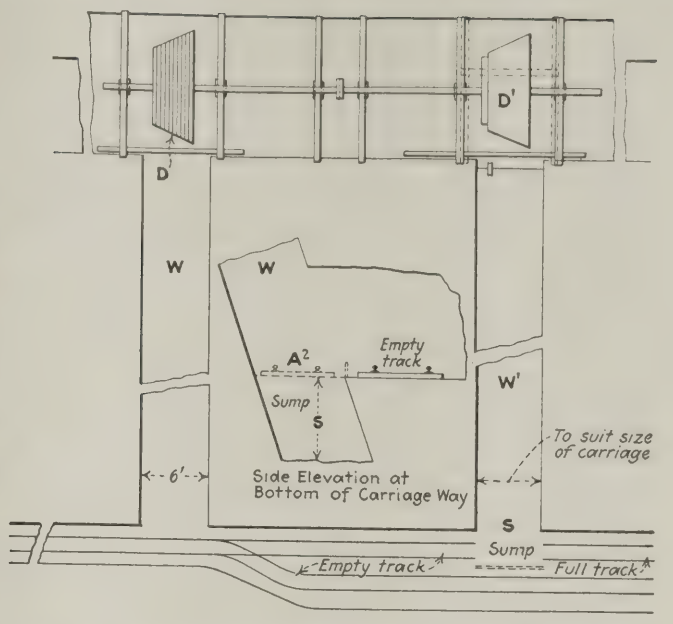

FIG. 25—ELEVATION SHOWING DRUMS AND PARTING

The illustrator has taken some license with the facts, the parting at the bottom being in plan and not in elevation like the rest of the drawing.

Belting to Revolutionize Mining Methods

PERHAPS because belting has been so tardy of introduction in American coal mines is why one has such large anticipations of what it will do when it is properly recognized. If the mines had to create the belting industry; if belts had to submit to the experimentation of men who did not understand the limitations of their own material there might be some fear, but long ago every other industry but coal mining learned the value of the belt. When the power houses were running sharp cinders over belts and the metal-mining industry was loading them with gritty material, the coal industry was wondering if perchance it would chafe a belt overmuch to take a load of soft coal. It seemed not to be realized that coal, being a light, not particularly abrasive material, should have led the way instead of following.

In the very nick of time comes a book on "Belt Conveyors and Belt Elevators," by Frederic V. Hetzel, who for thirteen years was chief engineer of one of the largest companies in the business and who for thirty years has been working on this class of machinery. Mr. Hetzel is practical and straightforward. He tells the story from within, not from without, giving the information of a man who has designed and erected belt conveyors. His book, containing 333 pages measuring 5¾x9 in., is published by John Wiley & Sons, of New York City.

We warn our readers that the book treats coal men with the attention they deserve as belt users but nevertheless it has several interesting references to coal and much that is of value to coal men where it is discussing the subject in general or the matter of the transportation of other material than coal in particular. In the

matter of power it says of a 48-in. belt between 387-ft. centers, sloped 18 deg., with a lift of 109 ft. and carrying 795 tons of run-of-mine coal per hour at 483 ft. per minute, a 150-hp. motor was used, but only 107 hp. was needed, as shown by electrical instruments. Roller bearings were used for the five-pulley idlers by which the belt was supported. A belt conveyor on similar roller-bearing idlers 48-in. wide on 405-ft. centers, sloped 19 deg., with a lift of 119 ft. and carrying 1,030 tons of run-of-mine coal per hour at 506 ft. per minute was equipped with a 150-hp. motor. Electrical instruments showed that it used 162 hp. A 42-in. belt conveyor with 600-ft. centers, sloped 18 deg., with a lift of 114 ft. and carrying 324 tons of run-of-mine coal per hour at 242 ft. per minute was equipped with a 100-hp. motor, but only 52 hp. was used. This also had roller bearings in five-pulley idlers.

The author says that with roller bearings the conveyor takes less power, the belt is subject to less tensile stress and requires less attention and lubricant, the idlers are less likely to stick tight and thus drag and injure the belt, and that the additional cost of the idlers is offset by a substantial reduction in the size of the motor needed and by a similar reduction in the number of plies in the belt.

Replacing Mine Haulage by Rubber Belt

An interesting quotation should now be made as to the possibilities of replacing mine cars by belting. "With a level belt conveyor one ton per hour can be conveyed a distance of 5,000 ft. over plain grease-lubricated idlers by one horsepower, or roughly 1 hp.-hour will convey one ton one mile. On the basis of power consumption alone a belt conveyor that carries one ton one mile in one hour is not so economical as a horse and cart, and for handling large quantities of material over long distances a train of cars drawn by a steam or electric locomotive will require much less power than a belt or a series of belts. To buy belts with their carrying idlers and driving machinery and build a structure to support the conveyor generally will cost more than to lay track and provide cars and motive power suited to the quantity of material to be handled.

"There are, however, conditions in which a long belt system may cost so much less for operating labor and attendance than will a car system that it will pay to install belt conveyors. For example, an important mining company had under consideration for several years a plan to carry 8,500 tons of coal per day from three inland mines to a shipping point on a river over four miles away. The choice lay between mine-car haulage with electric locomotives on the one hand and a belt-conveyor system on the other.

"From costs derived by the company from the operation of many haulage plants and several large belt conveyors, comparative estimates were made which showed: (1) The total cost of installation of the belt-conveyor system was about 25 per cent below that of the haulage system, and the annual charge for interest was correspondingly less. (2) The annual charge for depreciation for the conveyor system was about 15 per cent higher; this was based on an estimated life of three years for belts, five years for idlers, fifteen years (average) for other machinery and thirty years for steel and concrete work. (3) The estimated power cost for the belts was double that for the haulage. (4) The probable cost of labor and attendance for the belt system was about half the corresponding charge for the car system. This one item showed a difference of about $85,000 between the annual operating costs, and when balanced with the other items mentioned it was sufficient to show an estimated saving of over 3c. per ton of coal carried.

1 Hp.-Hr. to Transport 2½ Tons One Mile

"As a result of this comparison it was decided to install the belt system, and the work is now under construction (1922). The distance from the loading station in the mine to the bin at the river is 23,500 ft., and the total rise is about 200 ft. The conveyors, twenty in number, will be entirely underground and will be installed in existing mine passages which have been widened and straightened for the purpose. The idlers will be fitted with either roller or ball bearings. From power readings of similar conveyors installed at other mines it is expected that 1 hp.-hr. will convey 2½ tons one mile. This is more than twice the quantity which, according to the usual formulas, can be carried over ordinary idlers with grease as the lubricant of the bores of the pulleys."

The table at the head of the page is one of the many valuable tabulations this useful book contains.

It would serve little to list the subjects covered. Suffice it to say that the subject is exhaustively treated and the material up to date.

An Agreement Has Been Made between the U. S. Bureau of Mines and the Refractories Manufacturers' Association for the utilization of the laboratory car "Holmes" and crew for an investigation of fuel-burning equipment at refractories plants in the central district, with a view to determining wherein changes in equipment or practice will result in decreasing fuel consumption and increasing the output of fired ware. As planned at present, the crew will investigate the burning conditions at seven plants, including those manufacturing chrome, silica, magnesite, and fireclay wares. The burning conditions on round, square and rectangular-down draft kilns will be investigated.

Should High Pressure and Small Volumes Be Used in Underground Fire Fighting and How?

Pressure Can Be Regulated by Tanks with Floats, by Reducing Valves and by Throttles Placed in Hose Valves—½-In. Nozzle with 1½-In. 750-Lb. Test Rubber Hose Recommended—Peril in Mixing Impure with Pure Water

IN MANY coal mines fire fighting by direct methods is a subject of keen interest—in the anthracite region because large quantities of timber make the mines peculiarly subject to rapid and expensive conflagrations; in the Middle West and still more in the Rocky Mountains because of the extreme dryness of the timber and its tendency to dry rot.

Perhaps the problem must be attacked in coal mines in a different way from that in use in metal mines, where there is frequently more timber, but the remarks of B. F. Tillson, of the New Jersey Zinc Co., Franklin, N. J., entitled "Notes on the Installation of Fire-Fighting Equipment in Mines," at the recent meeting of the American Institute of Mining and Metallurgical Engineers will be found of interest.

It is noteworthy that they found their occasion in part at least in a bulletin of the U. S. Bureau of Mines published soon after, and as a result of experiments in connection with the Cherry Mine fire in Illinois. The Bureau at that time favored low pressure, and Mr. Tillson presented this paper in the hope that the bureau might make experiments of its own and subject that conclusion to further inquiry. Mr. Tillson remarks:

Not Only Extinguish Fire But Reduce Heat

"Although portable fire extinguishers are valuable for fires that are in an incipient stage, some medium that will dissipate a large quantity of heat is needed to fight a fire in mine timbers, because of the size to which it probably will have grown before discovery. Any method of sealing off or otherwise smothering such a fire with gases that will not support combustion, is often ineffective, for the residual heat will cause reignition when the area is opened, so that fresh air reaches the hot charred sticks of timber. It is therefore obvious that the most effective ways are to drown and cool the hot zone with water and to 'load out' the partly burned material and remove it from the mine.

"Either of these methods requires a direct attack of water upon the inflamed material; therefore every mine containing a large quantity of timber or other combustible should be as completely equipped with a fire-hydrant system as it is with compressed-air mains. Mine managers may at times object to the expenditure, especially if they have not suffered from mine fires and cannot realize the enormous loss of life and property resulting therefrom. The cost of such preventive measures against fires is small in proportion to the losses that may be incurred if a fire gains headway. Furthermore, the system of water pipes installed for fire protection can be used for other purposes, which will pay its carrying charges."

Mr. Tillson's reference to the other purposes for, or uses of, water pipes for fire service, as he himself explains in his article, has in view the need for water for use in wet drilling, but in coal mines the use would be rather the sprinkling of the mine to keep the dust moist. In regard to hand extinguishers he says:

"The old soda-acid extinguisher, or the more modern 'foam' types, are preferable. The former probably does not rely for its efficacy on the carbon dioxide generated but on the smothering and cooling effect of the water and the trajectory of stream that may be obtained because of the gas pressure developed. A foam having a tough film which will smother a fire, even on overhead surfaces, and which will have the added advantage of holding a greater quantity of cooling water against the burning surfaces would seem to be the best medium for fighting incipient fires in mine timbers.

"Fire patrols should examine a mine between the regular working shifts; one round should be made immediately after the last working shift and a second one within four hours. Time clocks should be provided to assure proper watchfulness. It is possible to get time clocks for servicing 100 or more stations. Ours are for sixty-four stations, which is as large a territory as one man can inspect. In a large mine the fire-patrol routes should also have several mine telephone stations.

"It is customary to have telephones at shaft landings, but these lose their value when access to the shaft is cut off. The interior telephones also save time in the patrolman's report of a mine fire and in the promptness with which help may be given him. It also will enable him to keep in touch with the hoisting engineer or some other centralized party, who would know, by the fire patrol's failure to report, that some accident had befallen him in making his rounds and thus could direct the other patrols or outside parties to render assistance.

"Some mines have avoided the expense of carrying

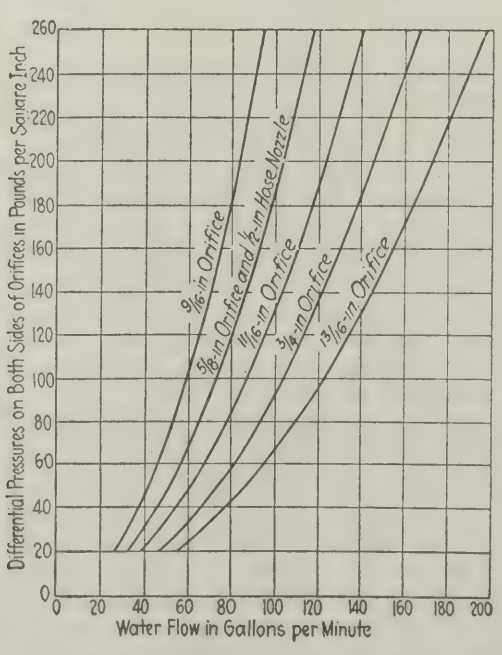

FIG. 1—DISCHARGE THROUGH ORIFICE AT VARIOUS PRESSURE DROPS

Loss of pressure for given flow of water in gallons per minute when a 1½-in. valve has its orifice reduced as noted on the various curves.

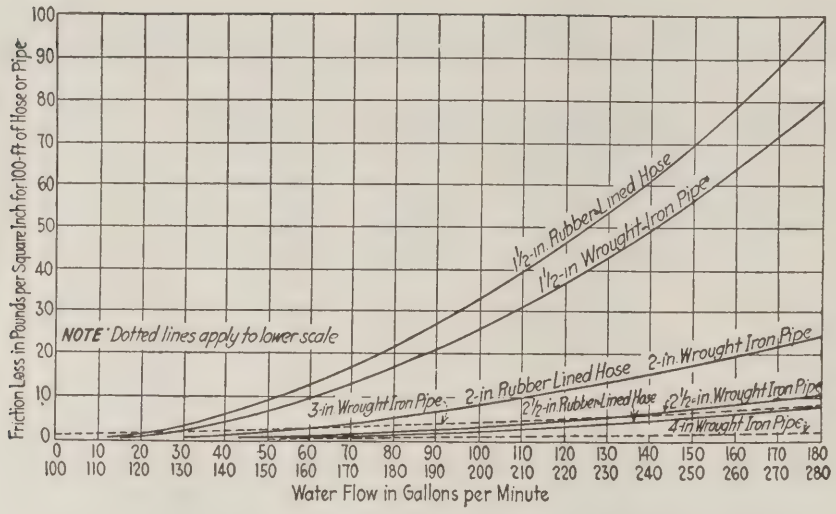

FIG. 2—FRICTION LOSS IN THE DISCHARGE OF WATER THROUGH RUBBER HOSE AND PIPE

The size of the pipe which is recommended for a rubber hose by the author of this paper is 1½-in., the distribution lines being of 3 or 4 in. diameter.

special fire-hydrant mains throughout the underground workings by arranging to turn water into the compressed-air lines in case of fire. There are several drawbacks to this plan. The compressed-air mains usually are smaller than is desirable for fire mains. The air-pipe joints and fittings possibly will be too weak to stand the hydraulic pressures that may be desirable."

Mr. Tillson discusses the use of compressed-air lines for an air supply in fire-fighting, a practice which coal men have never adopted and which most of them would look on with great disfavor. He regards this as a reason for not using compressed-air lines as a possible means of introducing water to a mine fire and then goes on to explain the shortcomings of the device of installing tanks at each level, for service in that level, with connections to the compressed-air lines which would make it possible to give the water a pressure it would not have hydraulically. He calls attention to the way in which such tanks might be depleted of their water and how meager would be the supply in any event. He adds:

Special Piping for Fire Fighting Only

"In view of the foregoing considerations it was decided to equip the Franklin Mine with a complete system of water piping. This system was connected with the mine-pump discharge column, which discharges into the bottom of a 25,000-gallon tank at the surface so that water will always be available even though the mine pumps should happen not to be running when the fire occurs. As insurance against an accident in the main shaft which might destroy the fire-fighting water supply, a second pipe is carried up a supply shaft and manway remote from the main shaft, where it can be joined to the town water supply and fire-hydrant system through the medium of a water tank.

"In planning the size and installation of underground fire-hydrant pipe lines the following factors must be considered: (1) The maximum volume of water effective from a single nozzle and hose line. (2) The minimum headroom clearances and the trajectory desired of the fire streams. (3) The maximum water pressures available. (4)) The number of streams it is desirable to play upon a fire at one level. (5) The greatest length of hose that should be relied on to carry the water from the pipe line to the fire. (6) The extent to which the hose will have to be transported, especially up confined ladderways. (7) The outcome of a decision as to whether advantage will be taken of the light weight and accessibility of the hose to rely upon the fire patrolman to make a prompt attack upon the fire while awaiting more extensive help.

"The New Jersey Zinc Co. has come to the conclusion that underground fire-fighting measures are widely different from those of fires in surface buildings. The exposed areas of the inflammable materials in a mine are not so large, the material is more concentrated, its height is not so great, nor is it exposed to the action of winds. On the other hand, the hot gases are likely to come into the faces of the fire fighters and the confinement of the workings will require the nozzle men to approach closer to the blaze than is customary at surface fires. Surface fire-fighting technique and equipment should not therefore be closely followed.

"A standard surface fire stream is based on a discharge of 250 gallons of water per minute, which will be passed by a 1¼-in. nozzle when the water at that point has a pressure of about 45 lb. per square inch. The smallest pump approved by the National Board of Fire Underwriters must discharge 500 gallons per minute or serve two such streams. It seems unnecessary to handle such volumes of water for the direct attack of mine fires and, in fact, it would appear undesirable to have such quantities draining through filled ground, undermining the timbers which the ground supports and unnecessarily taxing the mine drainage system.

Higher Pressures Give Flat Trajectories

"At the same time it seems desirable to have flatter and longer horizontal trajectories than are obtainable from the comparatively low pressures used with surface fire streams; flatter trajectories are easily obtained with the high static pressures obtainable from mine-pump columns, because of the depth of the mine workings below the surface. To reduce the volumes of water discharged the New Jersey Zinc Co. uses much smaller nozzles than those used in surface fire fighting for any given range of pressure, for if the nozzle is not made of sufficiently small cross-section, the water is ejected too much in the form of a spray instead of a fairly solid stream and will not carry well through the air.

"Some tests were made along these lines about ten years ago under the direction of George S. Rice, of the U. S. Bureau of Mines, and the results were published in Technical Paper No. 24, "Mine Fires," of which he is the author. However, these tests were not carried out under pressure anywhere near as high as we considered desirable and at which we have carried out a few experiments.

"Probably the chief reason why other tests were not made by the U. S. Bureau of Mines, which was cooperating with the Illinois Mining Commission and the National Fire Underwriters' Association, is its conclusion 'that one man cannot readily handle a 1½-in. hose with a ½- to ¾-in. cone nozzle in a narrow place, such as a mine entry or heading, when the water pressure exceeds 40 lb. per square inch and only with difficulty when the pressure is 50 lb. or over.'

"I take exception to this statement, which was repeated last fall in the report of the Standards Committee of Mine Fire-Fighting Equipment of the American Mining Congress. Our experience under the operating conditions below ground is that with either a ½- or a ⅝-in. nozzle and with a 2½-in. hose one man has no difficulty in controlling the nozzle reaction under pressures ranging from 150 to 186 lb. per square inch (the latter being the highest available under the conditions of our tests).

"I cannot but wonder whether the above adverse opinions were due to tests made in the handling of, say, 1¾-in. nozzles where the considerably greater volumes of water discharged naturally greatly augment the nozzle reactions. I would, therefore, strongly urge a renewed study of this subject by the U. S. Bureau of Mines and feel confident that its data and opinions will then be revised.

"We have adopted as a normal condition a ½-in. smooth-bore conical nozzle 12 in. long which will pass about 90 gallons of water per minute under what we consider to be a proper working pressure of 150 lb. per square inch. We have further adopted a 1½-in. rubber-lined rubber-covered fire hose with the intent that the maximum length of hose to serve a nozzle will be 200 ft., as it will then pass 90 gallons per minute with a pressure loss from friction of about 56 lb. per square inch.

"Under these operating conditions it would be possible to use a 'Siamese' connection on the end of 150 ft. of 1½-in. hose and connect two nozzles each with a 50-ft. length of hose and have a pressure of 90 lb. per square inch at each nozzle and pass 70 gallons per minute from each nozzle, or a total of 140 gallons per minute from the one hydrant connection if the pressure at the hydrant was 200 lb. per square inch.

Rosette Spray to Blanket Back Hot Gases

"It would seem that one of these nozzles might well be employed to form a rosette spray to blanket back the hot gases and form a fire-insulating shield which would permit the second nozzle crew to approach the flames more closely. If the headroom in the drift were 6 ft. in the clear, each of the above streams might be expected to strike a point in the roof about 55 ft. from the nozzle or to wet a point on the floor 100 to 110 ft. away.

"One of the factors to be decided is the method to be employed for regulating the hydrant pressures on the different levels and the maximum static pressures which will be permitted on the water lines. A reduction in these static presures may be obtained: (1) By breaking bulk through the installation of water tanks on different levels; (2) by the installation of pressure-reducing valves for the water supply at each level; (3) by the installation on each level of individually proportioned throttling orifices for the fire-hydrant outlets. The last method was chosen as the cheapest to install and to maintain.

"The first method requires one or more water tanks to serve each level (depending on its length); these must be located several levels above the one to be served, in order to give sufficient water head, and each tank must be of sufficient depth to afford a velocity head sufficient to assure the free passage of water from the tank to the pipe to supply the maximum water demand. Each tank must be equipped with float valves which will control its water supply. Unfortunately these valves are not easily kept in good operating condition. Furthermore, instead of a single pipe or two, the second being provided for safety, there is one or two for each level, and as the levels are close those for different levels overlap.

'The second method is that of using pressure-reducing valves. This requires a large investment for these rather expensive appliances. Moreover, they are not satisfactory for controlling static pressures and are likely to get out of order, especially when used with the dirty water from the mine. Their maintenance in working condition is sure to be expensive.

"As engineering literature appears to have no data covering the design of such pressure-reducing orifices, I have plotted, for the convenience of those who may wish to use such a pressure control, a number of curves showing the discharge ratings for a number of orifices of different sizes adapted to such an installation (see Fig. 1). The discharge of a ½-in. hose nozzle is practically the same as that of a ⅝-in. plate orifice. A chart also is given showing the pressure losses from the friction of various quantities of water flowing through 1½-, 2-, and 2½-in. rubber-lined hose and through wrought-iron pipes ranging from 1½ to 4 in. in diameter (see Fig. 2).

"Another chart shows the total pressure needed at the hydrant outlet for a ½-in. nozzle combined with 100 ft. and 200 ft., respectively, of 1½-in. rubber-lined hose,

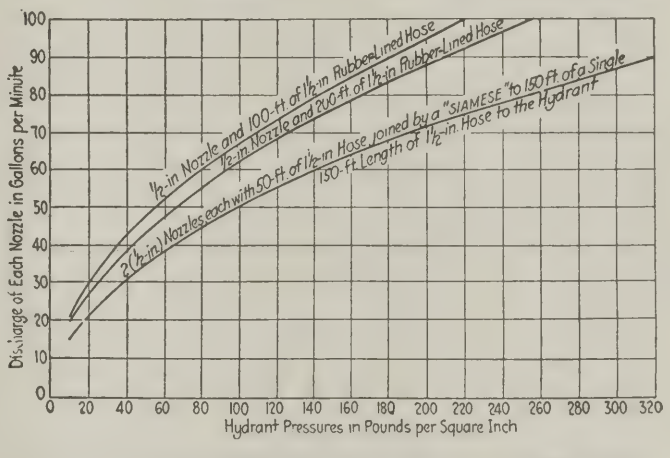

FIG. 3—TOTAL PRESSURE REQUIRED AT OUTLET SIDE OF HYDRANT ORIFICE

This allows for hose and nozzle friction and for a discharge of the stream indicated on the vertical co-ordinate on the left.

and also the pressure needed when two ½-in. nozzles (each with 50 ft. of 1½-in. hose) are 'Siamese-connected' to a single 1½-in. hose line 150 ft. long attached to one hydrant outlet (see Fig. 3).

"The fourth chart shows the approximate maximum distances that may be reached by fire streams from ½-in. nozzles operating at various pressures when the nozzle is elevated about 12-in. above the floor of a drift which is only 6 ft. high in the clear (see Fig. 4).

As the maximum static water pressure in the mine was about 500 lb. per square inch and as 3- and 4-in. lap-welded wrought-steel standard-weight pipes are rated to stand 1,000 lb. pressure per square inch and under tests have shown bursting pressures of 5,000 to 6,000 lb. per square inch, it seemed advisable to carry full pressures on the water lines and take advantage of the large drops in pressure then available to overcome friction losses and to install smaller pipes than otherwise would be required. It seemed that excellent results would thus be obtained in spite of the fact over 3,000 ft. of pipe was required on a level. It was not necessary, therefore, to use 4-in. pipe on levels more than 420 ft.

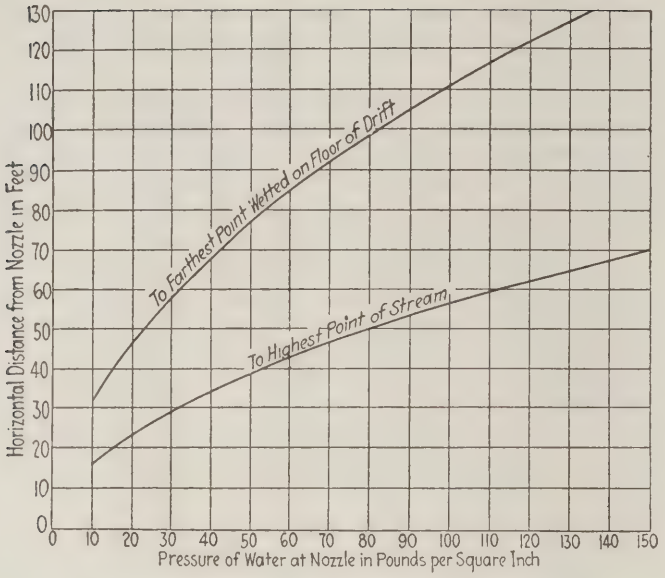

FIG. 4—TRAJECTORY OF HOSE STREAMS

This is the distance the stream will travel and the point at which it will reach its greatest height when escaping from ¾-in. nozzle elevated 12 in. above the ground with a maximum height of stream limited to 6 ft. above the floor of the drift.

below the surface, and some of the pipes used even on these levels are of 3-in. diameter.

"In general, screwed joints were provided, some flange joints, however, being introduced to make the installation of various bends easy. Malleable-iron standard refining-oil fittings are used from the surface to the 400-ft. level and extra-heavy malleable-iron fittings for the lower levels. These fittings were chosen in order to assure ample strength against mechanical strains which may be added to the water pressures. The lighter pipes are rated to withstand a water pressure of 200 lb. per square inch and the heavier are adapted for pressures up to 1,000 lb.

"The hose outlets are 4x4x2-in. and 3x3x2-in. tees with bushings to 1½-in. to which are attached by screwed nipples standard brass 1½-in. hose gate valves with male hose-coupling threads on one end. Brass caps attached by chains to the valve protect the hose-coupling threads when not in use. These valves are rated at 125-lb. steam pressure and 200-lb. water pressure, but our tests showed that they would stand 800 lb. per square inch hydraulic pressure without deformation or leakage. The hose coupling end was internally threaded with twenty-four threads per inch (as shown in Fig. 5) to permit the screwing in of the orifice plug which is used to control the outlet hydrant pressures. This threading also proved tight under a pressure of 800 lb. per square inch.

"These orifice plugs were installed as described on the outlet side of the hose valves so as to facilitate their removal should it be necessary to clean out any pieces of bark or wood fiber that might lodge behind and constrict them. This can be done easily and quickly after the hose gate valve is closed. As only open nozzles are permitted on the hose lines, the maximum pressures on the fire hoses will be the dynamic pressures permitted by the orifice dimensions. As there is a remote possibility, however, that a kinking of the hose might place it under a higher static pressure of possibly 500 lb. per square inch, the fire hose must stand 750 lb. per square inch bursting pressure for 5 minutes and some of the hose is built to stand a bursting pressure of 1,000 lb.

"We have been working for over six months with a number of hose companies testing special constructions of 1½-in. rubber-lined rubber-covered wrapped duck fire hose of different plies to get great strength and durability, maximum flexibility and portability with minimum weight, and have finally obtained hose that will meet the specifications that will be given later.

"This hose will be supported in 50-ft. lengths stretched out in V-boxes or launders suspended from the backs of the drifts at a slight gradient to insure natural drainage. Water will be passed through it once every six months to wash out the sulphur 'bloom' and stretch the rubber so as to keep it 'lively.' We are led to expect, under these conditions and in view of the darkness and humidity of the mine, that the hose will have a life of about fifteen years, without a depreciation in strength that will reduce the bursting pressure below 500 lb. per square inch.

"In general the hose valves are spaced from 150 to 250 ft. apart, except where the width of the mineral body makes it advisable to place them 50 to 60 ft. apart. The intent is to make the most remote points, even in top slices 50 ft. above a level, easily accessible with 200 ft. of hose. The levels on which the water lines and hydrants are located are about 50 ft. apart in elevation, so approximately 27,000 ft. of 3-in. pipe and 4,000 ft. of 4-in. pipe and about 160 hose valve outlets are required for this fire-protection system.

"Over 40,000 ft. of mine workings on the levels are thus given fire protection, to say nothing of the length of lateral drifts and parallel workings that likewise are protected. Cast-iron nozzles were adopted rather than brass because of their lower cost and because they would offer no temptation to anyone to steal and sell them to junk dealers. Thirty-five such nozzles and about 3,200 ft. of 1½-in. hose seem sufficient to supply complete fire protection.

Fire Lines Interconnected Between Levels

"In general, the fire lines on the levels have three or four vertically connecting pipe lines in ladderways, so that for any fire location the water is supplied in circuit from both sides of the fire area, thus normally reducing the friction losses by splitting the flow in any single pipe line on a level and also insuring a supply, even though a fall of ground should damage a fire line at some point on the level. Of course, enough gate valves are inserted in these mains to permit their necessary segregation under such emergency conditions.

"From 100 to 300 ft. of hose in 50-ft. lengths is allotted to a level, depending on its lengths, and by transportation up or down 50 ft. of ladderways the total quantity of hose on three levels—that is from 300 to 800 ft. hose—can readily be made available on any one level, as ten levels each have 100 ft. of hose, five levels 200 ft. each, and four levels 300 ft. each.

"The new (1922) National Fire Protection Association standard threads for 1½-in. hose couplings have been adopted and are recommended for general adoption by the mining profession, as they also have been adopted by the National Fire Protection Association, the National Board of Fire Underwriters and the Associated Factory Mutual Fire Insurance Companies.

"These male-coupling threads have the following specifications; nine threads per inch with a root diameter of 1.8376 in., a pitch diameter of 1.9138 in., and an outside diameter of 1.9900 in. The threads in the female coupling have a root diameter of 2.0150 in., a

pitch diameter of 1.9388 in., and an internal diameter of 1.8626 in.

"The mine should be equipped with several 'siamese' connections and with transformer couplings to permit under emergency conditions the coupling of the 1½-in. mine hose with the 2½ in. or other sizes of fire hoses used by the town fire departments in the communities adjacent to the mine.

"Although it may be possible to develop a four-ply hose which may approach the performance shown by the actual bursting test described in this paper, the five-ply hose described herewith is unusually strong for its weight and represents the best product we have tested. Its weight, uncoupled, is about 39½ lb. per 50-ft. length, and the pair of expansion-ring type brass couplings will add about 3 lb. more per 50-ft. length. When empty it will bend around about an arc of 8-in. radius without buckling on its inside periphery.

"It was built under a guarantee to stand for five minutes without bursting a test pressure of 800 lb. per square inch. The inside diameter is 1½ in. and the outside diameter 2 1/16 in. The five plies of fabric are cumulatively about 0.155 in. thick in a wall of the hose, so that the rubber lining and rubber cover are each about 1/16 in. thick.

"The rubber in the lining and cover is a high grade compound with good density and so prepared that it will prevent fungus growths from penetrating to the fabric. It should have a small quantity of an antiseptic, such as creosote, incorporated in it in order to insure this mildew-resisting property and should be designed to give a long life—say twenty years—with relatively small depreciation.

Hope Hose Will Last Fifteen Years In Mine

"We expect that a hose that will stand safely 750 lb. per square inch hydrostatic pressure when new will be in condition to stand at least 500 lb. pressure after having been kept in the mine fifteen years, as the exclusion of sunlight, the fairly uniform temperature of about 55 deg. F. and the uniform humidity underground in a mine are excellent conditions for its storage.

"The fabric used in this hose was a high-quality tire duck weighing 17½ oz. per square yard, made of Egyptian quality cotton fiber having a length of 1⅜ in., which is about the maximum obtainable in a staple fabric. The Scott machine used in testing the fabric had a capacity of about 400 lb., so the sample used was a strip 1 in. wide and 3 in. long clamped in the jaws of the machine and the jaws were separated at the rate of 20 in. per minute. When tested this way the duck shows 305 lb. as the strength of the warp and 335 lb. for the filler.

"Sufficient attention does not appear to have been given to the determination of a proper standard method of testing fire hose under pressure for acceptance or rejection. Underwriters' approved hose is commonly marked 'Tested at 300 lb. pressure' and during such tests the hose is under a pressure (varying from zero to 300 lb.) for a total time usually less than twenty seconds. Hose that stands this test may burst if the same pressure is maintained on it for a longer period. The hose manufacturers arbitrarily assume that hoses are suitable for a working pressure of about one-fifth of their instantaneous bursting pressures.

"Even when hoses are tested at certain pressures for five or ten minutes they are under stress too short a time for the test to be of practical value, as longer periods would be involved when in service. I would urge research in regard to the cumulative effect of such strains on the bursting strength of hose and a study of the lasting injury that may be done to the hose by longer testing periods under varying pressures, and would suggest that until such knowledge has been developed, one out of every five lengths of hose be taken at random and submitted to cumulative bursting pressures, each pressure stage being held for five minutes and arrangements for the hose to be under substantial pressures for forty to forty-five minutes in a manner somewhat similar to the performance test on the excellent 1½-in. hose to which reference has already been

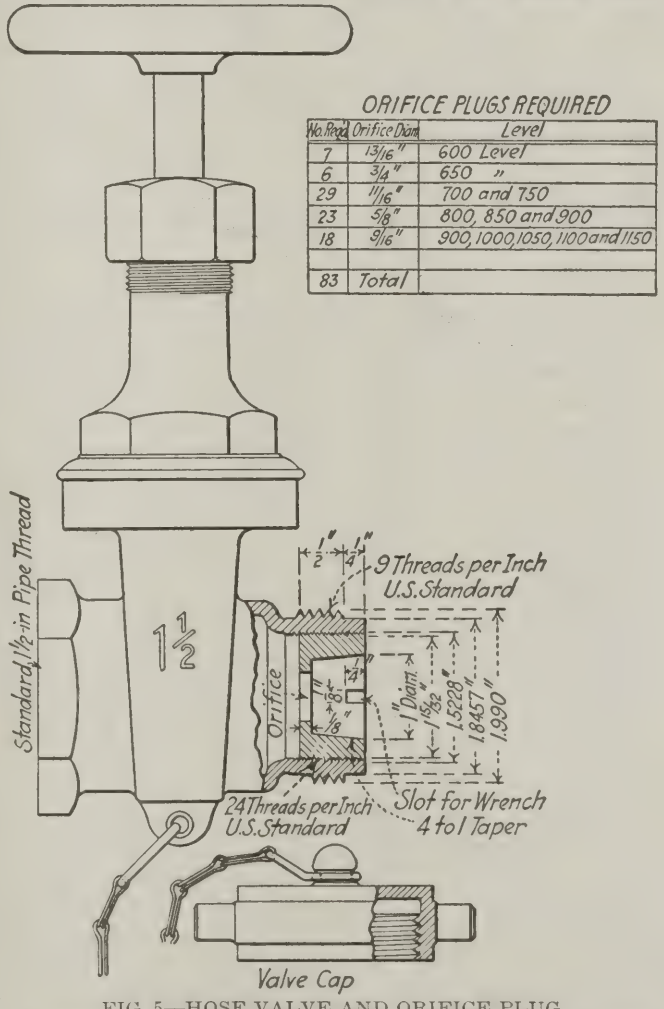

FIG. 5—HOSE VALVE AND ORIFICE PLUG

In order to lower the pressure of the moving stream of water a plug having an orifice which can be varied to suit the line pressure is inserted in the valve. This, of course, does not prevent the full line pressure being imposed on the rubber hose provided it should kink or clog. It prevents the man who is holding the hose from getting the "kick" that goes with fire fighting with hose which is subject to the full-line pressures. It also saves the hose from excessive strain provided it is kept from kinking, assuming, of course, that it does not clog and is not fitted with a spray nozzle.

made. As in this instance, the test can be made on a 3-ft. length, preferably cut from the end of the standard 50-ft. length, and the acceptance of the entire order of hose should be contingent on a perfect showing of all the 3-ft. samples.

"At this pressure the hose was bent in an arc of about 15-in. radius with no noticeable effect on it. The pressure was then raised to 1,025 lb. per square inch and the hose then burst, but not in the portion under tension during the bending test.

"The advisability or inadvisability of connecting, even as an emergency measure, a non-potable water system with a drinking water supply should be given far more serious consideration than has in general been accorded to it. The result of such connections may be an epidemic of typhoid fever or other water-borne disease. Such cross connections, however, are recommended by fire-insurance companies and fire-protection associations.

Helpful in Fire But Destructive to Health

"In general there are two reasons why for fire protection it is desirable to cross-connect the potable system designed for town fire fighting and domestic use with the non-potable system introduced into the industrial plant, whether for its protection against fire, for a supply of cooling water to its condensers, for providing water for its boilers or for other purposes. The first of these reasons is because increased fire protection will be afforded the plant by having a second source of supply for the sprinkler and fire-hydrant systems, and the second is because with this cross-connection the town dwellings and stores will be protected against the possibility of a general conflagration which might occur if the water supply in the town standpipe were to run short or if the mains feeding into, or leaving, the standpipe were damaged.

"In that case it is argued that it would be well to be able to introduce the non-potable plant water into the town system by means of the plant fire pumps. However, I am convinced that it would be far better to suffer whatever property loss might be involved by fire than to run the chance of infecting the public water supply. It is true that precautions might be taken for the disinfection and sterilization of the town water pipes subsequent to the passage of non-potable water. But this later act of grace would not prevent the probability that persons would drink some of the non-potable water during the period in which it was being used for fire fighting.

"The following methods I would condemn, though they have been considered acceptable practice in making cross-connections between non-potable and potable water systems: (1) The use of one or more check valves, or gate valves, or combinations of both in a cross-connecting pipe. (2) The use of a tee with an open outlet in the connecting pipe with a gate valve on each side of the open tee. Provision may be made to close the open outlet of the tee by a plug or blank flange, which can be applied when it is desired to use the connection, or a gate valve (normally open) may be mounted on the outlet of the tee. (3) A section of pipe may be removed between two gate valves in the connection and an emergency section of pipe, fitted with flanges or union couplings, of proper length to span this gap, may be kept available and ready for installation when an emergency demands the completion of such a connection.

"All these methods make possible the pollution of the potable supply when a connection is made, and therefore should be condemned. It is true that the conditions of the relative water pressures between the two sources of water supply may indicate that the only direction of flow may be from the potable to the non-potable system, but no confidence should be placed in such a state of affairs. Some years after this connection has been made, changes in the nature or operation of the plant pumping equipment may reverse these conditions and it is unlikely that the effect of such changes in regard to water pollution will be given any thought.

"Again, it will place an unfair burden upon responsible parties to resist the appeal that plant water be pumped into the town mains at some time when the town water supply is too low to meet a serious conflagration. The immediate urgent need of such a serious situation is likely to outweigh the seemingly more remote possibilities of pollution. If the connection is impossible the temptation for weakness in such a decision will be removed. Therefore, under no circumstances should it be possible to turn a non-potable water supply into a potable water system.

"A potable water supply, however, may be added to a non-potable water system, without danger of polluting the former, by placing a water tank between the two systems. This tank should have the inlet of the potable water supply above the maximum high-water level of the tank. Although this high-water level might seemingly be controlled by the location of overflow orifices or pipes, these might be choked by floating refuse or ice, so it would be safer to have the inlet pipe above the upper rim of the tank; even when so located a float valve may be placed to control the inflow of water. It is obvious that the interposition of a definite minimum air space between the two sources of water will furnish positive assurance against the pollution of the potable water supply from such a cross-connection."

Kingston Coal Co. Opens Community House

The Kingston Coal Co., which produces a sizeable tonnage of anthracite, annually, has opened a community house in Courtdale. The company donated the property some months ago, and the remodelling was completed in time to permit public inspection late in February. While the Kingston company was the prime mover in the community-house project, it has put control into the hands of the public.

The place is designed for the use of Courtdale citizens, and particularly children from the age of six years upward. The controlling organization is the Courtdale Community Club, which is open to everybody twelve years old or over, on the payment of 10c. a month dues, or $1 a year. The executive committee includes a member from every civic, patriotic and religious organization in the town, and every nationality is likewise represented. This committee controls expenditures absolutely.

Provision is made for club rooms for young men and young women. Children from 8 to 12 years have the use of the house Mondays and Thursdays from 5 p.m. to 7 p.m. They also may use it Saturday from 3 p.m. to 5 p.m., for annual membership dues of 25c. A little later there will be free kindergarten classes two days a week for children under eight years. Under the eye of F. E. Zerbey, general manager, the Kingston Coal Co. has maintained a kindergarten in Kingston for some years, and if the Courtdale House maintains the same good grade of work it will be doing a civic service of no small magnitude.

No provision for Sundays is made absolute, but the by-laws give the executive committee power, if they think wise, to open the house Sunday afternoons for reading or congregating, but with no games on that day.

Germany has given up the goose step for the sidestep.—*Washington Post.*

Developments in the Theory of Centrifugal Fans

"Equivalent Orifice" and "Orifice of Passage" Mere Befuddlement of Fan Problems—Analytic Methods of Obtaining Air Columns Generated by Fan—Relative Efficiencies of Single Fans and Fans in Series and in Parallel

By Henry Briggs*
Edinburgh, England

THE centrifugal fan, with its single moving part, is in one respect the simplest machine in or about the mine, but it has always been difficult to formulate a coherent theory respecting the principles of its action and design. Much that has been written on the subject is open to question, and some of it is definitely incorrect.

Yet a more perfect theory of the centrifugal fan would be of much assistance in practice, for it would help us greatly in understanding the reason for an undue wastage of energy and loss of efficiency or why it is that the machine acts so unexpectedly when the conditions under which it operates are apparently only slightly changed.

The writings of the French engineer Daniel Murgue have profoundly influenced the trend of thought in relation to fan ventilation, but the influence, in my opinion, has been out of all proportion to the real value of his work. Progress can be made only by relegating most of Murgue's notions and conclusions to the scrap heap.

Easier Conceptions Unmuddle Reasoning

The time has come for us to abandon the clumsy convention of the "equivalent orifice" as the means of evaluating the ventilating resistance of a mine and to seek for a simple and direct measure of the resistance of the ventilating circuit, equivalent to the electrical engineer's method of expressing the resistance of an electrical circuit in ohms.

Further, we must reject the "orifice of passage" of a fan, which, as it stands, is useless to the designer; it canot be determined by the process Murgue described because some fans produce a higher depression when passing air than when the inlet is closed. Unless we adopt a straightforward, direct unit by which to express fan resistance and unless we also devise an equally straightforward method of obtaining that resistance, progress in fan design must be retarded.

That many points of similarity exist between the flow of electricity in a conductor and the flow of air in a passageway is no new observation, but it was left to David Penman, principal of the Government School of Mines, Dhanbad, India, and an old student of mine, to make the most complete use of the analogy in one of the most suggestive papers on mine ventilation[1] that has been written in late years.

As Penman observes, the usually accepted relation between the ventilating pressure, p, required to urge the air round the mine and the volume, Q, of air passing per minute is:

$$p = RQ^2 \qquad (1)$$

Moreover, as R includes factors which remain constant so long as the mine resistances are unaltered, R evaluates those resistances. Equation (1), indeed, is the parallel of Ohm's law and differs from the latter only in involving the second power of the current instead of the first. As I elsewhere pointed out, it will be necessary to adopt a name for this unit of resistance before it can come to its full usefulness, and J. Parker has suggested the "atkinson" as that name. If p be measured in pounds per square foot and Q in hundreds of thousands of cubic feet per minute, the resistance of the mine in atkinsons is $p \div Q^2$. Here, then, we obtain a direct measure of mine resistance which is at once simpler in conception and more useful in application than the "equivalent orifice." The latter is an *inverse* measure of resistance connected to R by the relation:

$$\text{Equivalent orifice} = \frac{c}{\sqrt{R}}$$

where c is a coefficient determined by the units used.

In like fashion, we may express the pressure, p_0, needed to overcome the resistance, r, of the fan itself as:

$$p_0 = rQ^2 \qquad (2)$$

Therefore the total pressure, P, required to circulate the volume Q, against the resistance of both mine and fan is

$$P = p + p_0 = (R + r)Q^2 \qquad (3)$$

The most useful relation in connection with a fan is the manometric efficiency; it is the best criterion we possess of the suitability of its design.

The usual definition of this relation, F, is the ratio between the actual pressure (or depression) produced by a fan and the "theoretical" pressure (or depression), and by the latter is meant the pressure that would be produced were the fan perfect.

The hypothetical perfect fan is one of 100 per cent efficiency; it gives out as much energy as it receives, and it has no internal resistance; none of the pressure it creates being wasted in the fan and ajutages, the factor p_0 of equations (2) and (3) is zero; in other words, whereas the actual fan yields a pressure p, the

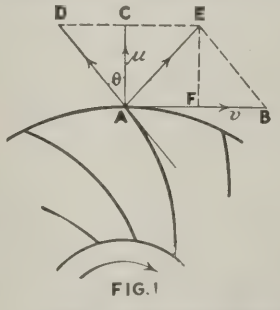

FIG. 1

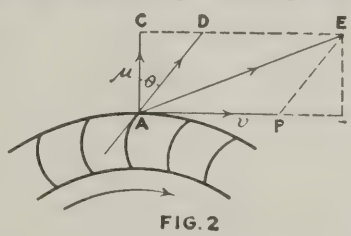

FIG. 2

FIGS. 1 AND 2—VELOCITY DIAGRAMS OF TWO FANS

The left-hand fan has the blades turned back and the right-hand is of the Sirocco type with the blades turned forward. AC is the radial component of the velocity of the air, or u. AD is the velocity of emission of the air relative to the peripheral speed of the tip of the blades. AB is the peripheral velocity of the fan. AC is the resultant of these velocities, which is less than the peripheral velocity when the blades are turned back as in Fig. 1 and greater than that velocity when the blades are turned forward as in Fig. 2.

*Professor of mining, Heriot-Watt College.

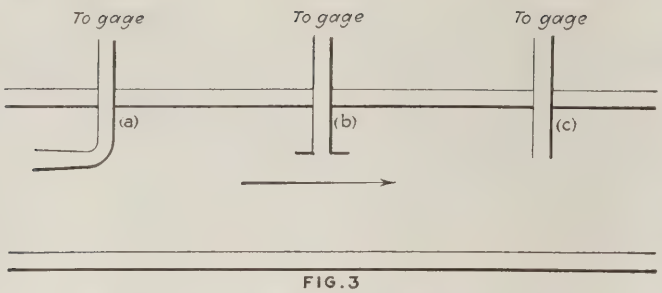

FIG. 3

FIG. 3—THREE WAYS OF SETTING A GAGE

The methods (b) and (c) both give faulty results. A zero or a negative indication may be obtained with a forcing fan and an excessively high reading with a suction fan. The gage should be placed as at (a) and should have limbs 3 or 4 ft. long. The glass should be clean. A little ox-gall in the water helps achieve this, but gasoline or benzine may be used instead of water.

perfect fan of the same dimensions and speed would be able to yield a pressure P when delivering the same volume of air. Thus we see that:

$$\text{Manometric efficiency} = F = \frac{p}{P} \qquad (4)$$

or, from equations (1) and (3)

$$F = \frac{R}{R + r} \qquad (5)$$

Hence the manometric efficiency allows us to determine the relation between the resistances in atkinsons of the mine and fan. For example, if a fan has a manometric efficiency of two-thirds (66.7 per cent), $r = \frac{R}{2}$, or the resistance of the fan is equal to half that of the mine. Again, if F is only 50 per cent, the mine and fan have equal resistances.

As it is obviously desirable that a fan resistance should be small in comparison with that of the mine, a high manometric efficiency is the best assurance we possess of the suitability of a fan to its task. In practice that efficiency, when rightly measured, usually lies between one-half and two-thirds; the fan resistance is therefore generally between 50 per cent and 100 per cent of the resistance of the mine. In such an expression of fan resistance, the losses due to imperfections of the casing and *évasé* chimney are included.

If the total pressure (or depression), termed P, in the above sections be multiplied by Q, the output of air, the product expresses the energy supplied to the fan to use or to squander. If Q is in hundreds of thousands of cubic feet per minute and P in pounds per square foot, that energy will obviously be in hundreds of thousands of foot-pounds per minute. As a matter of fact the quantity pQ is usefully employed in driving air through the workings and the remainder, or p_oQ, is wasted in the fan itself. Now the expression (equation 4) for the manometric efficiency can be rewritten:

$$F = \frac{pQ}{PQ}$$

or, if the numerator and denominator of the ratio be converted into horsepowers:

$$F = \frac{\text{Horsepower in the air}}{\text{Horsepower supplied to the fan}} \qquad (6)$$

The manometric efficiency is thus seen to conform to the accepted idea of an efficiency: It is a ratio of power given out to power put in. By the phrase "horsepower supplied to the fan" is meant the net power actually received by that machine without consideration of any external loss of power; it is the power that would be recorded by, say, a torsion dynamometer on the fan-shaft less the power lost by friction at the fan-bearings.

The "over-all efficiency" or "useful effect," E, of the fan plant is defined as:

$$E = \frac{\text{Horsepower in the air}}{\text{Electrical horsepower of driving motor or indicated horsepower of engine.}}$$

When both E and F have been correctly evaluated it is possible to draw up a useful energy balance-sheet, as in the following example:

A fan has a manometric efficiency of 60 per cent; the motor develops 80 electrical horsepower, the efficiency of the motor is 90 per cent, and the horsepower in the air is 40. The useful effect (from equation 7) is 50 per cent, and the brake horsepower of the motor, 72. From equation (6):

$$\text{Net hp. supplied to fan} = \frac{Hp.\ in\ air}{F} = \frac{40}{0.6} = 66.7$$

$$\text{Power lost in the drive} = 72 - 66.7 = 5.3 \text{ Hp.}$$

FAN PLANT: ENERGY BALANCE SHEET

Receipt	Hp.	*Expenditure*	Hp.
Electrical horsepower of motor	80	Loss in motor	8
		Loss in drive	5.3
		Loss in fan	26.7
		Horsepower in air	40
Total	80	Total	80

I have tried to emphasize the importance, in the practical sense, of the manometric efficiency; its value has never received proper recognition and has even been denied by some writers. Care must be taken in ascertaining it, and obviously the correct formulas must be used in the simple calculations involved. There is no doubt that these formulas are better understood by those dealing with centrifugal and turbine pumps than by those designing or running fans, and, as many books on mining contain serious blunders in this connection, it is perhaps advisable to look into the matter a little closely.

As most users of centrifugal fans are aware, the shape of the blades has a profound influence on the performance of the machine.

Figs. 1 and 2 show parts of the wheels of two fans, the former having vanes bent back from, and the latter bent forward toward the direction of motion. Both classes of machine are largely used. The angle at which the tips of the blades are bent is represented in each figure as θ, it being measured between a radius to the wheel and a tangent to the blade at its edge, A.

We will adopt the convention of giving θ a positive sign for a forward-trending vane (Fig. 2) and a negative sign for a back-turning vane (Fig. 1). The speed of the periphery of the wheel is in each instance v ft. per second, a velocity which is measured to scale along AB.

Let us consider the action of the perfect fan. It will deliver air in a uniform manner all round its circumference. If q cu.ft. be the air delivery per second, D ft. the diameter of the wheel, and B ft. its width at the periphery, the area of outflow round the wheel (neglecting the thickness of the blades) is πDB sq.ft. and the *radial* component of the velocity of the air on leaving the wheel must be u ft. per second, where

$$u = \frac{q}{\pi DB} \qquad (8)$$

AC (Figs. 1 and 2) represents this radial component in magnitude and direction.

The final velocity of delivery from the wheel must be the resultant of the velocity relative to the blade and of the velocity, v, of the wheel itself. AD represents,

in magnitude and direction, the velocity relative to the vane; that line is drawn as a tangent to the blade at A, and as the radial component is AC or u, its length must be correct. Taking the resultant of AD and AB, we obtain, in each diagram, the length AE as the velocity of emergence.

It will be observed that that velocity is less than the speed of the circumference when the blades bend backward and greater than that speed when they turn forward. In a fan like the Sirocco, in which the vanes point forward at about 45 deg., the speed of the air leaving the wheel exceeds the speed of the periphery of the wheel by about 80 per cent. In this we have the explanation of the high volumetric yield of fans of the type of Fig. 2.

Returning to the diagrams, the blades are responsible in each case for the creation, in the air, of the tangential component, AF, and, from the figures:

$$AF = v + u \tan \theta$$

(The sign becomes a minus for back-turning blades, for θ, under our convention, is then itself negative.)

If w lb. be the weight of a cubic foot of air, qw lb. are delivered per second; hence:

Tangential momentum gained per second

$$= \frac{qw}{g} (v + u \tan \theta);$$

and, as momentum gained (or destroyed) per second is itself the measure of the force creating (or destroying) the momentum, the last expression evaluates the tangential force in pounds, acting at the circumference, which has to be overcome by the source of power. As that force is moved a distance v ft. per second we obtain:

$$\text{Work done per second} = \frac{qw}{g}(v + u \tan \theta)v \text{ ft.-lb.}$$

Now in the fan of 100 per cent manometric efficiency under consideration all this work is used in delivering air against a pressure. A simple way of regarding that pressure is as the weight of a column of air H ft. high, and that is equivalent to a pressure of Hw lb. per square foot. The work done per second is therefore Hwq ft.-lb. Therefore

$$Hwq = \frac{qw}{g} (v^2 + vu \tan \theta)$$

or

$$H = \frac{v^2 + vu \tan \theta}{g} \qquad (9)$$

When the blades are radial at their tips, $\theta = 0$, and this important equation reduces to

$$H = \frac{v^2}{g} \qquad (10)$$

Again, when vanes point forward at 45 deg., $\tan \theta = 1$, and equation (9) becomes

$$H = \frac{v^2 + vu}{g};$$

when they point backward at 45 deg. it becomes

$$H = \frac{v^2 - vu}{g}.$$

Many of the older textbooks give equation (10) but lead the reader to infer that it applies to all kinds of fans. We have just seen that it relates only to fans having radially tipped blades and that the general form, equation (9), must be used in all other cases. The error involved by using equation (10) when equation (9) should be employed is often serious; it is always sufficient to render abortive any attempt to apply the manometric efficiency to any of the problems here discussed. In other works, and in papers by persons who should have known better but apparently do not, is to be found the expression $H = \frac{v^2}{2g}$

To illustrate the manner of applying equation (9) consider the case of a Sirocco fan 5 ft. in diameter and 6 ft. wide, running at 300 r.p.m. having vanes inclined forward at 45 deg. and delivering 90,000 cu.ft. of air at 2-in. water-gage. Here, as there are five revolutions per second, and as the circumference is 5π ft.,

$$v = 5 \times 5\pi = 78.6 \text{ ft. per sec.}$$

From equation (8):

$$u = \frac{\frac{90{,}000}{60}}{30\pi} = 15.9 \text{ ft. per sec.}$$

From equation (9):

$$H = \frac{v^2 + vu \tan 45}{g} = 230.5 \text{ ft.}$$

Taking 0.075 lb. as an average value for w, the weight of a cubic foot of fan-drift air, the equivalent pressure in pounds per square foot is 230.5 × 0.075, or 17.3.

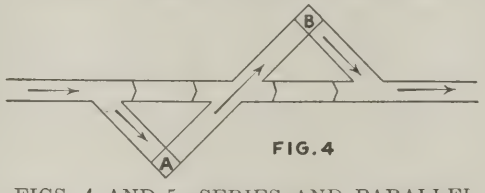

FIG. 4

FIG. 5

FIGS. 4 AND 5—SERIES AND PARALLEL FANS RESPECTIVELY

The author counsels, as have all other authorities, against series fans even where their manometric efficiency is high. It is better to run a single fan at a high speed. Where the manometric efficiency is low two fans deliver little more than one running at the same speed. Fans in parallel have a theoretical advantage and that is particularly evident where the manometric efficiency is quite low—that is, where the fan is based more in overcoming its own resistance than that of the mine. However, both fans in parallel must have precisely equal speed or one fan may draw air backward and through the other or at least take the most of the air.

The actual pressure realized, in the same units, is 5.2 × 2, or 10.4. Hence the manometric efficiency is $\frac{10.4}{17.3}$ or 60 per cent.

A large number of experiments on fans of various kinds have proved that when the mine resistance is kept constant the volume of air delivered per minute varies directly with the speed or if n be the number of revolutions per minute, and k a constant,

$$Q = kn \qquad (11)$$

A number of important conclusions follow from this simple relationship. For example, p varies as Q^2; therefore p varies as n^2, a result that is verified by experiment. Also power consumption varies as Q^3; hence power varies as n^3. Again, v varies as n and q as Q; therefore from equation (8), u varies as v, or the radial component of the air flowing from the wheel is proportional to the tangential velocity of the periphery of the wheel.

Let $\frac{u}{v} = c$; then equation (9) becomes

$$H = \frac{v^2}{g} (1 + c \tan \theta) \qquad (12)$$

As the terms in the brackets are constant so long as the mine resistance remains constant, and as H has been shown to be proportional to the total pressure, P, needed to circulate the air, again the combined resistance of fan and mine, we have P varies as v^2 and also as n^2, but, as just stated, p also is proportional to n^2. Hence the manometric efficiency $\left(\frac{p}{P}\right)$ is constant and

independent of the speed of the fan so long as the mine resistance is kept constant. As the manometric efficiency has been shown above to be equal to $\frac{R}{R+r}$, the satisfactory conclusion is reached that r, the resistance of the fan, also is independent of the speed of the fan.

Dozens of otherwise useful fan tests have been spoiled by taking the water-gage incorrectly. Most engineers now realize, however, that the end of the gage tube should be turned to face to windward as in Fig. 3 (*a*); otherwise the pressure or depression registered becomes affected by the velocity of the air, which in fan drifts is high. With either of the arrangements (*b*) or (*c*) it is quite possible, by placing

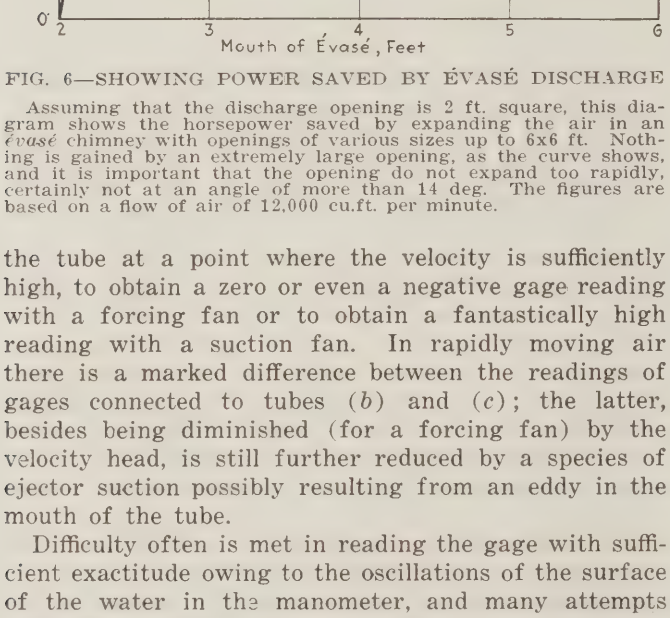

FIG. 6—SHOWING POWER SAVED BY ÉVASÉ DISCHARGE

Assuming that the discharge opening is 2 ft. square, this diagram shows the horsepower saved by expanding the air in an *évasé* chimney with openings of various sizes up to 6x6 ft. Nothing is gained by an extremely large opening, as the curve shows, and it is important that the opening do not expand too rapidly, certainly not at an angle of more than 14 deg. The figures are based on a flow of air of 12,000 cu.ft. per minute.

the tube at a point where the velocity is sufficiently high, to obtain a zero or even a negative gage reading with a forcing fan or to obtain a fantastically high reading with a suction fan. In rapidly moving air there is a marked difference between the readings of gages connected to tubes (*b*) and (*c*); the latter, besides being diminished (for a forcing fan) by the velocity head, is still further reduced by a species of ejector suction possibly resulting from an eddy in the mouth of the tube.

Difficulty often is met in reading the gage with sufficient exactitude owing to the oscillations of the surface of the water in the manometer, and many attempts have been made to damp the vibration by introducing a resistance at the bottom of the U-tube or elsewhere. It is inadvisable, however, to put in resistance at such a point; it becomes effectual only when the sensitiveness of the gage has been seriously diminished. After a number of trials of other methods I found that the best manner of steadying a gage is to make it large.

If the manometer be formed of a glass tube of 1-in. bore and having limbs 3 or 4 ft. long it is as sensitive as a small gage and the inertia of the water is sufficient to prevent rapid oscillations. It is important that the glass tube be thoroughly clean, or the meniscus does not form properly. A little ox gall in the water helps to keep the surfaces clean. A better way is to use gasoline or benzine instead of water; for these liquids, besides being lighter, are grease solvents and keep the tube clean.

The possibility of increasing the air volume by installing a second fan to run in series with the first has exercised the minds of many. When it has been tried the increase usually has been disappointing, though the adoption of fans underground working in series with a surface fan is a common expedient.[2]

Consider an arrangement such as that of Fig. 4, where there are two fans, A and B, which can be run either independently or in series. Let us assume that they are identical in every way. The resistance of the mine is R atkinsons, and that of either fan r atkinsons.

A test carried out with a single fan running enables the manometric efficiency to be ascertained, whence, by the aid of equation (5), the relation between R and r is determinable. When one fan only is running, the doors adjacent to the other being open, the total resistance is $(R + r)$ and from (3)

$$P_1 = (R + r)Q_1^2$$

Hence

Net power supplied to one fan

$$= P_1Q_1 = (R + r)Q_1^3 \qquad (13)$$

When the fans operate in series, delivering a volume Q_2, the total resistance of the system is $(R + 2r)$ and the total pressure required to overcome it is P_2, where: $P_2 = (R + 2r)Q_2^2$ or

Net power supplied to two fans in series

$$= P_2Q_2 = (R + 2r)Q_2^3 \qquad (14)$$

Let us inquire what happens when the power supplied to the fans in series is equal to the *sum* of the powers that would be supplied to the fans were they to run singly. From equations (13) and (14):

$$(R + 2r)Q_2^3 = 2(R + r)Q_1^3$$

$$\text{or } Q_2 = Q_1\sqrt[3]{\frac{2(R+r)}{R+2r}} \qquad (15)$$

It may be interesting to compare the results obtainable in this way when the fans have manometric efficiencies of 100, 67, and 50 per cent. For the perfect or 100 per cent efficient fan, $r = 0$; and, as has been shown above, for the 67 per cent fan, $r = \frac{R}{2}$, while for the 50 per cent fan, $r = R$. After applying equation (15) to each of these cases the results may be tabulated thus:

Manometric Efficiency	$\frac{r}{R}$	$\frac{Q_2}{Q_1}$
Per Cent		
100	0	1.26*
67	0.5	1.14
50	1	1.10

* This result was derived in the paper previously mentioned where a less rigorous method of analysis was followed. It is now seen to be correct only when the resistance of the fan is negligible, a condition never obtained in practice.

Had the same power been applied to one of the fans as has now been given to the two in series (and it could be so applied by increasing the speed of the fan by 26 per cent) the resulting increase in volume delivered by that fan running alone would have been 26 per cent. From the point of view of power consumption then it is clearly preferable to endeavor to increase the air discharge by speeding up a single fan rather than to place another fan in series with it; moreover, the lower the manometric efficiency the less effectual is the latter expedient.

In a few mines the circulation of air is altogether provided by means of underground fans operating in separate seams or in different sections of the same seam. Such fans work in parallel. In other cases there are two fans at the surface which can be arranged to operate either singly or in parallel. We will consider

[2] See "Uses for Underground Fans," by H. Briggs: *Coal Age*, vol. 8, 1915, p. 370.

the latter instance (see Fig. 5, where two exhausting fans are shown), and will assume the fans to be identical in every way, and to be running at the same speed.

When both are working each will deliver half the total volume passing, or $\frac{Q_2}{2}$, and the relation:

$$p_0 = r\left(\frac{Q_2}{2}\right)^2 = \frac{rQ_2^2}{4}$$

will hold true for the pressure needed to overcome the resistance of either machine. The usual formula: $p = RQ_2^2$ expresses the pressure required to overcome the mine resistance. Hence the total pressure to be exercised is $P_2 = \left(R + \frac{r}{4}\right) Q_2^2$ and the power to be applied $= P_2Q_2 = \left(R + \frac{r}{4}\right) Q_2^3$. The equivalent relation for a single fan is $(R + r)Q$. If these powers are made equal it is clear that a greater volume will be circulated when the fans are in parallel than when one is running alone. The benefit will be the greater the higher the resistance of the fans, and would in fact be zero if that resistance be negligibly small. An interesting exercise may in this case be made by comparing the power consumption when the quantity of air is kept the same, or when $Q_1 = Q_2$; that comparison is here set forth:

Manometric Efficiency	$\frac{r}{R}$	$\frac{\text{Power when both fans run}}{\text{Power when one runs}}$
100	0	1
67	0.5	0.75
50	1	0.62

To sum up: The conclusions as to fans in parallel differ radically from those relating to fans in series. The advantage of parallel running is small when the manometric efficiencies are high, but if those efficiencies are low considerable power is saved by that manner of operation. Experience shows that fans in parallel require careful speed regulation, and a ready means of speed adjustment thus becomes imperative. A small drop of speed in one causes the second to draw air in the reverse direction through it, with a corresponding increase of the load on the second fan.

The expanding, *évasé* or discharge duct of a fan, first introduced by Guibal, is, when correctly designed, an important means of improving efficiency. The function of a fan, like that of a battery on an electric circuit, is merely to produce a difference of pressure; any kinetic energy carried away by the air is so much energy wasted. The *évasé* effects a conversion from kinetic energy into pressure energy.

The chimneys used for suction fans may expand on opposite sides only, the other sides being parallel, or all four sides may be inclined outward. We shall here consider the latter form.

If the base or throat of an *évasé* be a ft. square, and the mouth b ft. square; if q cu.ft. per second be the volume of air passing up the chimney, and w lb. the weight of a cubic foot of air, then the air-velocity at the throat is $\frac{q}{a^2}$ and at the mouth $\frac{q}{b^2}$; hence, if the *évasé* is perfect in operation the saving in kinetic energy effected by the chimney

$$= \frac{qw}{2g}\left(\frac{q}{a^2}\right)^2 - \frac{qw}{2g}\left(\frac{q}{b^2}\right)^2$$

$$= \frac{q^3w}{2g}\left(\frac{1}{a^4} - \frac{1}{b^4}\right) \text{ ft.-lb. per sec.} \qquad (16)$$

In practice the term $\left(\frac{1}{b^4}\right)$ is so small in comparison with $\left(\frac{1}{a^4}\right)$ that it often may be neglected; for example, if $a = 2$, and $b = 4$ ft., the second term in the brackets is $\frac{1}{256}$ while the first is $\frac{1}{16}$; the error due to disregarding the former entirely would thus be only 6 per cent. We gather from equation (16) that the first part of the chimney is the most important. This fact is well shown by Fig. 6, which relates to an *évasé* 2 ft. square at the base and delivering 12,000 cu.ft. of air per minute ($q = 200$). If the air is allowed to escape direct from the 2 x 2-ft. opening, 1.06 hp. is lost in the form of kinetic energy; if a chimney expanding from 2 ft. square to 2 ft. 6 in. square were adopted a saving of 0.63 hp. would be effected. The saving would be 1.0 hp. if the chimney were enlarged until the mouth was 4 ft. square. Any further increase of size beyond that figure is of negligible service.

As a matter of fact it is highly doubtful whether a fan *évasé* ever effects more than 50 per cent of the saving indicated by equation (16). Many years ago Hennan and Gilbert carried out experiments on expanding chimneys of which two sides were parallel, and the others were capable of being set at different angles. Most of the efficiencies of *évasés* as determined by them lay between 40 and 50 per cent.

A duct of this character which expands too quickly is almost useless; the air stream does not fill it, choosing rather to follow one side or corner and producing a re-entrant current at the opposite side or corner. My experiments on air issuing from an orifice indicate that the stream expands at an angle of about 14 deg. The angle between opposite sides of a chimney square in section should be less than this, and one of 10 deg. is satisfactory. The further the inlet to the *évasé* is removed from the revolving blades the better the result.

Waste Fuels Are Grouped by the U. S. Bureau of Mines into two distinct classes—"Autocombustibles," which maintain their own combustion after ignition, and combustibles which will not burn without the addition of heat from an outside source or without mixture with an autocombustible. This second class may be termed for convenience "semicombustibles." With the improvement of furnaces for handling waste fuels, certain materials that were previously considered as semicombustible have joined the list of autocombustible fuels. Semicombustible fuels resist self-ignition mainly because they contain excessive moisture, ash and refuse, and have a physical structure that tends either to resist the passage of the draft or to form large openings in the fuel bed that admit much more air than is required for combustion; too little or too much air lowers the furnace temperature and the conditions that make for efficiency.

The Washington Society of Engineers and the Washington section of the American Society of Mechanical Engineers, in sending out an invitation to a joint meeting to be held this week, ran the following line of black-face capital letters on the invitation: "Order your coal early." Nothing pertaining to coal is to be discussed at the meeting. It apparently is an effort on the part of these societies to uphold the hands of the U. S. Coal Commission and of the Federal Fuel Distributor in the face of adverse criticism, in their advice to lay in stocks of coal at as early a time as possible.

Problems of Operating Men

Edited by James T. Beard

Featuring a Mine Explosion at Universal City, California

Filming a Mine Disaster—Chance to Instruct Public Regarding Mining Conditions—Picture Fails Because Mining Men Were Not Consulted

A MOVING picture director once told me that when he wanted advice on scenes involving mining operations he called on somebody at Los Angeles. That procedure might be all right for certain operations, such as those connected with metal mining, but for suggestions suitable to depict an explosion of gas at a coal mine our producer would have been wise if he had called on an engineer from, say the Pittsburgh district. Furthermore, to give the correct sequence of events in a scenario he should follow the story upon which the film is based.

I refer to a moving picture recently released by the Universal Pictures Corporation, and shown in New York and Pittsburgh, under the title of "The Flame of Life." A full-page ad. in *The Saturday Evening Post* of Feb. 5 drew my attention to the forthcoming production, and I lay in wait for it, as also did others. The picture is based on "That Lass o' Lowrie's," a novel by Frances Hodgson Burnett, and the locale of the scenes is at the coal-mining town of Riggan, Lancashire, England, in the seventies, when the early Davy safety lamps were used.

Opportunity to Educate Public in Mining Lost Because Film Portrays Unsafe Acts

This story affords a good chance to instruct the people in non-technical language, and at the same time to broadcast a lesson on the ventilation of gassy mines and the dangers from miners tampering with safety lamps and smoking underground. But the chance was lost. And to cap it all, after the explosion, at a dozen intervals of a minute or so there were great tongues of flame darting out of rooms into the entries and also out of the pit mouth. In spite of this flame shooting from the shaft, the heroine, with long hair, unprotected and nicely combed, clambered down to the bottom uninjured. There she pushed her way through an excited crowd of miners and eventually saved the "overman" (foreman), her lover, just as he was being swirled away by a rushing torrent of water (feet deep), presumably let loose by the explosion. Of course that was before the days of organized rescue crews or apparatus of any kind, and the heroine with others just battled against the afterdamp, although they were nearly overcome several times.

That's what the picture showed the public. But the real story briefly runs like this: This particular mine, and also near-by collieries, was gaseous. There had been explosions. Ventilation was effected by means of furnaces at the shaft bottoms, and at one mine, the return air, laden with methane, had been ignited at a furnace, with disastrous results. Derrick, a progressive overman at the mine of the story, had studied ventilating fans in Belgium, and wished to introduce them in place of the furnaces. But he encountered much opposition from miners and owners alike. Both were accustomed to a few casualties, which did not rouse anxiety unless there was a large loss of life.

Dangerous Practices of Miners Displayed as Prominent Features of Film

While Davy key-locked safety lamps were used, some of the men had keys, and lit their pipes from the flame of the lamp. Old Dan Lowrie was the worst offender, and hated the overman; but eventually he was caught and discharged. He tried to murder the overman, but was himself murdered on the surface, and not by a fall of roof underground, as shown in the picture. After repeated efforts to induce the owners to install fans the overman resigned, but on his last day, when underground, an explosion took place. A parson and Lowrie's daughter joined the rescuers and went below, and found the overman in a "gallery" (entry) which was perfectly dry. He recovered; the owners reinstated him, and adopted his plans for ventilation.

When will the moving pictures try to do the thing properly, A coal-mining engineer could have put them straight in a few minutes; so would the many mining films on file with the U. S. Bureau of Mines at its Pittsburgh Experiment Station.

Of course there were other scenes in this picture which were fairly well portrayed, but they concerned the sorting of the slate from the coal, and the everyday life of the people of Riggan, including the drinking bouts of Dan Lowrie, the inevitable fight, and a sentimental scene or two. And, by the way, the acting of the overman was pretty good.

Pittsburgh, Pa. M. W. von Bernewitz.

Relative Safety of Safety Lamps

Study intention of protective parts—Principle of wire gauze—Purpose of shield or bonnet—Precautions in removing gas and use of lamp.

WHEN reading the letter of W. H. Moore, regarding the relative safety of safety lamps, *Coal Age*, Jan. 25, p. 184, it seemed to me that the proper assembling and testing of a flame safety lamp are not the only important matters to which attention should be given in the use of the lamp. We should study carefully the intention and purpose of each protective part and use the lamp in a way that will not violate such purpose.

The account given by Mr. Moore, in reference to the supposed failure of the Wolf double-gauze safety lamp carried by the fireboss, at the time of the Wakesiah mine explosion, Nanaimo, B. C., leads me to think that

one or more of the vital principles of the lamp were violated by the fireboss and he suffered the penalty of his disregard of what makes a safety lamp safe.

In the first place, it is hardly necessary to refer to the oft repeated principle of the wire gauze that protects all openings in a safety lamp. It is well known that the wire must be kept cool so as to cool the hot or burning gas within the lamp, as the tiny streams of gas and air pass out through the mesh of the gauze. The temperature must be kept below the temperature of ignition of the gas in order to prevent the passage of flame through the gauze.

Lamp Unsafe in Strong Air Current

Besides keeping the gauze cool, there is another important item to be considered; namely, guarding the lamp against a strong air current traveling at a high velocity. The bonnet of the Wolf lamp, or the shield of the Davy is intended to protect the flame of the lamp in this regard. A high velocity of the air striking the lamp greatly assists the miniature streams of air and gas in passing through the mesh of the gauze.

Experiments have shown that an unbonneted Davy lamp is unsafe when exposed to a current having a velocity greater than 6 ft. per sec.; and the bonneted Wolf lamp is found likewise unsafe in a current of over 40 ft. per sec. Mr. Moore expresses the belief that, in the Wakesiah disaster the lamp had become heated by long use during seven hours prior to the explosion.

In addition to this heated condition of the lamp and with a full knowledge of the fact, the fireboss appears to have carried the lamp up the pitch against a current that Mr. Moore estimates as having a velocity of anything from 2,000 to 3,500 ft. per min., which would be considerably in advance of the safe limit of the Wolf lamp.

Constructive Principle of Lamp Violated

Assuming this summation is correct, who will deny that the constructive principles of the safety lamp were grossly violated and two lives were forfeited by reason of the act. Considering the plain intent of the wire-gauze chimney and the protecting bonnet with which the Wolf lamp was equipped, was not the safety value of the lamp depreciated when the fireboss carried his heated lamp against a strong current of air highly charged with gas?

A word, before closing, regarding the safe removal of a body of gas accumulated in a lodgment in the roof, as in this case. To attempt to remove such explosive gas at a high velocity is extremely dangerous. More time should be taken to enable the gas to be moved at a low velocity that would be safe.

A common error among mining men is to use any means that will drive out a body of gas in the quickest way possible. As in this instance, compressed air under high pressure is often employed, the air blast being directed against the gas at a very high velocity.

Brushing Gas a Dangerous Practice

Accumulated gas should always be moved by the ventilating current. Any method of brushing out the gas with a coat or a gunnysack, or blowing it out with compressed air involves many risks and should be prohibited by the law in every coal-mining state, as it is in many. The ventilating current should be made to sweep all cavities or lodgments in a manner that will prevent gas from accumulating in such places.

By way of summation, let me repeat the following precautions that should be taken in working a gassy seam:

Remove all gases with the ventilating current of the mine properly directed, and use no other means for that purpose. Allow no workmen in the mine, other than those employed in the work when removing a large body of gas. Gas should never be disturbed from its lodgment, however small the accumulation may be, without first notifying and withdrawing all men working on the return air current.

Test all flame safety lamps before they are taken into the mine, using for that purpose an explosive mixture, in a manner similar to that described in *Coal Age*, Dec. 28, p. 1042. Avoid any rapid movement of a safety lamp. When testing for gas never expose the lamp longer than to observe the first indication of a flame cap. Such indication is a sufficient warning to remove the lamp slowly and promptly from the mixture. Never expose a lamp to a high velocity of the current.

If an electric cap lamp is used, never break any connection or contact in order to cut out the light; but when making a test, the glare of the electric light should be prevented by screening the lamp.

Walsenburg, Colo. WILLIAM H. JAMES.

Bumping in Pillarwork

Instances of bumps in drawing back pillars—Bumping distinct from outbursts of gas in virgin coal—Flushing as a means of preventing bumps.

WITH much interest I read the letter of R. W. H., writing from Victoria, B. C., on the subject of outbursts of gas and bumps. In taking exception to the suggestion of a previous writer regarding the efficacy of the proposed stowing of waste in the worked-out portions of mines to prevent the occurrence of bumps, he asks if that writer had ever known of bumps occurring in worked-out areas.

If he will permit me, I can refer him to at least three instances where severe bumps occurred in mine areas or sections from which the pillars were being removed. Two such instances occurred in the State of Washington and one in the State of Wyoming. In neither case did the bumping occur in the live workings, which would seem to refute the idea he sets forth that bumps are always associated with the working of solid coal.

Severe Bumps Occur in Worked-Out Areas, Under Similar Conditions

In these three instances there is much similarity in respect to the surrounding conditions. In each case the bumping began in areas from which the pillar coal was being removed, under a depth ranging from 1,800 to 2,100 ft. of vertical cover, the roof being exceedingly strong while the floor was much weaker. The bumping was severe and resulted in the killing of three men and three locomotives were buried on the haulage roads.

In my opinion, there is an absolute distinction between outbursts of gas in virgin coal and bumps such as these occurring in areas from which the pillars are being removed. In the State of Washington, outbursts of gas have occurred in the solid coal of the advance workings. The same phenomenon occurred, also, in a mine on Vancouver Island and in several mines of the Crows Nest Pass district of British Columbia.

To my mind, the question of bumps in coal mining is an important one and should receive the serious consideration of mining men, both in the States and in Canada. It would be deeply interesting if the matter could be discussed in *Coal Age* and the experiences given of men who have studied the subject from an intimate association with such occurrences.

Facts and Data Regarding Occurrence of Bumps and Outbursts of Gas Wanted

Undoubtedly, the narration of incidents and citation of facts would throw much light on conditions in the mines that invite or make possible these occurrences. As far as practicable, measurements of the quantities of gas set free should be given, the condition of the mine described, and the possible relation of the bumping to the area worked out and the depth of cover and character of the roof and floor.

Personally, I am of the opinion that the proposed method of filling worked-out areas in mines, by the stowing of waste or by flushing, as the case may be, would be helpful in preventing the occurrence of bumps in areas from which pillars are to be removed.

However, the distance of movement of the roof, under the enormous pressure due to the weight of the overburden, can be comparatively small and still create a considerable disturbance within the area when the roof lets go. For this reason, the filling of the waste must be reasonably complete and the material well settled if good results are to be accomplished.

G. W. Evans,
Seattle, Wash. Consulting Coal-Mining Engineer.

Inquiries Of General Interest

Gobbing Slate in Rooms in Mines

Rooms Turned Right and Left Off Pair of Entries—Slate to Be Gobbed in Each Room —Manner of Gobbing Depends on Conditions

HAVING recently opened a mine on the room-and-pillar system and being desirous of securing the best possible economic results in respect to cost of operation and complete extraction of the coal, I take the liberty of asking the opinions of *Coal Age* and its practical readers regarding the most feasible and best method of gobbing the slate that must be taken down in the rooms.

In deciding this question we wish to have in mind and take into consideration the later extraction of the pillars, driving of breakthroughs, trackwork and timbering of roads. Realizing that each and all of these features have an important bearing on the economic working of a coal mine, we desire to start right.

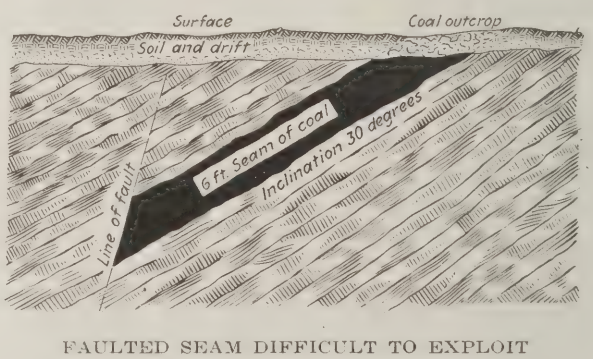
The question we would like to ask is, Which is the most practical side to gob the slate in these rooms? It would be interesting to have the various features of gobbing slate in rooms broadly discussed and hoping for this we shall watch these columns each week to learn something new.

A. L. Trimble,
Big Shoal, Ky. James Hatcher Coal Co.

The question of the most practicable method of gobbing slate, in driving rooms in mines, is so closely allied to many other features that unfortunately are omitted, it is only possible to reply in a very general way to this inquiry.

In the first place, conditions may make it advisable to drive double rooms, with track laid along each rib to facilitate the taking out of the wide pillars separating the rooms. In that case, the slate is gobbed in the center of the room between the tracks.

In driving single rooms, the track is generally laid along the straight rib and the slate is then gobbed on the opposite of the track, keeping it clear of the other rib so as not to hinder the drawing of that pillar. Under certain favorable conditions of roof and floor, it often becomes advisable to lay the track in the center of a wide room, gobbing the slate on one side of the track only, preferably the low side.



Locating the Coal Beyond a Fault

Bore holes in roof and floor to determine whether fault is normal or reverse—If normal, follow the greater angle the seam makes with the line of fault—If reverse, follow the lesser angle.

SINCE reading recent references to finding the coal beyond a fault, which have appeared in *Coal Age*, I am anxious to present a case that has puzzled us and which, as yet, we have not been able to solve. As shown in my sketch, we have a 6-ft. seam of coal outcropping on the surface and dipping at an angle of about 30 deg. We were driving a slope in this seam and had gotten down to a considerable depth when the coal was suddenly cut off by the slip or fault such as I have shown in my sketch. All efforts to find the coal beyond this point have, thus far, proved unavailing and I would like to ask how we should proceed with some assurance of success.

Joseph Lawrence.
Hazleton, Pa.

Judging from the sketch, which is here shown in the accompanying figure, assuming the fault to be normal,

FAULTED SEAM DIFFICULT TO EXPLOIT

it is a downthrow. This, however, must be determined before the work of finding the continuation of the seam can be prosecuted with any assurance of success. It may happen that the fault is a reverse fault, in which case it would be an upthrow.

In order to determine whether the fault is normal or reverse, a borehole must be sunk in the floor if the lesser angle between the fault line and the seam is at the roof; or a borehole must be put up in the roof if the lesser angle is at the floor. If the fault is a reverse,

one of these boreholes should find the coal if extended sufficiently far. If the fault is normal, the borehole will not reach the coal in either case.

Again, if the fault is normal, the continuation of the seam will be found by following the direction of the lesser angle. In the case of the reverse fault, it is necessary to follow the greater angle to find the continuation of the seam.

Examination Questions Answered

Examinations Under the Mine Act, Alberta, June, 1922

(*Selected Questions*)

QUESTION—*Give the relative advantages and disadvantages of the Wolf and Edison safety lamps. State under what conditions you would adopt the use of either of them. Give reasons.*

ANSWER—There is no Edison safety lamp. As has often been explained in *Coal Age*, the term "safety lamp" has reference to a gauze-protected lamp designed to admit air and gas to the combustion chamber, while the passage of flame to the outside air is prevented by the cooling effect of the wire gauze. The question probably refers to the Edison electric cap lamp, as compared with the Wolf flame safety lamp. Both of these types of lamp are in common use in mines.

The Wolf lamp is particularly useful in determining the percentage of gas present in mine air, by observing the effect of the gas on the flame of the lamp. This is one of the chief advantages of that lamp over the electric cap lamp. The Edison lamp possesses the advantage, however, of giving a bright light that greatly reduces the danger of accident in mine workings. While the electric lamp has the advantage of reducing to a minimum the possibility of the ignition of gas in the mine, the lamp affords no means of detecting the presence of gas, which is its chief disadvantage. The principal disadvantage of the Wolf lamp is its liability to extinction when being introduced into a body of gas. Owing to the highly inflammable oil burned in the lamp there is often produced what is called a "fuel cap," formed by the volatile oil and which is often mistaken for a gas cap when practically no gas is present.

The Wolf lamp should be adopted and used for the examination of any mine generating gas. In general, the Edison electric lamp gives better service as a working lamp, in mines generating gas or dust. The electric lamp is also far superior to the open torch where a mine generates no gas.

QUESTION—*If it requires 10 hp. to pass 20,000 cu.ft. of air per minute through a mine, the pressure being 5 lb. per sq.ft., how many horsepower will be required to pass 25,000 cu.ft. per min., under the same pressure?*

ANSWER—For a constant pressure, the horsepower required to circulate air in a mine varies with the circulation, which gives the proportion, calling the required horsepower x,

$$x : 10 :: 25{,}000 : 20{,}000 = 12.5 \text{ hp.}$$

QUESTION—*In a mine where shotfiring is carried on, it is noticed that at different times the air contains approximately 2 per cent of methane (CH_4), but this does not occur at regular intervals. The coal is of a very hard nature and it is essential that shotfiring be done. State what is the highest percentage of gas in the air in which you would allow shotfiring to be carried on and what steps you would take to see that your orders were being obeyed.*

ANSWER—From the statement of the question, it appears that shotfiring must be performed in the working of this mine, owing to the hardness of the coal. It also appears that gas is generated at irregular intervals to such an extent that the mine air is charged with 2 per cent of gas, which would be a dangerous condition in the working of a softer or more inflammable coal. However, in this mine, it is important that, not only should the morning examination be carefully made, but competent firebosses should be in charge throughout the day, each having charge of a limited section of the workings. No shots should be permitted to be fired without having first been examined by the fireboss and the place tested for gas. Preferably all shotholes drilled by the miners should be examined, charged and fired by competent shotlighters, after the men have gone home. Constant inspection should determine any violation of the rules and such should be promptly and suitably furnished.

QUESTION—*Describe in detail how you would place the shotholes in driving an entry 10 ft. wide and 8 ft. high; and state how you would arrange the work so that drilling and loading could take place simultaneously. State the number of men you would employ on each shift.*

ANSWER—Much will depend on the hardness of the coal, but ordinarily it may be assumed that the coal at the face of this 10-ft. heading should be sidecut and mined before any holes are drilled or fired. The placing of the shots will depend on the character of the seam in respect to any partings that would make it advisable to work out the coal in benches. Also, much will depend on the relative hardness of the several layers making up the full height of the seam.

However, assuming a uniform quality of the coal from the top to the bottom of the seam, good results will probably be obtained by starting the first row of holes about the center of the coal face. These holes should be given a slight inclination toward the sidecut. Perhaps two holes will be all that will be required to break down the coal in this half of the heading. Care must be taken not to drill the holes beyond the depth of the sidecut or mining.

With proper care, the coal on each side of this heading can be worked out alternately, by shooting first on one side and then on the other. It may not be necessary to sidecut the coal on more than one side of the heading. Instead, the holes for the extraction of the second half of the face may be drilled as close as convenient to the rib. Experience will determine the best position of the holes and the number required. In any case, care must be taken not to locate the charts in the upper hole too close to the roof, to avoid danger of shattering the roof slate. In this arrangement, mucking and loading out of the coal can proceed on one side of the heading, while drilling is in progress on the other side. In general, two or three men at the most should be employed on each shift.

Strike Fails in Central Pennsylvania

The second edition of the 1922 strike in central Pennsylvania, which the United Mine Workers of America called on Monday, April 2, is a failure, so far as the union is concerned, resulting in tying up for a time the mines of the Bird Coal Co., at Kelso, and the Cambria Fuel Co., both in Somerset County, but on the other hand resulting in a large number of union miners who have been out on strike at Windber for one year applying for their old places when they saw there was nothing doing there.

When the strikers at Windber found they were not being backed, many of the men sought their old places, it being apparent that there would be nothing doing this summer and as the strike was called only to force recognition of the union and the collection of the check-off, they had nothing to gain, as the open shop mines are paying union wages and working the eight-hour day.

Because of embargoes on roads controlling the northeastern market and a continued inadequate car supply, conditions are improving but little in the central Pennsylvania field. The car supply on the Pennsylvania lines is but little in advance of 25 per cent. Production in the district during the month of March was 77,518 cars, as compared with 69,297 cars in February.

Normally there are approximately 13,000 men employed in the Somerset field, affected by the strike call. Approximately 1,200 have been on strike for one year. J. C. Brydon, president of the Somerset Coal Operators' Association, states that these men are divided into three groups: First, those who are following their honest convictions; second, those who are satisfied to accept the relief and are not anxious to resume work, and third, those who refuse to work under any conditions as long as they can exist without working.

As a result of the dynamiting of a steel car on Sunday night, April 1, at Jenners No. 2, Somerset County, all bridges and tunnels on the Somerset and Cambria branch of the Baltimore & Ohio R.R. are being guarded. John Brophy, president of District No. 2, issued an order to union men against violence, urging them to respect the law and property. It has not been fully determined who placed the charge of dynamite under the car at Jenners.

A slight disturbance occurred at Carpenter Park, where the Cambria Fuel Co. operates. It is charged that a crowd of women and children threw pepper into the faces of two deputy sheriffs as they were on their way to the mines. Two women were slightly injured when the deputies fired several shots to scatter the mob. The injured were taken to Johnstown for treatment and later taken to their homes.

Judge John Berkey, hearing the cases in the Somerset County Court against twenty-five men and women charged with contempt of court, the charge growing out of the strike one year ago, discharged four women and five men. Fifteen women were sentenced and one youth was paroled. The fines ranged from $10 to $100. The fines were paid.

Failure to Reach Agreement in Seattle Keeps 2,000 Idle in Washington

Because no way has been found of breaking the deadlock that ended a wage conference held nearly a month ago, 2,000 union mine workers have drifted into a strike in the Roslyn-Cle Elum coal field. The wage conference held in Seattle between representatives of the Washington Coal Oprators' Association and state district officers of the United Mine Workers ended when the mine workers declined to accept a cut of $1.50 a day in the wages of the day men.

It is the contention of the union representatives that not more than 15 per cent of the mine workers in the Roslyn-Cle Elum field would be affected by the day wage cut, as virtually all the coal is mined under the contract system.

The contention of the employers is that the wages now paid in the Roslyn-Cle Elum field are higher than are paid in the non-union mines of western Washington and that a reduction of the wages down the line would be justified.

The strike affects approximately 2,000 men. Of this number approximately 1,700 are employed in the mines of Northwestern Improvement Co., a subsidiary of the Northern Pacific Ry. The others affected are on the properties of the Roslyn Fuel Co., the Independent Coal & Coke Co. and the Roslyn-Cascade Coal Co. Ten mines will be shut down.

A unionized coal mine at Tono in Lewis County, western Washington, operated by a subsidiary of the Union Pacific R.R., also is involved. This mine employes about 200 men.

Martin J. Flyzik, state district president of the United Mine Workers, and John H. Wallace, commissioner of the Washington Coal Operators' Association, are now in the East to confer with officers of President Harding's fact-finding commission over the Washington situation.

1,000 Kanawha Miners Strike

Approximately 1,000 miners went on strike April 3 at the mines of the Oakland Coal Co., Crescent Coal Co., E. L. Michie and Edwin Marmet, in the Montgomery district of the Kanawha field, according to an announcement by D. C. Kennedy, secretary of the Kanawha Coal Operators' Association.

The strike came at the termination of the individual agreements between the miners and operators, Mr. Kennedy said. A delegation of the striking miners reported to headquarters of District 17, United Mine Workers, their action in refusing to go to work when the agreements expired. E. L. Michie was a member of the operators' scale committee and signed the scale on which the individual contracts were negotiated, Mr. Kennedy said.

Western Kentucky Strike Is Softening

The first sign of disruption has appeared in the ranks of the coal operators of Hopkins, Christian and Webster counties in western Kentucky who refused to sign a one-year contract with the miners' union, thereby drawing a strike on April 1. The Circle City Coal Co., at Nebo, is reported to have signed the one-year contract on the same basis as the rest of the unionized districts of the country. The company's mine employs about seventy-five men. Although there were reports that some of the other forty mines involved in the strike were to be reopened on an open-shop basis, nothing of the sort has occurred. All the rest of western Kentucky is working unaffected since the West Kentucky Coal Operators' Association has already signed with the union for one year.

Contract Not Renewed, Alabama Men Out

About half of the miners at the Beltona mine of the American Fuel Co., near Warrior, Jefferson County, Ala., are reported on strike as a result of refusal of officials of the company to renew the union contract which expired April 1. This was one of the few operations in the Alabama field working under a contract with the United Mine Workers, and it is understood that the management of the company will decline to negotiate another contract with the union. The daily production of the mine is about 1,000 tons.

Union Granted Appeal from McClintic Injunction; Argument May 2

Following arguments made on March 31, the United States Circuit Court of Appeals at Richmond on April 2 granted an appeal to the United Mine Workers of America from the injunction of Judge George W. McClintic, of the United States District Court for the Southern district of West Virginia, prohibiting the use for unionization of non-union mines of funds collected through the check-off from certain coal companies operating on a union basis in the Kanawha field. The appeal operates as a suspension of the injunction of Judge McClintic until a final determination of the case or until further order of the court. The case will come up for final argument at Richmond on May 2. Appearing for the United Mine Workers at the hearing on March 31 was William A. Glasgow, Jr., of Philadelphia, and for the non-union operators were S. B. Avis, A. M. Belcher and E. L. Greever.

Bituminous Coal Stocks Fall 2,000,000 Tons in Month; 22 Days' Supply on Hand March 1

Commercial consumers had in storage approximately 36,000,000 tons of soft coal on March 1, 1923, according to a survey undertaken by the Bureau of the Census and the Geological Survey under authority of the Federal Fuel Distributor. The steady upward trend in stocks since the end of the miners' strike early in September was interrupted in February and the reserves on hand decreased 2,000,000 tons. Stocks on March 1, 1923, were about midway between those on March 1, 1920, when the reserve supply was close to the lowest recorded, and those on March 1, 1922, when a very heavy tonnage had been stored in anticipation of a general strike of union miners.

Measured in tons, stocks decreased 5.3 per cent between Feb. 1 and March 1. Measured in terms of days' supply, the decrease was 8.3 per cent. The larger decrease in days' supply was due to the fact that the rate of consumption increased in February.

Assuming that the stocks were evenly divided, the supply on March 1 was sufficient to last 22 days, against 24 days on Feb. 1. When stocks dropped to 20,000,000 tons on June 1, 1920, the market was seriously disturbed, and on Sept. 1, 1922, when the supply on hand was 22,000,000 tons, there were urgent appeals for coal.

Stocks of anthracite in the yards of retail dealers on March 1 were 40 per cent less than on Feb. 1. The quantity of anthracite on the Lake docks was less than a fifth of what it was a month ago.

TABLE I—ESTIMATED TOTAL COMMERCIAL STOCKS OF BITUMINOUS COAL IN THE UNITED STATES *a*

(In net tons)

Oct. 1, 1916	27,000,000	Aug.	1, 1921	41,100,000
Oct. 1, 1917	28,100,000	Nov.	1, 1921	48,500,000
July 15, 1918	39,700,000	Jan.	1, 1922	48,000,000*b*
Oct. 1, 1918	59,000,000	March	1, 1922	52,500,000*b*
Day of the armistice	63,000,000	April	1, 1922 at least	63,000,000*bc*
Jan. 1, 1919	57,900,000	Sept.	1, 1922	22,000,000*b*
April 1, 1919	40,400,000	Oct.	1, 1922	26,000,000*b*
March 1, 1920	24,000,000	Nov.	1, 1922	32,000,000*b*
June 1, 1920	20,000,000	Jan.	1, 1923	36,000,000*b*
Jan. 1, 1921	45,800,000	Feb.	1, 1923	38,000,000*b*
April 1, 1921	39,500,000	March	1, 1923	36,000,000*b*

(*a*) The figures for 1918 in this table are based upon an actual count. Beginning April 1, 1919, the figures are estimates based upon reports from a selected list of 5,000 consumers whose stocks in 1918 bore a known relation to the known total stocks. (*b*) Subject to revision. (*c*) No canvass of consumers was made on this date. The total stock was estimated from the stock on March 1, ascertained by questionnaire.

The total quantity of soft coal in the hands of commercial consumers on March 1, 1923, was between 34,000,000 and 38,000,000 net tons, probably 36,000,000 tons. In this estimate no account is taken of coal in the cellars of householders, concerning which no statistics are available, nor steamship fuel, nor coal on the Lake docks, which is classed as coal in transit.

From Table I and Fig. 1, which presents the same data graphically, it is seen that coal was withdrawn from storage during February. Observers who have been watching the downward trend in production will not be surprised at the decrease of 2,000,000 tons in stocks. Indeed, the actual draft on available coal was greater than is indicated by the decline in consumers' stocks, as there was an appreciable decrease in the tonnage in transit. There is a considerable lag between the production of coal and its arrival at points of consumption, and the quantity to be accounted for on March 1 was that mined from Jan. 15 to Feb. 15, which was approximately 45,600,000 tons. It is estimated that consumption, including foreign bunker coal, plus exports, during February was approximately 47,600,000 net tons, or at the rate of about 1,700,000 tons per day.

The average stocks for all consumers on March 1 were sufficient to last 22 days at the rate of consumption in February. At the rate of consumption in January the stocks on Feb. 1 would have lasted 24 days. These statistics, shown by classes of consumers in Fig. 2 and in the table below, are based upon reports of tons on hand and actual consumption received from about 5,000 consumers, so selected as to be fairly representative of all commercial consumers. The rate of consumption used in calculating the days' supply on March 1, 1923, was the quantity actually consumed in February. The days' supply on March 1, 1922, was calculated by using the rate of consumption in January and February, 1922.

TABLE II—DAYS' SUPPLY OF BITUMINOUS COAL IN HANDS OF VARIOUS CLASSES OF CONSUMERS IN THE UNITED STATES, JAN. 1, 1919, TO MARCH 1, 1923 *a*

(Figures represent number of days supply would last at current rate of consumption at time of stock taking.)

	Jan. 1, 1919	Mar. 1, 1920	Jan. 1, 1921	Apr. 1, 1921	Jan. 1, 1922	Mar. 1, 1922	Sept. 1, 1922	Oct. 1, 1922	Nov. 1, 1922	Jan. 1, 1923	Feb. 1, 1923	Mar. 1, 1923 *b*
Byproduct coke plants	32	15	29	28	42	39	11	14	18	19	20	19

Railroads	32	11	23	24	35	42	13	15	13	16	18	16
Total bituminous	42	18	39	36	41	43	17*c*	21*c*	23*c*	26*c*	24*c*	22*c*

(*a*) The figures in this table are estimates based on incomplete data. (*b*) See text for rate of consumption at which these figures were calculated. (*c*) Subject to revision.

Fig. 3 shows graphically the variation in stocks in each state. The map shows the days' supply held at general industrial establishments, excluding steel and byproduct coke plants. This is the largest group of consumers and the one that shows best the distribution of stocks. Changes in activity in this group are quickly reflected in the coal market, and likewise changes in the coal market soon become apparent in the reserve stocks of industrials.

Taking the country as a whole, the stocks held by general industrials were sufficient to last 34 days. This was a decrease of 2 days from the supply on Feb. 1, 1923. Comparison with corresponding dates in preceding years shows that the supply would have lasted 7 days longer than the stocks on March 1, 1920, and 22 days less time than those on March 1, 1922. In 23 states the supply on hand was sufficient for less than 30 days. In New England and the Atlantic Coast States, with the exception of New Hampshire, Maryland and North Carolina, the supply would have lasted more than 30 but less than 60 days.

It is evident from the quantity of bituminous coal delivered by the retailers that the deficit in the supply of anthracite has not been entirely made up and that the gap between production and requirements of anthracite is largely being filled with bituminous coal. For this reason

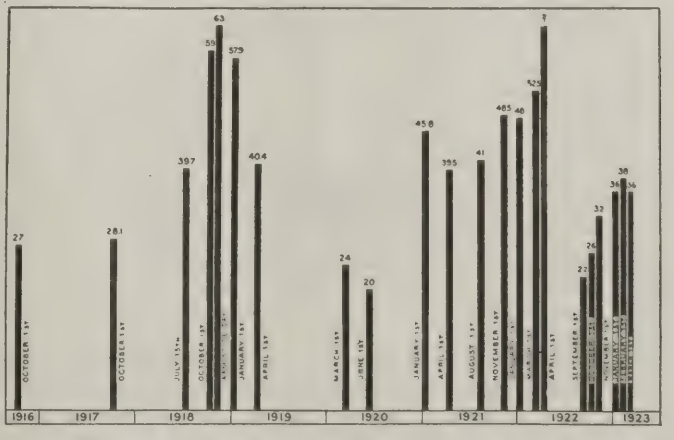

FIG. 1—TOTAL COMMERCIAL STOCKS OF BITUMINOUS COAL, OCT. 1, 1916, TO MARCH 1, 1923

Figures represent million net tons and include coal in hands of railroads, industrial consumers, public utilities and retail dealers. Coal for steamship fuel, on Lake docks and in transit is not included. Figures for 1922 and 1923 are subject to revision.

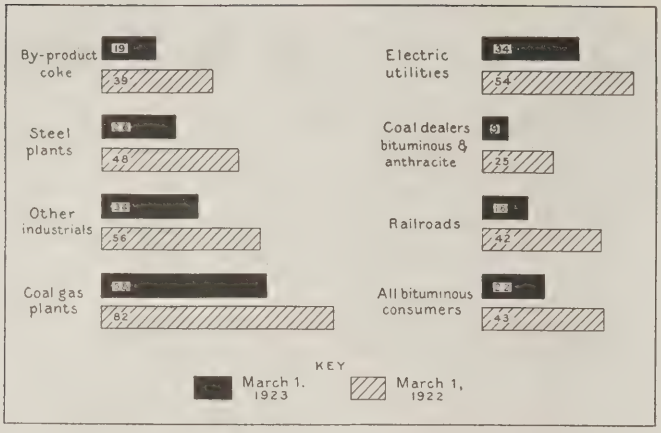

FIG. 2—DAYS' SUPPLY HELD BY DIFFERENT CLASSES OF CONSUMERS ON MARCH 1, 1923, AND MARCH 1, 1922

At the rate soft coal was burned in February, 1923, the stocks on hand March 1 were sufficient to last 22 days. The stocks on March 1, 1922, when heavy reserves had been accumulated in anticipation of a miners' strike, were sufficient to last 43 days at the rate of consumption in January and February, 1922. The stocks on March 1 were sufficient for 2 days less time than those on hand Feb. 1, 1923.

it is desirable to consider bituminous and anthracite combined in the territory where hard coal is burned.

Outside the anthracite territory the situation was as follows: Stocks decreased in every state except Arkansas, Louisiana and Wyoming, where there was no change. Over the country as a whole retailers' stocks of bituminous coal decreased nearly 23 per cent. Increases occurred only in New Hampshire, Massachusetts and Virginia.

The quantity of unbilled coal at the mines increased from 165,000 tons on Feb. 1 to 183,000 tons on March 1, an insignificant part of the available supply. The tonnage at junction points and terminals awaiting reconsignment decreased from 65,000 to 43,000 tons.

Reports from an incomplete list of producers equipped to store show that nearly 950,000 tons were in storage on March 1 at the mines, against 860,000 tons held by the same producers on Feb. 1. The number of producers who store is small, but the quantity in storage may at times be considerable.

Stocks of byproduct coke decreased 40 per cent in February and the quantity on hand on March 1 was but 87,000 tons. This was barely one-tenth the stocks on March 1, 1922, when the reserve was heaviest.

Severe winter weather maintained the demand for anthracite at a high level throughout February, and retailers' deliveries so far exceeded receipts that stocks dropped

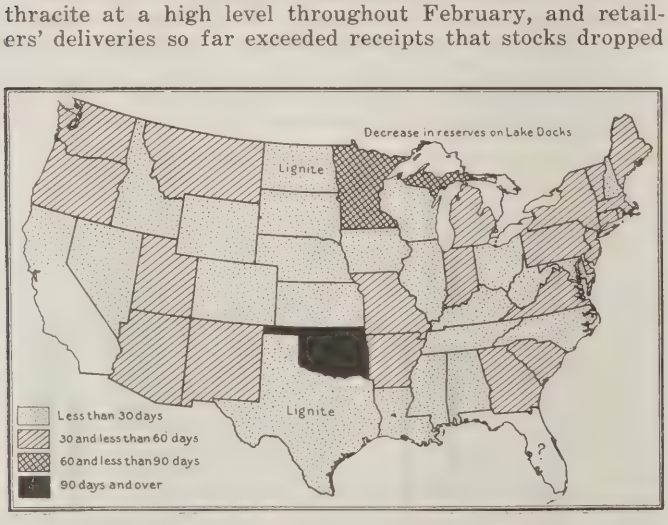

FIG. 3—DAYS' SUPPLY OF SOFT COAL ON HAND AT INDUSTRIAL PLANTS ON MARCH 1, 1923

At the rate of consumption that prevailed in February, 1923, reserve stocks at industrial plants other than steel and byproduct coal would last on the average 34 days. The map shows how the supply varied from state to state. Note the absence of the darker shading which would indicate heavy stocks. Any change in business activity after March 1 which affected coal consumption would be reflected in the days' supply. Based on reports from 2,260 plants.

TABLE III—ANTHRACITE IN YARDS OF A SELECTED LIST OF RETAIL COAL DEALERS *a*

Date	Net Tons	Days' Supply *b*	Date	Net Tons	Days' Supply *b*
1919–Jan. 1	904,712	36	1922–Jan. 1	1,336,953	44
April 1	785,840	31	March 1	1,093,734	28
1920–March 1	727,727	21	1923–Jan. 1	403,605	11
June 1	515,149	15	Feb. 1	356,121	8
1921–Jan. 1	685,615	24	March 1	215,063	6
April 1	1,140,757	36			

(*a*) Based on statements from 368 identical dealers who reported on each date
b) Calculated at current rate of delivery to consumers, which varies.

sharply. The supply in the yards of 368 retail dealers on March 1 was 215,063 net tons, a decrease during February of 141,058 tons, or 40 per cent. Stocks were 80 per cent less than on March 1, 1922, 81 per cent less than on April 1, 1921, and 70 per cent less than on March 1, 1920. Retailers' stocks of anthracite on March 1, 1923, at the rate of delivery in February, would have lasted an average of 6 days, whereas the supply on March 1, 1922, was sufficient for 28 days, and on March 1, 1920, for 21 days.

Anthracite was mined at a high rate in March, but as cold, stormy weather prevailed in most sections of the anthracite-consuming territory during a large part of the month, it does not seem likely that reserves have increased greatly.

Reports from retailers in the anthracite-consuming territory indicate an increased demand for bituminous coal as a

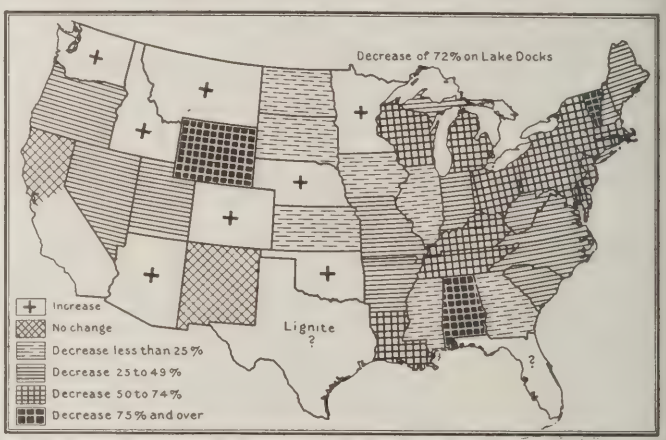

FIG. 4—HOW RETAILERS' STOCKS OF ALL COAL—ANTHRACITE AND BITUMINOUS—ON MARCH 1, 1923, COMPARED WITH THOSE ON MARCH 1, 1922

Stocks of bituminous coal in retail yards decreased in February and on March 1 were 24 per cent less than on Feb. 1. Stocks of anthracite were 40 per cent less than they were a month ago. The map shows how the supply of all coal—bituminous and anthracite—on March 1, 1923, compared with that on the corresponding date in 1922, when retailers had heavy reserves. All states east of the Mississippi except Minnesota had smaller stocks than a year ago.

substitute for anthracite. The February rate of delivery of bituminous coal in that territory was nearly 17 per cent higher than in January, which in turn was 20 per cent higher than the average rate of delivery in November and December, 1922.

Although large quantities of bituminous coal were secured by retail dealers to replace anthracite, demand in February was such that deliveries to consumers exceeded receipts, and total stocks of anthracite and bituminous combined fell off sharply. On March 1, 1923, the total reserve was 14 per cent less than that on Feb. 1, 1923, less than half that on March 1, 1922, and barely three-quarters that on March 1, 1920. The map in Fig. 4 shows how the stocks in each state on March 1, 1923, compared with those on March 1, 1922. It is seen that retailers east of the Mississippi had less coal on hand than a year ago. The only increase worthy of mention was that of 38 per cent in Minnesota, those in the Western States being small and of little importance.

Reports from the Northwestern Coal Dock Operators' Association indicate that the docks had been practically cleared of anthracite on March 1. It is estimated that the total quantity on hand on that date was approximately 10,000 net tons. On Feb. 1, 1922, there was 1,030,170 tons, on March 1, 1922, 821,448 tons, and on Feb. 1, 1923, 57,636 tons.

With Operators', Miners' and Public's Viewpoint Shown Coal Commission May Prescribe New Ethics

By Paul Wooton
Washington Correspondent of *Coal Age*

The outstanding feature of last week and one of the most significant events since the President's Coal Commission was formed, was the presentation of the argument and brief by Henry L. Stimson, counsel for the Bituminous Operators' Special Committee, on the policy and methods of the United Mine Workers of America. This presentation was in response to Governor Marshall's request for specific charges and evidence of violation of the rights of American citizens. There is abundant evidence that the commission realizes that the matters raised in this brief and which will be raised when the United Mine Workers make a similar presentation constitute the most dangerous rapids through which the commission must steer its craft.

The Senate Committee on Education and Labor, under the direction of former Senator Kenyon, of Iowa, undertook a similar investigation. The experience of that body was that it soon was flooded with a mass of testimony from each party to the controversy setting forth isolated cases and drawing from them a considerable variety of deductions. The history of the Kenyon investigation was that one outrage grew out of another and that it was impossible to trace back and ascertain who was responsible for the first overt act. Senator Kenyon soon gave up the effort to fix responsibility. He accepted the abundant evidence that a very unhealthy state of affairs existed and drew up a code of principles which recognized the rights of operators and mine workers and called upon each to put an end to the type of activities in which they were engaging.

It is fully expected that the Coal Commission will follow practically the same course. It is known that it will find indefensible acts for which each of the contesting interests is responsible. Since the police powers are vested in the state the opinion is held by some that the commission can do nothing more than set up a code and recommend that it be followed in the future.

Take Statements with Grain of Salt

There are no salt shakers on the commission's table, but it can be said, nevertheless, that some grains of salt are being added by members of the commission as they digest the statements made to them. It is believed that the commission is of the opinion that there is nothing startling in the effort of the United Mine Workers to unionize all mines. Every labor union seeks as many members as it can get. Unless a union gather into its membership a large proportion of the workers in a particular line of endeavor, collective bargaining would be impracticable. On the other hand, the commission is not surprised and regards as only natural, it is believed, that the non-union operators should resist determinedly all efforts to bring their men within the organization. It is thought that the commission recognizes that the real objection of the non-union operators to the union is not the various reasons usually cited but is the surrender of great market advantages that come with the ability to vary the wage scale in such a way as to take full advantage of the commercial situation.

Governor Marshall already has emphasized the fact that one illegal act does not justify another. It is safe to predict that, with the operators' point of view, the mine workers' point of view and the public's equity well understood and championed by members of the commission, a new code of ethics will be prescribed for the coal industry, with the probabilities favoring a scathing denunciation of various practices which have grown up in the employer-employee relationship at the coal mines. From the information that has become available as to the appearance of Mr. Stimson, some persons judge that the commission is in accord with the operators' contention that strikes constitute the real cause of the recurring shortages of bituminous coal. These shortages may have been prolonged and intensified by other contributing causes, but the operators seem to have established their contentions in that connection.

F. R. Wadleigh, Federal Fuel Distributor, appeared before the commission on April 6, at which time plans were perfected for co-ordination of the studies being made by the two agencies. It also was agreed that the commission would co-operate with the Bureau of Mines and the Federal Fuel Distributor in a study of anthracite standardization and preparation.

The statistical and technical compilations being made by the commission are progressing rapidly. During the first week of April ninety-six persons were added to the commission's staff, bringing the total personnel to 356.

It is probable that the retailers will make certain compilations of their own from duplicate returns on the questionnaires involved in that branch of the business.

C. A. Allen, Field Investigator, Dies

Carl A. Allen, in charge of field investigation of waste in the mining of coal for the U. S. Coal Commission, died of pneumonia Monday, April 9, in the Emergency Hospital, Washington, D. C. He had been ill ten days. The body will be taken to Denver for burial.

Mr. Allen was born in Colorado Springs and was educated at the Colorado School of Mines. Following his graduation he worked for four years as a mining superintendent and as a mining engineer in gold and copper properties, later engaging in consulting work, including problems of coal-mine engineering.

From 1911 to 1913 Mr. Allen was assistant professor of mining at the Colorado School of Mines, where he established a coal-mining course. In 1916 he joined the staff of the U. S. Bureau of Mines and spent a year and a half in charge of one of its mine-rescue cars, operating in the Montana and Wyoming district. In 1918 he was sent to Utah to direct the Bureau investigations in Utah, Wyoming and Idaho. An arrangement was made whereby he was engaged on a part-time basis to serve as the chief mine inspector for the State of Utah and as a member of the State Industrial Commission. His work with the Coal Commission was being done under a leave of absence from his regular duties. When he was taken ill Mr. Allen was engaged in field work in West Virginia for the Coal Commission.

Here's a Mule He Can't Ride

(From the United Mine Workers Journal)

"Not Guilty" Is Second Herrin Verdict; State Drops Remaining Cases

"Not guilty" was the verdict returned at Marion, Ill., in "bloody Williamson" County, April 6, closing the second murder trial growing out of the Herrin massacre of June 22, 1922. Thus a second time the State of Illinois was balked in its attempt to punish members of a mob which besieged a non-union strip mine, accepted the surrender of the 48 men within, and then shot and cut 21 of them to death with a brutality which made the massacre notorious the world over.

There remains a long list of names on the list indicted last autumn by a grand jury. The state, however, has thrown up its hands. All the charges of murder and conspiracy to murder have been *nolle prossed* on motion of Delos Duty, state's attorney, because the state feels that it is impossible to get a conviction before a Williamson County jury, no matter how direct the evidence against the defendants. Only the cases of larceny will be tried. Thus the whole effort of the state halts.

"I am not going to try any more," said Mr. Duty. "I have done my duty to the best of my ability. I have my personal opinion as to who committed those crimes and did all I could to convince two juries. It is a hopeless proposition." Attorney General Brundage, who gave a good deal of his own time to the prosecution, had little to say in Chicago, where he went at the end of the trial. He merely commented that the state couldn't get justice.

Under the law the case must be tried in the county where the crime was committed, so there is no further move to be made by the State of Illinois unless new evidence be found. The United States Department of Justice, which aided in working up the case against the long list of indicted men—most of them members of the United Mine Workers—has made no move to attempt federal prosecution. Acting Attorney General Seymour and Assistant Attorney General Crim, the latter in charge of criminal prosecutions, said in Washington April 7 that the decision of the Supreme Court in the Coronado case appeared to prohibit the government from intervening. In the Coronado decision coal mining was held to be in no sense interstate commerce. It is believed at Washington that there can be no federal action in the Herrin case unless it can be shown that there was a direct effect upon interstate commerce.

In Illinois the state's attorney, in a statement following the trial, said that two juries in the two Herrin cases had returned verdicts of acquittal "regardless of evidence" and that "intimidation, prejudice or downright dishonesty actuated them."

Assistant Attorney General Middlekauff said further: "Under rulings of the trial court, when jurymen were being examined, any man who admitted he had an opinion as to whether the massacre of the disarmed and helpless strip miners was lawful was disqualified for jury service. In my opinion, this is not the law in Illinois. Every man in Williamson County has repeatedly heard or read the details of this horrible and revolting tragedy. If he has no opinion whether such killings were lawful or unlawful he is, in my judgment, wholly unfit for jury service. At this time it seems that further trials would be farcical."

The six men who were defendants in this trial were Hugh Willis, a district official of the United Mine Workers; James Fontanetta, Oscar Howard, James Brown, Otis Clark and Bert Grace. They were charged with the murder of Antonio Mulkavich, one of the armed guards who defended the strip mine during the two-days' siege preceding the slaughter. The jury was out six hours and fifty-five minutes. The jury was made up of seven farmers, one student, one union painter, one merchant and two union miners.

Pennsylvania Coal & Coke Corporation Buys Two Cambria County Mines

Stockholders of the Pennsylvania Coal & Coke Corporation, at a meeting held in Philadelphia April 5, ratified the proposal of the Board of Directors to purchase from the Clearfield Bituminous Coal Corporation the West Branch Colliery, located near Barnsboro, Cambria County, Pa., and the Victor No. 12 mine of the Carrolltown Coal Co., located at St. Benedict, Cambria County, Pa. The purchase of the West Branch Colliery carries with it the equipment and railroad sidings, about 400 vein acres of coal lands owned in fee and about 30 vein acres held under leasehold. In purchasing the Victor No. 12 mine the new owners take over the sidings, about 400 vein acres of coal lands owned in fee and approximately 870 vein acres held under lease.

The report of the corporation for the year ended Dec. 31, 1922, shows net income of $496,929 after expenses, depreciation and federal taxes, etc. This is equivalent to $4.04 a share ($50 par) earned on the $6,169,500 stock outstanding at the close of the year, as compared with $668,330, or $5.43 a share, in 1921.

Productive Activity Higher in February

Further figures on February production in the United States, according to the Survey of Current Business, reprinted from *Commerce Reports*, show that the January high level was well maintained and even slightly bettered when account is taken of the difference in working days in the two months. On this basis additional new high records were made in wool consumption and copper production. Orders continue in large volume in most lines, and the unfilled orders on hand for many commodities, such as steel sheets, steel barrels and flooring, were the largest recorded in recent years.

Prices received by farmers for crops and live stock again increased, while the cost-of-living figure was unchanged from January. Retail distribution continued at high levels, while savings deposits increased throughout the country.

The index of mineral production for February was 106.5 compared with 1919 as 100, declining from 124.3 in January, owing to the decreased output of bituminous coal. The index of marketings of animal products declined from 113.4 in January to 95.3 in February, while the crop marketing index declined from 114.5 to 73.4. The index numbers for both minerals and animal products were higher than a year ago, but crop marketings were the lowest recorded for February in recent years, due to the small marketings of cotton and tobacco.

Fireproof Anthracite Reaches Wisconsin

Reports from the East about "fireproof anthracite" are not empty jests to Wisconsin. A car of culm shipped to Moede & Son of Manitowoc, Wis.—and for which payment in advance by wire was demanded and made—has been tested by John C. White, state power plant engineer. Ash content of 51.72 was enough to carry the case before F. R. Wadleigh, Federal Fuel Distributor. Mr. White's report contained this: "Moisture, 1.54; volatile matter, 5.10; fixed carbon, 41.64; ash, 51.72; sulphur, not determined. The dry ash was 52.51 and the heat value was 5,800 B.t.u."

Bituminous Operators' Special Committee Files Brief Blaming Union for Shortage and High Prices

In response to a request by the U. S. Coal Commission for specific charges and evidence of violation of the rights of American citizens in the coal industry, the Bituminous Operators' Special Committee, of which J. C. Brydon is chairman, filed with the commission April 5 a brief which brands the policy of the United Mine Workers as the chief deterrent to satisfactory supply and price of coal. The brief charges the union with destructive monopoly of labor and outlines a campaign of allegedly deliberate violence which the committee asserts that the union fosters to maintain and extend its rule.

Colonel Henry L. Stimson and Goldthwaite H. Dorr, of counsel for the Bituminous Operators' Committee, prepared the brief. A letter from counsel accompanies it, asking an opportunity to present proof of its allegations "at such times and places as the commission may set."

"The close of the war," the brief states, "found this nation with abundant coal reserves which had been accumulated under the war powers of the government. The periods of shortage and consequent abnormal price which have since occurred can be directly traced to the action of this organization and its allies in railroad labor. Even the deficiencies of railroad service such as are occurring today can be largely attributed to the effect which nation-wide strikes have had in preventing regular production and throwing upon the railroads unnecessary and abnormal peak loads.

"But for the expectancy and almost certainty of a tie-up of whole coal fields about every so often, most of the speculation would be taken from the coal business; mines unfit to compete under normal conditions would not open as they do whenever a strike or threatened strike puts an unnatural bulge into the price of coal; the railroads would not be called upon to haul two months' coal in one, or to dilute their service among twice as many mines as are needed for normal year-round operations."

Twelve Cases of Violence Cited

Colonel Stimson and Mr. Dorr outline twelve cases of violence on a large scale in bituminous fields since Jan. 1, 1919, including Willis Branch and Mingo in West Virginia and Herrin in Illinois. They maintain the cases show "such uniform characteristics as to necessarily postulate a common purpose and creed as well as a uniform system of tactics."

"Acts of intimidation and violence to extend and preserve this monopoly of the United Mine Workers are not sporadic, but systematic," the brief declares. "Whenever it is endeavoring to organize a district they flame up from the fundamental determination of this organization and its members in authority that no one shall be permitted to mine coal in an organized district, or one under attack by the organization, without its leave. Equally systematic is the resistance to the efforts of the state to bring to justice the agents of this supergovernment."

The brief points out that there is no excuse for a labor monopoly as a protection for workers in the bituminous industry. "Bituminous coal mining," it says, "is one of the most bitterly competitive industries in the United States. Bituminous coal is mined in thirty states of the Union and is hardly more susceptible of monopolization than the land itself underneath which it is found. Enormous reserves of such coal, still untapped, underlie vast areas of our country, awaiting future development."

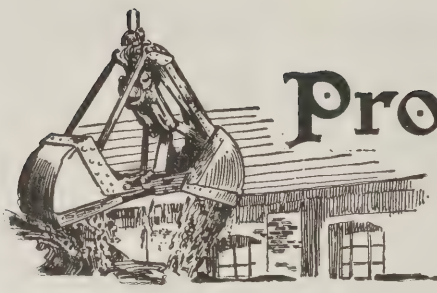
The Bituminous Committee, through its attorneys, seeks opportunity to prove before the Coal Commission that the principal cost of coal is labor; that wages in coal mining are double those in other industries because of the arbitrary power of the United Mine Workers of America; that "for collective bargaining this monopoly has substituted collective bludgeoning"; that the policy of the mine workers' organization "has laid the dead hand of monopoly on efficiency"; that the public pays the price for every unjust labor victory, and that further extension of the union would make government regulation hopeless.

In discussing the methods of the United Mine Workers the brief's first charge is:

"It supplants loyalty to the normal democratic machinery of government by loyalty to an irresponsible class-machine. (a) It creates a highly centralized organization in which a minority controls and overawes the majority by the weapons of incitement, abuse and intimidation. (b) It tends to crystallize and stratify the society of this republic into antagonistic classes. (c) It seeks to undermine the confidence of its members in the courts and other institutions of government."

In summing up their conclusions, Colonel Stimson and Mr. Dorr state: "We began our legal services in this matter in the hope that our work could be confined to the presentation of the results of economic investigation. The inquiry which we have thus far prosecuted has dispelled that hope. If an arrogant minority is challenging the American Republic by its attempt to fasten a monopoly of coal labor upon American industry and by its attempt to fasten an irresponsible class supergovernment upon American political institutions, purely economic questions sink into subordination.

"The effort to extort an artificial and economically unjustifiable wage scale by nation-wide strikes as the weapon is directed solely against the public. It is not organization against an employer; it is 'direct action' against the nation. It is the use of force for political ends.



"The resort of such a monopoly to the weapon of calculated violence in carrying out its ultimate purpose is not accidental; it is inevitable. The use of the unlawful method is a necessary sequence of the conception of the unlawful purpose. The combination of such purpose and such methods is as abhorrent to the democratic institutions of a republic as would be the use of military force to establish a military dictatorship.

"We do not mean for an instant to be understood as attacking the rank and file of the United Mine Workers of America. They are men of much the same instincts and character as Americans the country over. Normally the chronic acts of violence, a few of which we have recited, would be as abhorrent to them as to us or as to this Commission. The worst wrong worked by the leaders of this monopolistic conspiracy has been to substitute for normal American standards a false loyalty to organization and class which has so perverted the normal instincts of normal men that Straitsville, Cliftonville and Herrin follow as the natural and inevitable consequences. These consequences will continue to follow until this monopoly is curbed."

Operators' Charge Against Miners' Union Is "Fabrication of Lies," Says Murray

Officers of the United Mine Workers of America at International headquarters in Indianapolis have asserted that the bituminous operators' statement to the Coal Commission that the union carried on a campaign of violence to extend or preserve its hold on the mining industry is "untrue and unfounded." Union officials said they would seek an opportunity to disprove the operators' charges before the Coal Commission. Philip Murray, International vice president and acting head of the union while President John L. Lewis is absent in Europe, characterized the operators' statement as a "fabrication of lies," while William Green, International secretary-treasurer, merely said the allegations were untrue. The mine workers, he declared, do not have a monopoly on coal-mine labor in this country.

France handled the pick of the German army; it is much more difficult to handle the pick of the German miner. —*Woodstock* (Ont.) *Sentinel-Review.*

Production and the Market

Weekly Review

April is running true to form in the soft-coal market. Buying is very quiet and current output, which is holding up the late March figures, is being taken on current orders. With few exceptions large industrial buyers are not offering to contract, evidently waiting for prices to settle to the level at least of early 1922. The poorer grades of soft coal and steam sizes of anthracite are becoming increasingly difficult to move. Reports from Columbus are to the effect that some railroad contracts are being closed at from $2.25 to $2.50 for Ohio No. 8 mine-run. No-bills have been accumulating at small off-grade mines in central Pennsylvania for several weeks, and some of this coal has been and is being offered at $2, a figure below the cost of production. By comparison the better grades of steam coal are holding their own and some fair-sized blocks have been contracted above the current spot market.

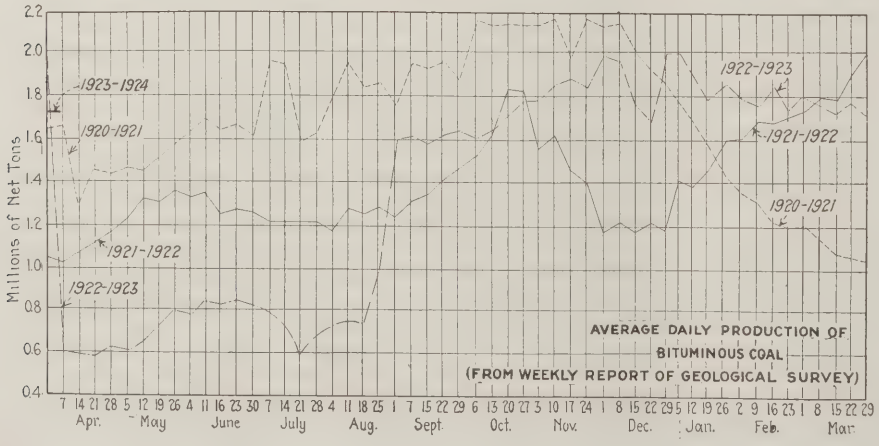
Coal Age Index of spot prices of soft coal declined 19 points from last week and stood at 233 on April 9, the corresponding average price being $2.82, as compared with $3.05 the previous week. Prices on Indiana, southern Illinois, Pocahontas and western Kentucky coals held firm, but nearly all other coals on the list registered declines.

Production continued on an almost even rate with that of the past few weeks, approximating 10,500,000 tons. Preliminary estimates by the Geological Survey indicate that the total output of soft coal for the coal year ended March 31, 1923, was 419,710,000 net tons, a decrease of 3.5 per cent as compared with 434,754,000 net tons in the coal year ended March 31, 1922.

February Consumption Heavier than January

The government report of stocks of coal on hand on March 1 confirms earlier estimates that consumption in February was heavier than in January and that stocks declined in February. The report shows 36,000,000 tons of soft coal on hand, a decrease of 2,000,000 tons as compared with 38,000,000 tons on Feb. 1.

Illinois operators report market recovery from losses on account of no market, but in southern Ohio, Pittsburgh and central Pennsylvania car supply was not improved.



The short-lived strike in the British mines did not serve to increase the demand for coal for export. Inquiries were few and accumulations at Hampton Roads increased. Some exporters are optimistic, however, and look for heavier demand during the next few weeks. Dumpings at Hampton Roads for the week ended April 5 were 400,267 net tons, as compared with 370,823 net tons during the previous week.

Demand Good in Midwest

Considerable coal moved in the Midwest because of continued cool weather, demand around Chicago being heavy enough to absorb nearly all the coal produced, and there was some talk of car shortage not only in nearby fields but in the Eastern smokeless regions.

"The anticipated decrease in production on account of the pre-Easter holidays in the week ended March 31," says the Geological Survey, "did not occur and for the third successive week production was in the neighborhood of 10,400,000 tons. The present estimate of the total soft-coal output in the last week of March is 10,414,000 net tons, including coal shipped, mine fuel, local sales and coal coked, which is a decrease of only 10,000 tons from the revised estimate of the week preceding.

"Preliminary reports of cars loaded in the week April 2-7 showed 17,953 cars on Monday. Thus production on that day, which was a double holiday—Eight-Hour Day and Easter Monday—was equal to 45 per cent of the average for recent Mondays. Loadings on Tuesday were approximately 33,000 cars and did not show the usual recovery following holidays. The loadings during the

first four days of the week were 14 per cent less than in the week before, and the total output for the week will be around 9,500,000 tons."

Domestic sizes of anthracite moved rapidly. Demand is strong and the companies as well as the larger independent producers are in some instances booked heavily ahead. Independent egg, stove and chestnut coals are commanding premiums as high as $1.50 above company schedule. The steam sizes move slowly.

Midwest Moves Much Coal

Operations throughout Illinois and Indiana continued to ship domestic sizes in considerable volume during the past week, due to persistent cool weather. On the whole there was no trouble filling orders. Steam buyers sat back and took what screenings were produced. The expected increase in the price of steam sizes did not occur. Southern Illinois screenings still hang close to $2 though lower grades sell under the market, as always. This means that some screenings from Franklin County went as low as $1.75.

Car supply was ample for a full three days' running time through the southern Illinois fields. Many mines used all they got. But a number of big producers have been shut down, so that the capacity of the field is considerably reduced. In the Duquoin and Jackson County fields there was some activity but railroad tonnage was comparatively light all week and no mine worked over three days. The Security mine in this region, which has been down for about three weeks because of flooding, is about ready to operate again.

The Mt. Olive district remains in an unhappy state because the operators there are so badly undersold by southern Illinois independents and by entire neighboring districts. Mt. Olive producers are trying to get $3.25 for 3-in. lump while Franklin County 6-in. lump can be had for as low as $3. Central Illinois 6-in. lump goes for $2.65@$2.75.

St. Louis Business Is Fair

Seasonable weather keeps domestic coal moving in small quantities in St. Louis and in good demand for the cheaper grades. The dealers are fortunate this year in being able to clean up all of their old stocks. The April retail prices which went into effect of $5.50 on Standard, $6.25@$6.50 on Mt. Olive and $7.50@$7.75 on Carterville have kept the dealers fairly active. Anthracite came down from $16.25 for all sizes to $15.75 for the large sizes and $16 for the

* Net tons, f.o.b. mines. † Advances over previous week shown in **heavy type**, declines in *italics*.

Coal Age Index 233, Week of April 9, 1923. Average spot price for same period $2.82. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the war Industries Board.

small sizes, while byproduct coke is $11 and gas-house $10.50, with smokeless egg and lump at $12.50.

Strike Concentrates Kentucky Business

The strike in the southern section of western Kentucky, which affects about one-third of the field is resulting in better demand and car supply for the balance of the field. It is reported that the operating sections of the field got 100 per cent car supply during the week. The strike has not forced prices higher. Demand hasn't been sufficient for that. Mines have not been able to run much better than two to three days a week in spite of the plenitude of cars.

Prices as a whole are quite steady. There is a firmer market on screenings, and this market is likely to show advance. Lack of prepared-coal orders is resulting in much slower running on screened coal, with the result that screenings are getting scarcer and prices firmer. While some screenings have been sold as low as $1.50 a ton in past weeks, with the general market at from $1.60 to $1.75 or $1.85, it is reported that most of the screenings last week were quoted at around $1.85@$1.90 on actual sales.

Louisville feels that the general outlook for coal business during the summer is fair in spite of the fact that high ocean rates and combinations among Easterners to boost prices have driven a good deal of foreign trade away and stopped the flow of coal that had started toward the Atlantic piers. Lake trade is expected to be slow in opening but industrial demand generally is counted on to assume large proportions. Country-wide stocking on a bigger scale than usual is expected.

Northwest Expects Lake Trade to Lag

Up around the Head-of-the-Lakes it is generally agreed now that the Lake season will not open on April 20, as prophesied. The date is now set forward to about May 1 because a good deal of heavy ice still locks the harbors and passages and the weather is still distinctly cold.

There is no anthracite at Duluth and Superior. Householders with magazine stoves which will burn only hard coal and whose coal bins are empty are so thoroughly up against it that the Mayor of Superior asked those in the city who had coal to divide it.

In spite of this scramble for hard coal and in spite of the fact that there remain but 400,000 tons of free bituminous on the docks to last until coal arrives by vessel, there is little market for the bituminous.

Milwaukee is little worried just now. Enough hard coal is in hand for the demand and bituminous is arriving steadily. The only real difficulty is a congestion of terminals which is expected to be cleared soon. Given a spell of fair weather, the car ferries are counted on to move a good deal of coal across the lake from Ludington, Mich. Some consignments from Toledo are still undelivered though they have been three weeks on the way. Rail anthracite has been arriving through Chicago.

Western Trade Softens

April 1 in the Kansas City region brought the usual scramble to unload domestic sizes on hand at once. In such a time quotations show wide spreads, coal bringing what it will. Kansas lump and nut sell all the way from $4.50 down to $3.25.

Domestic coal in Colorado is moving fairly well, with mines running an average of 64 per cent of the time, but steam sizes drag. The state produced 1,909,000 tons of coal during January and February and is now running better than 100,000 tons a week.

In Utah most mines are getting only two days a week. Soft weather and an anticipated drop in price have held the market flat. Carbon County lump sells for $4.50@$5; egg, $3.50@$4, and slack, $1.25. Contracting is dull. Metals are on the upgrade however, improving the market for coke. The Utah Fuel Co. made 21,000 tons in March selling for $8.50 at the ovens. Car supply is ample and there are no labor disturbances in the state.

Lull in the Cincinnati Market

Buyers and sellers in the Cincinnati market are marking time. Lake buyers are out bargain hunting and although the Coal & Ore Exchange permits will not be issued until April 15 at the earliest, they have been picking up what spot tonnage they can around $3.25@$3.50, figuring to pay demurrage and still get coal at a lower price than the $4 which most shippers are holding out for. The shut down of the Kanawha mines that refused to accept the wage scale of the Miners' union had but little effect on this market.

Softness is developing in the Columbus market and it is believed it will continue until the lake season is well under way.

The Cleveland market was quiet. Not much contracting is being done because operators are not disposed to sell ahead at current quotations.

The Pittsburgh market turned still softer during the week. There was some buying of lake coal, but only in odd lots.

No improvement was noted in the Buffalo market. Buying was slow, and it looked as if consumers were determined to hold off for some time to come.

Dullness Pervades New England Market

There are few bright spots in the current market in New England. There are only scattering purchases and those mostly on the part of small users. Many of the larger buyers are postponing action until prices are more nearly on last year's level. There seems no anxiety whatever over the future and the agencies find it difficult to place tonnage

more than a few weeks in advance. Practically all quotations are at a lower point than a fortnight ago, and with many operators it is a question whether they would not be better off to close mines for the present, especially in high-cost sections in central Pennsylvania. The prospect is for continuing dullness through April and May, and only by constant effort will shippers be able to place any considerable output.

Accumulations at Hampton Roads have mounted steadily since March 15. Upward of 300,000 tons was on cars early the past week at Norfolk and Newport News, the larger proportion of it being navy standard coal. New England industries are only mildly interested in contract quotas, and there is a general slackness that used to be considered characteristic of July and August.

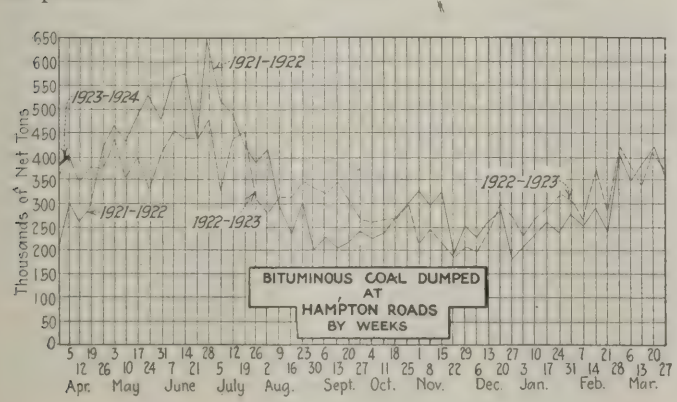
Quotations on cars at Boston, Providence and Portland are at least 50c. off from a week ago. Pocahontas and New River that were then selling at $9.25 per gross ton are now an easy buy at $8.75, a price that coincides with the April contract basis named by one of the large producers. While there still are delays in handling cargoes at this end the congestion is less evere, but there is still enough detention to make coal factors chary of sending cargoes forward unsold at their own risk.

Throughout the central Pennsylvania districts there is urgent need of orders. This territory is being thoroughly canvassed, but softening prices on the smokeless coals from Hampton Roads make the area open to the all-rail route more and more circumscribed. Ordinary Clearfields of moderate preparation have sold recently at prices well down to the $2.25 mark, although certain specialties of most approved grade have commanded $3.50@$3.75, and even $4.

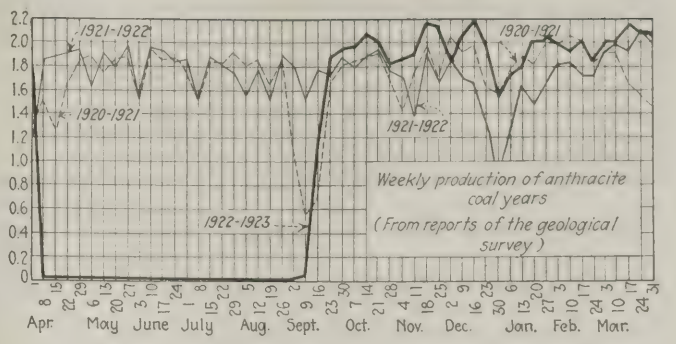
New York Looks for Brisk Summer

Buyers in the New York market continue to mark time. There was practically no demand but there was a better feeling due to increased inquiries. A brisk summer is looked for beginning with the opening of the lake season. Buyers are taking coal in small quantities.

The Philadelphia market was slow. A survey shows that outside of the big utilities, stocks above ground are moderate and consumers show little inclination to add to them. The local tide business while a trifle better has not at any time recently been sufficient to stimulate domestic demand.



Export Market Growing at Baltimore



The continued growth of the export market is one of the outstanding features at Baltimore. Some congestion is already noted at terminals where supply is running in excess of demand. Revised figures show that for the first three months of this year 109,688 tons of cargo coal was shipped from Baltimore in 23 vessels. The total dumpings at Baltimore for the year 1922 were 107,735 tons.

Anthracite Output Holds Up Despite Holidays

Producers are having no trouble to move their domestic coals. The steam coals are accumulating however, and independent operators and shippers are disposed to sell below company quotations.

Retail dealers are ready to take all the larger coals they can obtain and are making deliveries to consumers as rapidly as possible.

"Contrary to expectations, production of anthracite in the week ended March 31," says the Geological Survey, "was not seriously curtailed by observance of Easter holidays. Daily reports of cars loaded, furnished by the American Railway Association, indicate that production on Good Friday amounted to 65 per cent of the output on other recent Fridays and production on Saturday compared favorably with preceding Saturdays. The total production for the week is estimated, on the basis of 38,397 cars loaded, at 2,008,000 net tons, including mine fuel, local sales and dredge and washery output.

"Early returns for the week April 2-7 indicate a general observance of Eight-Hour Day, April 2, as a holiday, and little if any anthracite was produced. Production was approximately 70 per cent of normal on Tuesday and further, but not full, recovery was made by Wednesday. In view of the uncertainty as to the rate of production maintained in the second half of the week it is impossible to fore-

Coke Production Increases Slightly

Production of coke during the week ended March 31, estimated by the Geological Survey from reports of cars loaded by the principal coke carriers and in part from reports of producers was 388,000 net tons, as compared with 384,000 tons during the previous week.

Foreign Market And Export News

Export Orders Swamp British Mine Owners; Rhonnda Miners Settle Trouble

British mines continued their heavy production during the week ended March 24, when 5,703,000 tons of coal were mined. This was but 18,000 tons below the previous week's record, which was the highest for any week of the present year, and but 39,000 tons less than the record for 1922, 5,742,000 tons having been the output for the week of Dec. 26.

It was reported that the strike of the miners in the Rhonnda coal fields had been settled and that the men would return to the mines on April 10.

Fully 100 vessels were said to be in the Welsh ports awaiting their turn to be loaded.

Chief pressure on the Welsh market comes from France, Italy and Germany. From these sources buyers appear anxious to cover themselves right up to the winter, and well over 250,000 tons has been sold to Germany.

In addition to the inquiries from France, Italy, Germany, and elsewhere, Russia is reported in the market for heavy quantities to be delivered over the coming Baltic season.

All mines are sold up to the end of March, and have little to offer for April, while buyers are anxious to purchase for at least six months ahead.

The French demand is easier, in some cases to the extent of withdrawing inquiries already in hand. Germany will need coal supplies for some time to come, but is at the moment awaiting developments. Belgium is less eager in her inquiries. American coal is offering freely, so that buyers feel fairly safe in holding off.

Orders Flood French Collieries

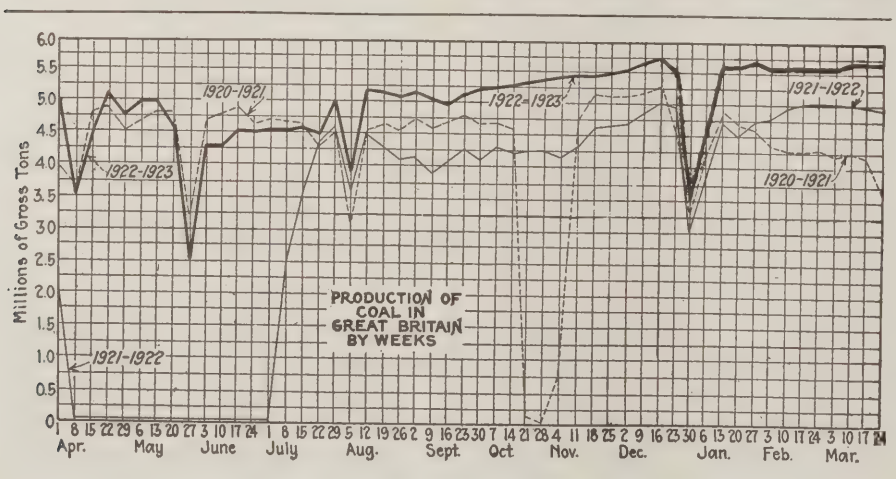
Collieries of the Nord and Pas-de-Calais are flooded with orders far exceeding their production, many from consumers who are trying to avoid paying the high prices quoted for British coals. Importation of Dutch coals is increasing, while Belgian coal imports show a tendency to decrease. In February, France imported 43,000 tons of raw coal from Holland.

A meeting was recently held in Paris between representatives of French and Belgian collieries with a view of coming to an agreement on prices to be charged for domestic coals supplied to the Paris market during the coming summer, but no agreement was reached at that time owing to French collieries quoting prices considered by the Belgians as too low.

Hampton Roads Export Demand Good

Business at Hampton Roads slackened slightly last week although the general trend was upward and coal movement continued on a par with March business, when records for twelve months were broken. Export business held up well, with further prospects of this business to stimulate the market.

Prices fell slightly, and whatever dullness was apparent was attributed to this. Coastwise business was down, somewhat, though bunkers held good. Prospect of shipments to England, in case labor difficulties there should prove serious, gave stimulus to the market.



Unusually large supplies of coal were on hand at the piers, and the car situation showed further improvement. Domestic business fell in the wake of spring, and many retail dealers were preparing to devote their energies to the other side of their business, that of distributing ice.

Holland's Coal Production

Although the production of bituminous coal in the Province of Limburg, Holland, 1922 was nearly 600,000 tons greater than in 1921, Holland is still largely dependent upon foreign coals. In 1922 there were produced in the Province of Limburg 4,500,000 tons of bituminous coal, as compared with 3,920,000 tons in 1921 and 3,940,000 tons in 1920.

There were imported into Holland in 1922 6,220,000 tons of coal and 234,000 tons of coke, as compared with 4,890,000 tons of coal and 200,400 tons of coke in 1921. Of the coal imported in 1922 4,530,000 tons came from Great Britain and 1,190,000 tons from Germany. In the previous year 1,770,000 tons came from Great Britain and 1,280,000 tons from Germany.

In 1922 there were exported 2,260,000 tons of coal and 350,000 tons of coke, as compared with 1,930,000 tons of coal and 120,400 tons of coke in the previous year. Of the exports in 1922 Germany received 354,000 tons, Belgium 549,000 tons and France 249,600 tons.

News Items From Field and Trade

ILLINOIS

The recent **refusal of the Interstate Commerce Commission to grant permission for the construction of the Jefferson & Southwestern R.R.**, has somewhat upset the plans for the new mine at the new townsite of Nason by the Illinois Coal Corporation. The road was to be used for the heavy haulage of material, etc., during the developing and construction of the mine. An appeal has been taken on the decision and if the outcome is still unsuccessful, the next step may be to build an extension spur from the nearest point of the Chicago & Eastern Illinois R.R. near Ina, or from the Chicago, Burlington & Quincy R.R. at Waltonville, to the mine site.

A. H. Vogt assumed office on April 2 as treasurer of the Illinois Coal Corporation, to which he was elected recently. For six years Mr. Vogt was comptroller of accounts of the Federal Reserve Bank of Chicago, in which capacity he devised a system of accounting for the United States Government fiscal agency operations of the bank which was adopted by several other Federal Reserve banks. Mr. Vogt also has been a member of the Federal Reserve committee on economy and efficiency for some time.

Proposals for furnishing fuel for the use of army stations in miscellaneous amounts between April 20, 1923, and March 31, 1924, will be opened April 12 by the Quartermaster Supply Officer, Chicago General Intermediate Depot.

The M. & B. Coal Co., Danville, has been incorporated with a capital of $25,000, incorporators, L. T. Mauck, Wm. Mauck, Louis Bock, Louis F. Bock, Paul F. Bock. Correspondent, Louis Clement, 1102 First National Bank Building, Danville.

C. W. Smith, of Chicago, chief engineer of the **Illinois Coal Corporation,** has arrived at Mt. Vernon, Jefferson County, to take active charge of the sinking of the company's new mine near there. The company also plans to **establish the town of Nason,** near the mine site, the town being named after A. J. Nason, head of the coal company. Engineer Smith has stated that all preliminary work and details are complete and that **actual sinking will be started soon.** It also is estimated that six months will be required to sink the two shafts to the coal.

The Free Belle Mining Co., Freeburg; capital, $50,000; has been incorporated by H. F. Driemeyer, O. E. Altrogge and S. J. Fowler. The company will mine and deal in coal, coal products and minerals. Correspondents, Pope & Driemeyer, 24 N. Main Street, East St. Louis.

The Valley View Mine, at Coal Valley, **has been closed for a few months.** The mine is owned by Sachville & Wynn. The shaft will be closed the greater portion of the spring and summer months and during that time, improvements of various nature will be made in and around the plant.

Mine No. 2, better known as the **Hart-Williams mine,** at Benton and owned by the **Chicago, Wilmington & Franklin Coal Co., has suspended** operations for six weeks or longer. This is the first colliery of that company to be closed this spring, and the fourth large mine in Franklin County to shut down. The Hart-Williams mine employed over 500 men.

J. C. Micheals, president of the Chest Creek Coal Co., of Chicago, has been found guilty in federal District Court of trying to defraud several railroads by claiming losses in shipment which did not occur. He has not yet been sentenced but the maximum penalty for the offence is 20 years in prison or $50,000 fine or both. The Chest Creek Coal Co. has been heavily involved in Chicago graft scandals, charged with shortweighing the school department.

A. K. Mordue has left the C. M. Moderwell organization in Chicago and joins the **Southern Coal, Coke & Mining Co.,** whose Chicago office has been moved into the Peoples' Gas Building. **W. K. Kavanaugh,** president of this company, has returned to St Louis from a long trip through the West Indies and Central America.

The Glenn Coal Co., Astoria, has been chartered with a capital of $12,000 to mine and deal in coal. Incorporators: E. G. Bader, M. W. Hughes, David E. Thomas.

The Utilities Coal Co., 332 South Michigan Avenue, Chicago, has been incorporated with a capital stock of $200,000. Incorporators are Cyrus H. Adams, Jr., Ben H. Matthews, Edward M. Bullard. The company will mine and deal in fuel.

INDIANA

The Clinton Coal Co., of Clinton, has contracted with the Roberts & Schaefer Co. for the complete installation of a new steel tipple at Clinton. This tipple is to replace the present wood structure and will be equipped with combination installation of Marcus screens and bar screens and "RandS" loading booms.

The Bertelsen Coal Co., Evansville, has been organized with a capital of $10,000, to deal in coal mines; directors, Jeppe Bertelsen, Katharine Bertelsen and Lowry Bertelsen.

J. R. Wasson, Oakland City, has purchased for $10,000 at a receiver's sale the property of the defunct Muren Mining Co. The property consists of three mines along the Southern Ry., with a daily output of 550 tons. Two of the mines are small slope mines with an output of eighty tons each, but the largest mine is equipped with a tipple and has a production of 400 tons daily.

The General Fuel Corporation, Terre Haute, has increased its capital from $2,000,000 to $2,400,000; $200,000 of the increase is in preferred stock.

The Howe-Coulter Coal Co., anticipating a heavy fall business in coal, has started driving entries in its No. 1 mine at Petersburg. A double shift of 60 men each is employed at the mine, and the work is being divided among the 450 employees of the company. **Many big mines in Pike County, except the strippers,** are operating only one or two days a week. Owing to the cut of $1 a ton on coal, some operators in Pike County say they cannot operate their mines at a profit, but will improve their properties. The stripping mines can handle coal at much less expense than the deep mines, and are operating full time.

The Fort Wayne Board of Works has authorized the city light department **to advertise for bids on 40,000 tons of coal—** the most the city ever contracted for. The city wants shipments to be made every week from May 1, 1923, to April 30, 1924.

At the seventeenth annual meeting and dinner of the Indianapolis branch of the National Metal Trades Association, held April 6, at the Claypool Hotel, Indianapolis, **E. L. Greever,** general counsel for the non-union coal operators' associations of West Virginia, **delivered an address on the open-shop struggle in the coal fields.**

KENTUCKY

The Liberty Coal & Coke Co., Louisville, recently chartered with a capital of $50,000, to operate mines in the Pineville territory, has opened sales offices in the Inyer Southern Building, Louisville. M. S. Barker, A. R. Anderson and R. R. Atkins, of Pineville, are incorporators. The company has production at Bell County mines.

The Young & Morgan Coal Co., Providence, Webster County, capital $12,000, has been incorporated by E. M. Young, J. E. Morgan and Anna B. Young, all of Providence, western Kentucky.

The Howard Elkhorn Coal Co., of Johnson County, capital $36,000, has been incorporated by Paintsville men, including E. G. Howard, of Sublett; L. C. Davidson, of Huntington, W. Va., and H. B. Stanbaugh, of Paintsville.

The Frozen Creek Coal Co., Jackson; capital, $12,000 has been incorporated by S. B. Williams, Elihu Reynolds and M. F. Reynolds.

The Denver Coal Co., Johnson County, capital $50,000, has been chartered by Paris Pelphrey, Alsia Pelphrey and W. L. Pelphrey, all of Denver, Ky.

Thomas C. Fuller, of Lexington, **filed suit for an injunction and accounting** at Frankfort, April 3, in the federal court, claiming **a one-tenth interest in the 120,000 acres of mountain land** sold recently by the F. S. Peabody syndicate, of Chicago, **to the Fordson Coal Co.,** a Henry Ford corporation. The defendants include Harry Payne Whitney, New York; Stuyvesant Peabody, Chicago, trustee of the F. S. Peabody syndicate; Samuel Insull, Chicago; William Wrigley, Jr.; Williams & Peters, Syracuse, N. Y.; the Peabody-Houghteling Co., Chicago; Marks Manufacturing Co., George F. Getz and the Semet-Solvay Co., Chicago; John P. Hopkins, Evanston, Ill., and the Fordson Coal Co.

The I. X. L. Coal & Mining Co., Bell, capital $25,000, has been incorporated by M. D. Bell, F. R. Martin and J. E. Bill, all of Pineville.

The American By-Products Coal Corporation, Bell; capital, $150,000, has been incorporated by M. J. Moss, Pineville; S. M. Loomis and Adolph Levy, Cincinnati.

The White Elkhorn Mining Co., Letcher; capital $25,000; has been incorporated by Thomas Fugate and J. W. Craft, Hazard, and H. A. Price, Detroit, Mich.

The **Tug River Coal Corporation,** capital $5,000, has been incorporated by Hubbard R. Petty, W. E. Caldwell, James Willey and R. H. Lucas.

Coal operators of Perry County, after a long conference with the State Tax Commission **failed to convince the Commission that the assessment of coal lands and mining equipment in Perry County was placed too high.** Members of the commission stated at the close of the conference that the matter had been taken under advisement but indicated that they were not wavering from their stand for the original assessment. Perry County lands, rich in minerals, were assessed at approximately $19,000,000 this year. This represented an increase of approximately $5,600,000 over the previous assessment. Representatives from Pike County appeared before the commission in the interest of a reduction on the assessment for their county but no agreement was reached. Pike County's assessment of approximately $19,000,000 was raised to $28,000,000.

Development of large areas of virgin coal lands in Butler County is visualized as the result of **the construction of a railroad from Greenville to Rochester,** under a charter granted the Greenville Eastern R.R. Contracts for the construction of 14 miles of the road already have been let. This will be the first railroad in Butler County. The incorporators of the road are J. W. Thompson, of St. Louis; H. E. Barber, of Marion, Ill.; W. J. Lester, of Cleveland; J. L. Rogers and Hubert Meredith, of Greenville.

George R. Dempster of Knoxville, Tenn., president of the Dempster Construction Co., which has obtained the contract to strip and mine coal deposits in Hopkins County, reports that this is **one of the biggest projects in the South** and he estimates that it will take several years to complete the job. The company will work on more than 2,000 acres and will develop the project with steam shovels. Dempster estimates that the company in its operations will remove 100,000,000 cu. yd. of earth and stone and that the tract will yield an estimated output of 16,000,000 tons of coal.

John Hoffman, Judge S. S. Helburn and State Auditor John Craig, all connected with the Hignite Coal Mining Co., were in Louisville recently and called upon President Mapother of the Louisville & Nashville, who **promised them rail connection** with that carrier.

The Rogers Bros. Coal Co., of Ashland, is making preparations to develop its holdings on Turkey Creek, Pike County. The plans of the company will entail the expenditure of more than a million dollars.

K. U. Meguire, of the Harlan Coal Co. interests, Louisville, has arranged to enter the western Kentucky field with **a big stripping operation four miles north of Dawson Springs,** on a new branch of the Illinois Central R.R. from Central City to Madisonville, Ky. Work on this branch line has just started, and development of the mine hardly will start until the railroad reaches the property, and makes it possible to get in steam shovels and equipment by rail. A tipple will be erected with a capacity of 50 to 75 cars per day.

MAINE

The State Fuel Administration was abolished as of April 1, F. R. Wadleigh announces.

MARYLAND

The Black & Decker Mfg. Co., Towson, manufacturer of portable electric tools, announces that **the regular quarterly dividend has been declared on preferred stock,** and that the payment of **dividends on common stock has been resumed,** after having been discontinued for about a year following the recent depression.

MASSACHUSETTS

The State Fuel Administration was abolished on April 1, F. R. Wadleigh states.

The House Committee on Rules voted March 29 **to report with amendments an order** passed by the Senate **for the appointment of a special joint committee to investigate the coal situation.** Changes made centered largely on the question of expense. Under the amended order a committee consisting of three members of the Senate and six members of the House would "investigate the emergency relative to the production, transportation and distribution of coal, with a view to the adoption of such measures as may aid in preventing a recurrence and in securing a continuous and adequate supply of anthracite coal of good quality at reasonable cost and an equitable distribution thereof."

MICHIGAN

To further insure ample coal supply for manufacturing requirements, and to obviate coal shortage delays, etc., **the Ford Motor Co. has purchased 1,000 coal cars** of 55-ton capacity each, to transport coal over the Ford Railways.

MINNESOTA

Federal fuel commissioners are working upon a survey of fuel conditions in the Twin Cities, in order that coal shortages may be averted and prices kept stable in the future. From statements made, it appears that they are likely to recommend warehouses in which to store coal against a shortage. Their investigation will follow the course of coal from the mine to the lower Lake port, thence to the dock, and by rail to the point of consumption. If they are correctly quoted, the warehouses would be established by private capital. It is pointed out in the coal trade that if the plan were economically feasible, private capital, which has already invested millions in docks for the trade of this region, would hardly have refrained from spending a little more, to guard its business.

MISSOURI

The Hannibal Coal Co., of Hannibal, pulled off a new stunt recently when it **shipped more than a ton and a half of coal by parcel post.** The coal was put in white muslin sacks and wrapped in paper, 25 lb. to the sack. The shipment consisted of 147 sacks. The coal shipped was sample fuel and was sent to blacksmiths in Illinois and Missouri. The cost of shipping the coal was $36.03.

The Star Coal Co., of Bevier, **has just signed a contract with the Burlington R.R.** Delivery will start at once. The company recently installed a screen.

MONTANA

A new commercial coal mine is being opened up in the Bird Tail area on the old ranch of J. J. Farrell, Sr., near Fort Shaw. The coal veins, which are of Eagle formation, yield semi-bituminous coal.

NEBRASKA

The Nebraska State Legislature has tendered an **official invitation to Henry Ford to scan that state's water-power possibilities** and to develop the 360,000 horsepower which the government says Nebraska rivers will produce. Harnessing the water-power resources of the state would save 4,000,000 tons of coal annually, and the development of white coal to supplant the chocolate lumps which the state must now import would attract a large population.

NEW YORK

F. R. Wadleigh, Federal Fuel Distributor, is to be the speaker at the luncheon to be held at the Waldorf-Astoria, New York City, on April 12 by the Smokeless Coal Operators' Association.

Coal purchased by the U. S. Shipping Board in New York for its steamship lines **will be inspected and sampled by the U. S. Bureau of Mines.** The work will include sampling of foreign coal remaining in bunker upon the arrival of these ships in New York as well as sampling the coal while it is being loaded on these vessels in the New York port.

Assembly Print No. 2,025, by Assemblyman O'Connor, adds a new section, 2147-a, to the penal law, **prohibiting the sale of ice, coal and wood on Sundays.**

Senate Print No. 1,724, by Senator Fearon, amends Section 225 of the Farms and Markets Law so as **to fix the size of sacks and bags used in the sale of coke, charcoal or kindling wood.**

Burns Brothers announced April 3 that the meeting of stockholders set for April 9, to act upon a proposed readjustment of the capital stock of the company, has been postponed to a date to be fixed later.

C. Tracy Ryan, formerly deputy commissioner of the Tidewater Coal Exchange at New York and recently associated with Dexter & Carpenter at their New York and Boston offices, **is now affiliated with the New York office of the Iron Trade Products Co.**

J. G. Bradley, president Elk River Coal & Lumber Co., Dundon, W. Va.; **George H. Cushing** and **J. D. A. Morrow,** of the Morrow-Callahan Coal Co., Cincinnati, Ohio, **are to make addresses at the annual meeting of the United States Chamber of Commerce,** in New York City, May 8-10. The talks will be before the Chamber's Natural Resources Production group, which will hold a session devoted to discussion of coal problems at the Waldorf-Astoria on the afternoon of May 9. Mr. Bradley's topic will be **"Labor and Its Relation to the Cost of Industrial Coal"**; Mr. Cushing will speak on **"Economic vs. Legislative Method of Settling the Coal Problem,"** and Mr. Morrow's talk will be on **"Some Problems of Coal Distribution."**

NORTH DAKOTA

Vigorous propaganda is being instituted on behalf of the lignite industry of North Dakota, with frequent publicity in which that fuel is credited with possibilities for an industrial development of the Northwest the like of which Pittsburgh never dreamed. Visions are portrayed of the removal of the steel center to the Twin Cities; of developing immense power plants at the scene of the mines, and transmitting power electrically to the Twin Cities, and of briquetting lignite to undercut the price of hard coal with consequent capture of a big domestic market for this fuel.

OHIO

When the Board of Purchase of Columbus opened bids April 4 for 13,000 tons of coal for various city departments for the coming 90 days it was found that Hatton, Brown & Co., Inc., was low on the municipal light plant for 7,200 tons of Hocking nut, pea and slack at $1.60 at the mines. William Harman, a wholesaler, was low on 3,300 tons for the water works department and 200 tons for the garbage reduction plant at $1.43. **It is doubtful if the contracts will be awarded,** as some of the Board of Purchase favor the policy of buying on the open market.

The Steam & Heat Coal Co., Bridgeport, has been chartered with a capital of $100,000 to mine and sell coal in the Pittsburgh No. 8 district. Incorporators are W. E. Thomas, J. C. Heinlein, Jacob Meister, George Meister and Fred Meister.

The Stannard Coal Co., Cleveland, has been incorporated with an authorized capital of $10,000 to mine and sell coal both at wholesale and retail. Incorporators are Max P. Goodman, Mollie Friedman, Meyer Gordon, Charles Auerback and Benjamin F. Sacharow.

The Cincinnati Coal Exchange has voted to invite the Michigan, Ohio and Indiana Retail Coal Dealers' Association to meet in Cincinnati this year. It may be that the meeting will be held at the same time as that of the American Wholesale Coal Association in June.

Papers have been filed chartering the **No. 6 Hocking Coal Mining Co.,** Cannelville, with a capital of 500 shares of no par value, designated by Harold H. Burton and others.

The W. T. & K. Coal Mining Co., Akron, has been incorporated with a capital of $10,000 to mine and sell coal by Murray S. Parker, Orella M. Parker, Teresa Wenst, Alice B. Kraus and J. L. Edwards.

The East Cadiz Coal Co., of Cadiz, has been chartered with a capital of $100,000 to mine coal and deal in coal and coke by John M. Wheeler, Agnes W. Vance, Harry W. Vance, S. B. Hedges and J. W. Reed.

The Margretta Collieries Co., of New Philadelphia, has been incorporated with a capital of $115,000 to operate coal mines, and to buy, sell and deal in coal at retail. Incorporators are H. C. Schneider, Roscoe Oberlin, John C. Thomas, J. W. Edwards and John T. Maurer.

The J. C. Rosso Coal Mining Co., chartered with an authorized capital of $100,000, has been organized by the election as president and manager of J. C. Rosso, a well-known coal mining man from Pittsburgh. An option has been taken on a large tract in the eastern Ohio field, which will be developed. Incorporators are J. C. Rosso, R. H. O'Brien, E. G. Bowerman, H. G. Kates and R. E. Bothwell.

Shipments by river on an unusually large scale are planned by the Cleveland & Western Coal Co. in connection with the opening of a new mine at Powhatan, Ohio, which will rank as one of the largest in the country. With a view to having the most modern facilities for such river shipment, the company has awarded to the General Contracting Corporation of Pittsburgh, Pa., a contract for the construction of a huge tipple, extending out over the river. The company also is arranging for a harbor with capacity for the largest boats and barges.

PENNSYLVANIA

For the part she played in bringing relief to Reilly No. 1 mine at Spangler, Cambria County, on Nov. 8, 1922, when 78 lives were lost and about 35 men were rescued alive through prompt arrival of relief forces, **Miss Mary Agnes McCarthy,** operator for the Bell Telephone Co. at Barnesboro, **has been awarded one of the eight Theodore N. Vail bronze medals** issued in the Pennsylvania-New Jersey division of the Bell company "for conspicuous acts of public service in the telephone industry during 1922." Miss McCarthy's brother-in-law, Martin McAvoy, was killed in the disaster. She went on duty at 8 o'clock in the morning, not knowing of the explosion. She remained on duty throughout the day, directing the messages to and from the mines and called physicians and sent emergency calls to all sections.

A decision by J. W. Brown, a deputy Attorney General, to Joseph J. Walsh, chief of the Department of Mines, holds that it is the duty of a mine operator to keep a headman and footman at their proper places during the entire time any persons are underground and is not permitted to withdraw them after miners are hoisted if any persons are still in the mine.

A series of five bills relating to the mine acts of the state has been introduced in the House by Representative Charles F. Beidelspacher, Lycoming County. One of these amends an act of 1903, creating the State Department of Mines, by providing for fees for examination and qualification of mine foremen and assistants in the anthracite mines. A second bill amends an act of 1901 by providing that it is the duty of the mine inspector to prosecute for violations of the mining law. The third measure provides for the appointment of boards of examiners to examine applicants for certificates of qualification as mine foreman, assistant mine foremen and firebosses in the bituminous coal mines of Pennsylvania and prescribes the qualifications, defining the powers and duties and fixing the compensation of the examiners. Another of the series is a bill amending laws governing the safety of persons employed in the bituminous coal mines. The fifth of this series of bills requires bituminous operators to pay the state the actual cost of foremen's reports and record books which are now furnished by the state.

Eight bills bearing on coal and mining made their appearance during the eleventh hour of the last day for the introduction of measures in the House. It is still possible to introduce legislation in the Senate. Among the bills introduced is one by Representative Richard D. Burns, which would **regulate the sale of anthracite,** fix a standard of clean coal and provide for inspection. **Coal taken from rivers would be taxed** for state purposes **at the rate of 20 per cent of the value** when recovered and dredgers would have to pay a license fee of $25 to the commonwealth under the terms of a bill introduced by Representative J. Ross Horne, Cambria County. Richard Aston, a Luzerne member of the House, sponsored a **bill providing that 50 per cent of the anthracite tax be dedicated to the state,** which now retains all it collects, **and that the other half go to the cities, boroughs and townships where anthracite is mined.**

Auditor General Samuel S. Lewis has announced that because there was a reduction of more than $1,000,000 in the expected revenue from the anthracite coal tax for 1922 and of more than $2,000,000 from the indicated annual yield under normal conditions **a revision of the 1922 reports made to his department by the anthracite producers will be made.** The reduction is indicated by a compilation of the anthracite coal reports for last year for which accounts are now being settled.

The Pinchot administrative code, which reorganizes the state government, **places the State Department of Mines in the Department of Labor and Industry,** making it the mining branch of that department. The code was introduced in the Senate recently. Section 1712 of the code gives the mining branch the same powers the Mining Department now has under existing laws. The examining boards of the Mining Department are placed under the Department of Public Instruction. Section 1309 creates a State Mine Inspectors' Examining Board, which takes over the duties of the Anthracite Mine Inspectors' Examining Board and the Mine Inspection Examining Board.

The House Judiciary General Committee has **reported out affirmatively the Burns bill which would make all coal companies public utilities** and therefore subject to the control of the Public Service Commission. The vote in favor of reporting the bill was 11 to 6. Representative Burns, Philadelphia, sponsor of the measure, appeared before the committee, which held a continued hearing on the bill. He said that coal prices should be regulated just as are those for gas, electric, water and steam service. Opponents of the measure a week prior had contended that coal is not a monopoly like the services the bill's sponsor referred to and that it could not be regulated in the same way.

State Senator P. F. Joyce, Luzerne County, has introduced in the Legislature **a bill modeled along the lines of the Kohler mine-cave law,** which was declared unconstitutional last year. It is designed to protect the lives and safety of persons residing over anthracite mines in cities, boroughs and first-class townships. The measure places in the hands of the chief of the Department of Mines the power to decide whether or not mining shall be carried on in the municipalities covered by the provisions of the bill. Violators of the act would be subject to a fine of $5,000 or imprisonment for a year, or both.

The Pennsylvania Fuel Commission has **rescinded its order of last September controlling deliveries of anthracite** for domestic consumption.

A four weeks' course in coal mining will be given at Carnegie Institute of Technology, according to an announcement from the institution, beginning June 25 and ending July 20. The object of the course is to prepare miners for the examinations of the State Department of Mines for positions as firebosses and mine foreman. At the completion of the work the miners will be awarded certificates by Carnegie Tech, and mine-rescue and first-aid certificates by the U. S. Bureau of Mines. At morning sessions the following subjects will be taught at Carnegie Institute of Technology: Mine laws and regulations, mine ventilation, mine gases, safety lamps, methods of working, mine explosives, timbering and haulage. On afternoons, at the Pittsburgh Experimental Station of the Bureau of Mines, the students will be instructed in mine rescue and first-aid training, coal-dust explosion demonstration at the experimental mine, permissible explosives demonstrations at the experimental mine, lectures on mine safety, etc.

TEXAS

The Texas & Pacific Coal & Oil Co. reports gross earnings of $7,316,287 in 1922, against $9,227,910 in the previous year. After payment of all expenses and reserves for depreciation there was left a balance of $2,077,736 available for the 8,448,048 shares of capital stock of $10 a share par value outstanding, or the equivalent of $2.45 a share. In 1921 the company reported net income of $2,077,519 after the same deductions, equal to $2.46 a share.

UTAH

The Columbia Steel Corp. has acquired title to 312 acres of coal land in Carbon County by a cash settlement of approximately $740,000 on the purchase contract. The property involved adjoins the Sunnyside coking deposits of the Utah Fuel Co. on the north and has been pronounced by experts to be good coking coal.

WASHINGTON

To promote greater co-operation among retail dealers and that they may understand the processes involved in the production of briquets, the **Pacific Coast Coal Co. was host to 150 outside dealers** March 22 on a sightseeing trip through its plants in the vicinity of Seattle. The trip concluded with a banquet at the Frye Hotel in the evening. Dealers from every section of the state were members of the party.

WEST VIRGINIA

Eight houses, the store and the mine office of the Soper-Mitchell Coal Co., operating at Scott's Run, in the Monongahela field, **were destroyed by fire** on March 24, and the tipple partly damaged, though not sufficiently to halt operations at the mine. The fire was started by an overheated stove in a dwelling occupied as bachelor quarters by six miners. A house belonging to the Diamond Fuel Co. also was destroyed. Only heroic work upon the part of the miners employed at the Soper-Mitchell plant saved the tipple from destruction.

A freight wreck at Eggleson Tunnel on the Virginian Ry. late in March caused **a total suspension of the movement of coal freight** for several days. Eighteen carloads of coal piled up in the tunnel and it was necessary to detour passenger trains over the Norfolk & Western, no attempt being made to move any freight.

Complete figures covering every phase of mining in West Virginia for the fiscal year ending June 30, 1922, though not so far printed, have been compiled by the West Virginia Department of Mines, the following table affording a summary of such mining activities in the state, for the period given (figures for coal representing gross tons and for coke net tons):

Counties in which coal is mined on a commercial scale	35
Firms operating on a commercial scale	888
Openings of all kinds subject to the mining law	1,381
Coal pick mined from commercial mines, tons	15,565,016
Coal machine mined from commercial mines, tons	54,623,187
Total tons of coal from commercial mines	70,188,203
Estimated tons of coal from small mines	700,000
Total tons of coal from all mines	70,888,203
Coal converted into coke, tons	296,151
Coke manufactured, tons	175,156
Total value of coal at the mines	$180,764,917.65
Total value of coke manufactured	$1,026.414.16
Value of a ton of coal at the mines	$2.55
Value of a ton of coke at the ovens	$5.86
Number of mining machines in use	3,434
Average number of coke ovens in use	750
Days mines were in operation	131
Days ovens were in operation	146
Pick miners employed in commercial mines	14,161
Machine operators and miners employed in commercial mines	44,070
Underground laborers in commercial mines	30,700
Outside employees connected with commercial mines	18,517
Coke employees	261
Persons employed at commercial mines and coke ovens	107,709
Persons killed	330
Persons injured non-fatally	542
Persons employed for each man killed	326
Persons employed for each man injured	199
Tons of coal mined in commercial mines for each fatality	214,813
Tons of coal mined in commercial mines for each non-fatality	127,100
Number of wives left widows	182
Number of children left fatherless	450
Acres of coal worked out	8,795
Tons of coal produced in commercial mines, per miner, pick and machine miners included	1,205
Average earnings of each pick miner, per year	$1,099.10
Average earnings of each pick miner per month	$91.59
Average price per ton of mining run-of-mine coal	$0.95

WISCONSIN

B. M. Ainesworth has been elected president of the **newly formed Valley Coal & Dock Co.,** 273 Broadway, Milwaukee. Other officers named were R. L. Clements, general manager; F. F. Klegel, treasurer; J. F. Sweeney and F. H. Baker, directors. The new company, which has absorbed the old Valley Coal Co., began operations under the new organization on March 31 with a capital of $250,000.

The Industrial Coal & Dock Co., Milwaukee, 1,000 shares common stock without par, has been incorporated by J. Gilbert Hickox, Leo Mann and Walter C. Ferris.

WASHINGTON, D. C.

Those in attendance at the recent **annual meeting of the Joseph T. Holmes Safety Association,** held in Washington, were Dr. H. Foster Bain, Director U. S. Bureau of Mines and president ex officio; Edgar Wallace, American Federation of Labor; Dr. David T. Day, American Mining Congress; E. H. Denny, J. O'Leary, United Mine Workers of America; Dr. George K. Burgess, American Society for Testing Materials; Major M. J. Shields, American Red Cross; Dr. David White, National Academy of Sciences; John H. Finney, American Institute of Electrical Engineers; Gen. W. H. Bixby, American Society of Mechanical Engineers; George S. Rice, American Institute of Mining and Metallurgical Engineers; J. W. Paul, Mine Inspectors' Institute; Dr. J. J. Rutledge, Geological Society of America; Dr. Andrew Stewart, American Chemical Society; F. J. Bailey and Dr. R. B. Sayers, U. S. Bureau of Mines.

The U. S. Navy will open bids April 18 at noon for the following quantities of **bituminous or semi-bituminous coal** for ships: 12,000 gross tons at New York, delivery from May 1, 1923, to June 30, 1924; 3,000 gross tons at Philadelphia, delivery from July 1, 1923, to June 30, 1924; 425,000 gross tons at Hampton Roads, delivery from July 1, 1923, to June 30, 1924; 50,000 gross tons at Baltimore, delivery from July 1, 1923, to June 30, 1924; 200,000 gross tons at Sewalls Point, Va., 50,000 tons to be delivered prior to July 1, 1923, and remaining 150,000 tons prior to Nov. 1, 1923.

CANADA

Harvard Stutchbury, trade commissioner for Alberta, is in Toronto on a mission for the opening up of a market for Alberta coal in Ontario. The Ontario government has appointed a committee to receive and distribute shipments of Alberta coal during the coming season and **a demonstration of its burning and treating qualities will be given** as early as possible under the direction of G. R. Pratt, fuel engineer for the Alberta government.

A plan for the exportation of coal from Mexico to Canada which would be beneficial to both countries has been submitted to the Fuel Commissioner at Ottawa by L. F. Bustamente, Mexican commercial agent in Canada.

Mining and Loading Machine. N. D. Levins, Columbus, Ohio, assignor to the Jeffrey Mfg. Co., Columbus, Ohio, 1,437,526. Dec. 5, 1922. Original application filed Jan. 13, 1917; serial No. 142,324. Divided and this application filed Jan. 20, 1919, serial No. 272, 115; renewed March 2, 1922, serial No. 540,572.

Coal Screening and Washing Machine. Wm. F. Martin, Wormleysburg, Pa.; 1,437,669. Dec. 5, 1922. Filed May 18, 1922; serial No. 561,978.

Coal Screening and Washing Machine. Wm. F. Martin, Harrisburg, Pa.; 1,438,125. Dec. 5, 1922. Filed May 18, 1922; serial No. 561,979.

Obituary

C. S. Williamson, formerly of the Meade-Morrison Manufacturing Co., who had a great deal to do with the designing and installation of modern coal machinery at Milwaukee and other leading upper lake ports, died in Chicago on Saturday, March 31, 1923.

Albert H. Tracy, 83 years old and active in the city coal trade of Buffalo, died on April 3, after a short illness. He was long in the trade, being superintendent of the Delaware & Hudson water-shipping trestle several years, till the company went out of business at Buffalo. He was well known, an active worker in church and in general benevolent enterprises. He leaves a wife and three daughters. His son and namesake, manager of the Tracy Coal & Wood Co., died several years ago.

Traffic News

On account of accumulation **an embargo was placed April 6 by the New York Central R.R.** against the acceptance of all carload and less carload freight from connections at 60th Street or 68th Street, New York City, Weehawken, National Junction, or Harsimus Cove, for points on or via the Boston & Albany R.R., except livestock, perishable freight, flour, deeds for livestock, anthracite coal, fertilizer or fertilizer materials including agricultural lime, pulverized lime, limestone, phosphate rock, field and garden seeds when in packages, sacks or bags, spraying materials, spraying machinery, agricultural implements required for planting purposes, Boston & Albany Railroad fuel, material and supplies, freight consigned to offices of the U. S. Government and shipments covered by permits issued by C. J. Brister, assistant vice president, New York Central Lines, Chicago, Ill., or G. C. Woodruff, general freight agent, New York Central R.R., New York City,

On account of an accumulation **an embargo** was placed March 31 by the **Philadelphia & Reading Ry. against all carload freight** destined to 22nd and Allegheny Ave. Station, Philadelphia, Pa., consigned to John J. Davies & Co., R. D. Letterle, F. R. Philip and Edward Morris.

According to well-authenticated reports, **the Virginian Ry. will extend its line** from Elmore, W. Va., down the Guyan River to or near Pineville, in Wyoming County, W. Va. In fact **both the Virginian and the Chesapeake & Ohio have made surveys of proposed routes** along the river and both have obtained rights of way that conflict at some points for some distance below Pineville. A survey of the proposed route and an application to construct the railway have been filed with the Public Service Commission at Charleston, and it is understood that the Virginian will soon invite bids for the construction of the proposed extension. There also is the possibility that the company will extend its line beyond Pineville and traverse Wyoming and Logan counties to a terminal near Huntington.

Heavy coal movement last year was a primary factor in Norfolk & Western Railway Co., **gross revenues of $90,352,887, the largest in the road's history**, according to the report for 1922. In 1921 gross amounted to $80,718,802, while operating expenses rose from $64,346,857 to $68,052,304 last year. Balance available for dividends, after deductions for rentals, interest and miscellaneous charges totaled $14,554,989, equal after preferred dividends to $10.66 a share on the $127,826,900 outstanding common stock. In 1921 net was $10,043,181, or $7.50 a share on the $121,519,700.

The Norfolk & Western R.R. has ordered 25 Mallet locomotives for use in all divisions of its lines, principally in hauling coal. These engines, weighing 536,000 lb. and having a pulling capacity of 7,000 tons, will aid in taking care of the lake trade this season.

The Interstate Commerce Commission has set June 14 as the date on which **to hear oral arguments in the following coal cases**: Illinois Coal Traffic Bureau vs. Chicago & Northwestern R.R.; Northwestern Coal Dock Operators' Association vs. Chicago & Alton R.R.; C. Reiss Coal Co. vs. Ahnapee & Western R.R.; Traffic Bureau of the Sioux City Chamber of Commerce vs. the Baltimore & Ohio R.R.

The following embargoes have been cancelled: Coal via New York Central for United Hudson Electric R.R. Co., Catskill, N. Y.; Bituminous coal via New York Central for Superior Fuel Co., at all New York City stations; all freight via Boston & Maine for Cunningham Grain Co., Oak Grove, Mass.; all freight via New York Central for Staten Island Rapid Transit Railway.

On account of accumulation and to prevent congestion due to inability of the N. Y., N. H. & H. R.R. to take from B. & A. R.R. currently cars for delivery in their Boston switching limits **an embargo was placed April 3 by the Boston & Albany R.R.** against all carload freight from connecting lines at Albany, West Albany Transfer and Rensselaer, N. Y., intended for public deliveries or private sidings on the N. Y., N. H. & H. R.R. at Boston, Mass., Army Supply Base, Bird Street, Commonwealth Pier No. 5, Dudley St., Harvard St., South Boston Terminals Boylston St., Forest Hills, Harrison Square, Roxbury, Mass., when routed via Framingham or Boston, Mass. No exceptions and all outstanding J. O. Halliday permits covering cars for those destinations will not be honored.

On account of line being discontinued **an embargo was placed April 3 by the Bangor & Aroostook R.R.** on all shipments, carload and less carload, destined from Works, North Brownsville and Gould Siding, Maine.

On account of advices received from the Central New York Southern R.R. dated April 2, 1923, as to possible supension of operation effective at once, **The New York Central R.R. embargoes** all carload or less carload freight consigned to points on the Central New York Southern R.R., except shipments tendered by shipper and accepted by the railroad on the basis of "at shipper's risk on account of failure of connecting carrier at Auburn to accept and transport beyond New York Central R.R."

The Alexandria Paper Co., of Alexandria, Ind., has **attacked the rate on bituminous coal from Springfield, Ill., to Alexandria.**

Batchelor & Barlow, of Sharpesville, Ind., have filed **complaint against the rate from Springfield to Sharpesville.** Similar complaints have been filed against the rate from Springfield to various Indiana points.

The Consumers' Fuel & Ice Co., of Watertown, S. D., has **complained against the rate on coal from Herrin, Ill., to Watertown.**

Joseph Bancroft & Sons, of Wilmington, Del., has filed a **complaint based on rates from certain producing points in Pennsylvania to Wilmington.**

Stockholders of the **Hocking Valley R.R.**, meeting at Columbus, Ohio, April 3, **elected the following directors:** O. P. and M. J. Van Sweringen, C. L. Bradley, J. J. Bernet, W. A. Colston, Otto Miller, J. R. Nutt, J. B. Zerbe, all of Cleveland; F. R. Hunting, Columbus; Jeremiah Milbank, New York City; Thomas J. Davis, Cincinnati, and W. J. Harahan, Richmond, Va.

On account of accumulation **an embargo was placed March 29 by the New York Central R.R.** against all freight consigned, reconsigned or intended for the Rogers Milk Corporation, Boonville, N. Y.

An embargo placed by the **Susquehanna & New York R.R.** against freight destined to points on the Hillsgrove Tram R.R. **was entirely cancelled** March 29.

Certain shipments of coal from Higginsville and Macon, Mo., and Cornell, Kan., to Argentine, Kan., **are found to have been overcharged** in a tentative report made to the Interstate Commerce Commission by its examiner. The overcharge was found to have been 40c. per net ton.

A report by examiner Carter of the I. C. C. finds that the **Cambria Steel Co.**, of Johnstown, Pa., **was charged an unreasonable rate on the movement of 61 cars of coal** from Pennsylvania points to Johnstown. The rates were found unreasonable to the extent that they exceeded commodity rates subsequently established.

The Interstate Railroad Co., now completing a new line running from Norton, Va., to a connection with the Carolina, Clinchfield & Ohio system, has asked for authority **to issue $1,057,756 in new capital stock**, which it purposes to sell at par, the funds to be used to complete its building project, to pay off existing indebtedness, and to reimburse the road's treasury for expenditures made upon it.

The Kanawha & West Virginia R.R. and the New York Central have applied to the Interstate Commerce Commission for authority **to construct an extension** of the line of the former road from its present terminus at Swiss, eastwardly up the Gauley River to the mouth of Meadow River, a distance of twenty miles, thence southwesterly up Meadow River to a connection with the Sewel Valley R.R., near Nallen, a distance of nine miles. It also is proposed to build a branch line at a point eight miles above Swiss to extend northwestwardly up Peters Creek to Line Creek, a distance of four miles.

Association Activities

Hazard Coal Operators Association

The Executive Committee of the Hazard Coal Operators Association met at the Gibson Hotel in Cincinnati on April 3 and went over many items that were of an association nature—among which was car allotments that would be expected from the Louisville & Nashville and traffic conditions and betterments that had been promised by that line. Informal discussions were made after the meeting by members concerning the pooling of coal from Hazard for handling over the docks at the Head-of-the-Lakes. Intimation was given that it might be possible to lease dock space or forward coal to dock concerns for handling on a straight unloading cost plus a selling commission.

Cincinnati Coal Exchange

At the regular monthly meeting and luncheon of the Cincinnati Coal Exchange, April 5, Thomas L. Lewis, secretary of the New River Operators' Association, was the speaker. Mr. Lewis declared that "politicians were the curse of this country" and that their meddling with business caused distress to the consumers. He lit into the Interstate Commerce Commission and said that its members were only human. Lewis said that he feared that the **findings of the President's Coal Commission would result in the formation of a permanent coal commission** modeled along the line of the Interstate Commerce Commission "And then God help this country."

Coming Meetings

National Association of Purchasing Agents will hold its eighth annual convention and Informashow at Cleveland, Ohio, May 15-18. Convention headquarters, room 219, Hotel Winton, Cleveland.

The National Association of Manufacturers will hold its 27th annual convention at the Waldorf-Astoria, New York City, May 14-16.

New England Coal Dealers' Association will hold its annual meeting at Providence, R. I., June 13-15. Secretary, C. R. Elder, Boston, Mass.

National Retail Coal Merchants' Association will hold its sixth annual convention June 25, 26 and 27 at Scranton, Pa., with headquarters at the Hotel Casey. The registration fee of $15 will include all meals except breakfast, transportation to and from the mines which will be visited, and the banquets. The only other expenses to be incurred will be hotel room and transportation to and from Scranton. Executive secretary, J. E. O'Toole, Philadelphia, Pa.

National Safety Council will hold its twelfth annual safety convention at the Buffalo Statler Hotel, Buffalo, N. Y., Oct. 1-5. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

International First-Aid and Mine-Rescue meet will be held Aug. 27-29, at Salt Lake City, Utah.

American Institute of Electrical Engineers will hold its annual convention June 25-29, at Swampscott, Mass. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

Coal Mining Institute of America will hold its annual meeting Dec. 19, 20 and 21 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Chamber of Commerce Building, Pittsburgh, Pa.

The Virginia Coal Operators' Association will hold its annual meeting on April 21 at Norton, Va. Secretary, G. D. Kilgore, Norton, Va.

International Railway Fuel Association will hold its spring convention at the Hotel Winton, Cleveland, Ohio, May 21-24. Secretary-treasurer, J. G. Crawford, Chicago, Ill.

The American Mining Congress will hold its twenty-sixth annual convention in conjunction with the **National Exposition of Mines and Mining Equipment**, Sept. 24-29, at the Milwaukee Auditorium, Milwaukee, Wis. Secretary, J. F. Callbreath, Washington, D. C.

Indiana Retail Coal Merchants' Association will hold its annual meeting April 25 and 26 at the Claypool Hotel, Indianapolis, Ind. Secretary, R. R. Yeagley, Indianapolis, Ind.

American Society for Testing Materials will hold its annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, N. J., beginning June 25 and continuing throughout the week. Secretary, E. Marburg, Philadelphia, Pa.

The Colorado & New Mexico Coal Operators' Association will hold its annual meeting June 20 at Denver, Col. Secretary, F. O. Sandstrom, Denver, Col.

The Electric Power Club's annual meeting will be held at the Homestead, Hot Springs Va., June 11-14. Executive secretary, S. N. Clarkson, Cleveland, Ohio.

National Foreign Trade Council will hold its annual conference May 2-4 at New Orleans, La. Secretary, O. K. Davis, 1 Hanover Square, New York City.

The eleventh annual meeting of the Chamber of Commerce of the United States will be held in New York City May 7-10.

National Coal Association will hold its sixth annual convention June 19-22 at Atlantic City, N. J. Assistant secretary, C. C. Crowe, Washington, D. C.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 23 NEW YORK, APRIL 19, 1923 Number 16

A Battle of Publicity

ABANDONING for the time their usual forceful tactics for promoting the extension of their organization, the organized mine workers have turned the guns of publicity on the non-union coal operators. Beginning some months ago with the demand that all coal fields be unionized, they have lost no opportunity to assert that it is the fact that some operators have managed to stay without their fold that has been responsible for the ills of the coal industry. This summer it is to a battle of words rather than of bullets.

Colonel Stimson's arraignment, on behalf of the Special Committee of Bituminous Coal Operators, of the policy, purpose and methods of the United Mine Workers so far has brought forth nothing further in reply than an attempt to make light of the charges because they were prepared by two lawyers. Now there may be a deal of difference between a statement prepared for the operators by lawyers and one prepared for the miners' union by a newspaperman, and the difference may be due to the fact, as particularly stressed by the union's "release" of April 12, that the lawyers are highly paid. That fact seems to distress many.

At any rate, there has been nothing since the war that has served to solidify the ranks of the soft-coal operators as has this challenge of the union. Changing from a policy of defense to one of aggressive offensive, the operators' association has taken on new life. Union as well as non-union operators have rallied to the support of the Special Committee, of which John C. Brydon is chairman, for the committee is bent on taking the fight into the enemy's camp, via the same route selected by the union, that of publicity.

Causes of General Goethals' Troubles

GENERAL GOETHALS, in his official report to Governor Smith at the close of his service as Fuel Administrator for New York State, succinctly summarizes the situation that faced him. The New York law under which he functioned gave him all the authority and funds that could have been bestowed by a state legislature. General Goethals found, however, that the State of New York could grant him no power over coal mines in another state or over coal moving in interstate commerce, which meant all the coal that came into his jurisdiction. His control over prices was confined to retail dealers' margins, since he could in no wise influence the mine price or the freight rate. His function with respect to distribution was entirely that of seeing that after the coal reached the dealers' yards it was equitably apportioned among the household customers.

Because the production of coal is not interstate commerce and because shipments across state lines are, a State Fuel Administrator dependent on outside sources cannot increase his share of the total by depriving others of coal going to them. General Goethals found that he lacked authority to divert shipments within his state, that he could not speed up the movement of his own coal, could not fix prices to dealers, or control the quality of coal shipped to him. He complains that the Federal Fuel Distributor had no authority, which is entirely true, and that the Interstate Commerce Commission, which presumably had some authority under the federal law, was a "quasi-judicial body, not accustomed to executive action." He might have added that, with respect to his own situation, the Interstate Commerce Commission did not always exercise what measure of authority it had in accordance with the recommendations of the Federal Distributor, as suggested by the act of Congress.

What the General has to say with respect to the lack of authority conferred on the federal officials is quite true, but he might have accompanied it by the acknowledgment that in the act creating the Federal Fuel Distributor Congress gave him all the power, authority and jurisdiction it could under the limits imposed by the Constitution. It is particularly significant that after reciting the steps taken to insure the necessary use of substitutes for anthracite, he admits that such trouble as was experienced in New York State was occasioned by non-compliance with his orders. He says: "Difficulty was experienced in securing full compliance [with orders that substitutes be used], and in most communities where shortages were reported or crises threatened, investigation disclosed that such conditions were due to non-compliance with this order."

Which brings us to the heart of the matter. All of General Goethals' troubles and those of Mr. Woodin before him, as well as those of fuel administrators in other states, were due to shortage of anthracite. Had there been sufficient hard coal there would have been no fuel administrators, no high prices, no impure coal and rock delivered to consumers. But the country was short some thirty to forty million tons of production and had to face the winter with but 60 per cent of requirements for consumption. No amount of price fixing and regulation of distribution could, or ever can, make more tons of coal. There was non-union soft coal to substitute for union soft coal not produced last summer, but there was no non-union hard coal. And after the strike was settled there was soft coal of all kinds to make up the deficiency in anthracite, but people did not take kindly to its use, therefore the most of the trouble.

Plainly enough if this country can find no way to curb the power of the United Mine Workers and continues to submit to such unwarranted suspensions of mining as characterized the hard-coal strike of 1922, then, but not until then, is it time to discuss the technique of governmental regulation of price and distribution. Complete elimination of the comparatively small quantity of "fireproof" coal distributed, repression of the 5 per

cent of "higher price" tonnage reported by General Goethals and theoretically perfect distribution of available coal would not have relieved the shortage or obviated the use of substitutes. All these things, irritating as they were, were as nothing compared to the fact that because the United Mine Workers chose to exert their full "economic strength" they called a strike in the anthracite field and thus deprived householders of millions of tons of hard coal.

Reservoir Sump Systems an Operating Economy

BIG power bills are bringing operators to a recognition of the importance of having large sumps. A big underground reservoir is an assurance against the drowning out of the shaft in case of accident to the pumps or pipes, power failure or an excessive inflow of water. It is a cheap substitute for the large and expensive machinery that the power station, public or private, must introduce to take care of peak loads. Cheaper by far as a rule would be a few million gallons of storage than a few hundred kilowatt-hours of capacity. To avoid paying the latter the power company penalizes the operator, who, not having storage capacity, is obliged to add pumping to his other loads during the busy hours of the day.

In this issue of *Coal Age* an article describes the reservoir or sump system in the Isabella mine of the Hecla Coal & Coke Co. It is only one of many large sumps. Its interest lies in the utilization of airways for water storage and the problems thereby confronted and solved. Another large sump system is that in Eureka No. 25 mine of the Berwind-White Coal Mining Co., at Windber, Pa., where the reservoir lies in the major axis of the Wilmore basin and has an area of eight to ten acres. Water flows to it from mines Nos. 35, 36, 37, 40 and 42.

This company pumped 111,000,000 gallons of water in December of 1921, about 3,600,000 gallons per day. As the sump fills in two days, the capacity is twice that of the daily accumulation, or 7,200,000 gallons. The pump-room is equipped with three 4,000-gallon centrifugal pumps which lift against a 330-ft. head in an 18-in. main and are driven by 500-hp. induction motors. Only two of these units are operated on any one night and consequently it takes from eight to nine hours to empty the sump.

In the early days of steam as a direct agent of power at the mine the men behind the shovels in the boiler room were the instruments by which the consumption of power was measured. If the steam failed to do what was required of it, the firemen were supposed to be flagging on the job or stoking badly. Sometimes the firemen by a burst of energy could carry the load over its peaks, but often the pumping load was so heavy that the other loads had to be reduced to permit the pumps to run.

Now, the load is more accurately ascertained. When men begin to measure and record, then comes regulation. As soon as a co-operating factor like the power station comes into the business, an attempt to place responsibility results in better performance, and both parties endeavor to arrange that mutual accommodation shall be rewarded by mutual advantage. Thus arises the lowered rate for off-peak service, which is a concession of the power corporation of which the frugal operator should take full advantage.

Strange to say, many operators for many long years perseveringly pumped water during busy hours because they lacked storage capacity that would enable them to do otherwise. They did not realize the loss because they had no figures to show them what they were losing. Now that power is purchased the doubt as to the loss is gone. The facts can be no longer hidden and the change is almost automatic.

With continuous pumping the pumps need continuous superintendence. When all the work is done in a short portion of the day the wage charge is reduced from one-third to one-half. Furthermore, where the water flowing to the sump contains suspended matter the large sump provides a chance for the silt to settle, thus saving the impeller and the case of centrifugal pumps from wear and possible clogging and the cylinders and plungers of reciprocating pumps from abrasion. Moreover, with clear water the valves of these pumps will function without interruption.

FREQUENT AND WIDESPREAD REPORTS of wage increases in industry have marked the past three months. These increases have come mainly in the textile, clothing and steel industries. When considering these upward changes in wage rates it is well to have in mind that they are taking place in industries in which wages were deflated in 1921 and that the wage levels after these present increases are even yet generally below the peak of war and post-war scales. The recent advance of 12½ per cent by the Amoskeag Mills, for instance, leaves wages 2 per cent below the war peak, it is stated.

In the coal industry, on the other hand, union wages have not receded from the post-war peak, which is well above the war-time levels. In other words, wages that were lowered during the slump of 1921 are now coming back as industry gains in activity. A shortage of labor is reported more or less generally over the country, save in the soft-coal industry. There is, in consequence, a distinct trend toward the further development of mechanical aids to production to offset high labor costs and labor shortage. This is true also in coal mining, where there is now under way intensive development of mechanical loading machinery and of other devices for increasing output per man and for lowering the labor cost in producing coal.

SOUTH AFRICA'S COAL IS MORE VALUABLE THAN ITS DIAMONDS judging by the report of the government mining engineer for the first eleven months of 1922. The output of the Union of South Africa for that period was 8,907,576 tons valued at £3,196,037, whereas the diamond output for the same period brought only £1,995,513. Now that coal shipments are starting from South Africa for a long haul across the equator to Germany, the coal production of the tip end of the black continent attains a little worldwide attention. At the twenty-second geological conference held in Canada it was estimated that the South African coal deposits totaled about fifty billion tons.

THE CHIEF TROUBLE with the country just as present seems to be too many authorities and not enough authority. —*Baltimore Sun.*

FRANCE CONTROLS THE PITHEADS. It remains to be seen whether she can control the square heads.—*Norfolk Virginian-Pilot.*

Large Sump and Night Pumping Lower Peak Load When Electric Power Displaces Steam at Isabella

Reservoir Holds More Than a Million Gallons—Sump Near Shaft Sealed with Gunite—Stoppings, Dams and Buried Pipe Mains Keep Water from Tracks —High-Voltage Dangers Underground Reduced by Suitable Construction

By Alphonse F. Brosky*
Pittsburgh, Pa.

DURING the shutdown of 1922 the Hecla Coal & Coke Co., a subsidiary of the Hillman Coal & Coke Co., made many improvements to the Isabella mine, at Isabella, Pa. This mine has two hoisting shafts both of which are located a short distance from the bank of the Monongahela River. Among the improvements that should be mentioned were the substitution for steam-driven machinery, of electrical equipment operated by purchased power. At the same time a large underground sump was constructed under unusual difficulties near these two shafts. This was done mainly for the purpose of permitting the pumping of water during the night and thus reducing the peak load to a level which would not draw a penalty.

In order to familiarize himself with the location, elevations and other details of the sump the reader should study Fig. 1, which shows a section of the mine layout. From No. 2 shaft, up which the water is pumped, the sump system runs northeastward in a return airway, known as No. 2 aircourse, for a distance of about 725 ft. it then crosses the main entries to the west by a passageway driven expressly for that purpose, and occupies a portion of No. 1 return airway and the first two sets of the butt headings driven to the west. All the sumpage is in roadways or airways, except where connecting waterways have been constructed. No rooms are available for the storage of water.

Sump Will Take Water from Two Mines

For the purpose of hauling coal from Tower Hill Mine No. 2 to the river for shipment by water that operation which is owned by another subsidiary of the Hillman Coal & Coke Co., is connected underground with the Isabella Mine. In order to provide for this additional tonnage whenever it is decided to raise it in the manner indicated the mine is furnished with two hoisting shafts. The water already is handled from the one mine, consequently the sump must be large enough to hold the water from both mines, that from the Tower Hill No. 2 Mine being pumped to the sump.

Though it is estimated to hold at least 1,000,000 gallons the exact capacity of the sump has not been determined. It is so large, however, that it is expected that it will hold all the water likely to accumulate over a period of not less than 72 hours. The superintendent tells me, however, that from his knowledge of this mine he doubts whether the stage will rise above 654 ft., which is 2 ft. below the flood stage for which provision has been made.

Because the elevations of the bottom in the vicinity of the shafts are such as to facilitate the construction of a sump with a minimum of excavation, a new pumproom was built at *A*, in a breakthrough driven from No. 2 aircourse to No. 1 shaft. As the distance to No. 2 shaft is short, the water readily could be discharged through the upcast compartment of that shaft, and as this compartment is an upcast all danger of freezing was removed. Consequently no borehole had to be drilled to the surface. But to drain all the water in the sump to a suction well at the pumproom, the underclay had to be lifted on No. 2 aircourse, as reference to the elevations of the bottom will make apparent. The bottom of the aircourse before excavation was at an elevation of 660 ft. near No. 2 shaft and only 654 ft. at the breakthrough where the system crosses to the west.

Again referring to the elevation of the bottom in the vicinity of this crossover point, it will be noted that a natural shallow basin lay there, and it was to this basin,

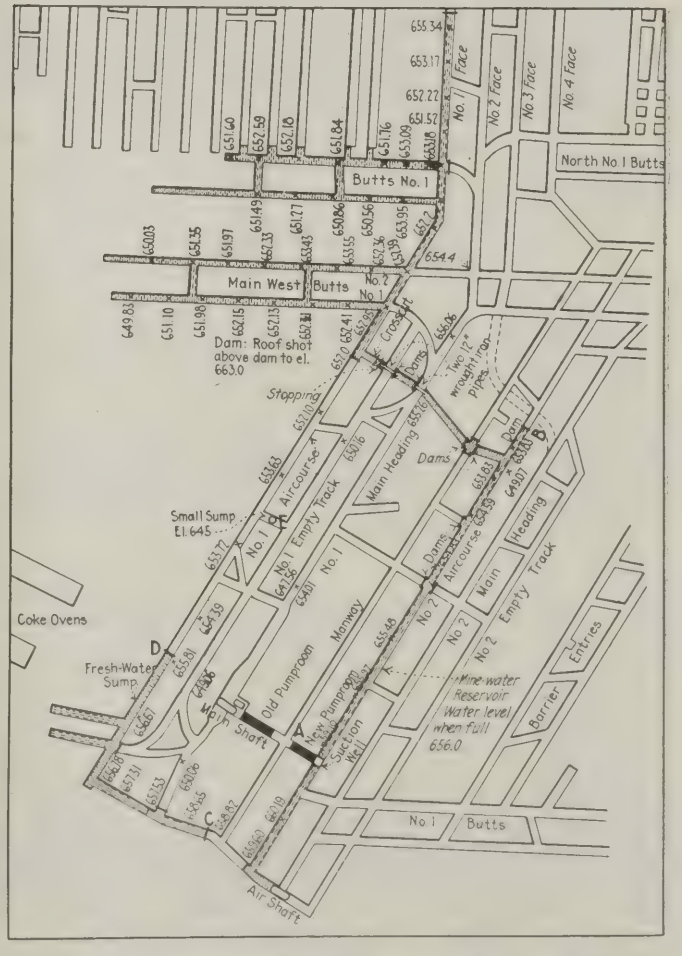

FIG. 1—EXTENSIVE SUMP AT ISABELLA SHAFT

In order to get space for the storage of water without weakening the pillars around the shaft an excavation was made along No. 2 air course and provision was made to store water on roadways a long way from the shaft. The sump had to cross a manway and two haulways. In order to protect the shaft further the excavation was gunited.

*Assistant editor, *Coal Age*.

before the present sump was constructed, that the suction line extended, coming from the old pumproom adjoining No. 1 shaft which housed the steam-driven pumps. This basin was so small that only by keeping these units in continuous operation could the main bottoms be kept free of water. In order that the space may be utilized as a waiting room the steam equipment will be removed from the old pumproom.

By taking up bottom to an elevation of 651 ft. in No. 2 aircourse, the management calculated that, what with the storage afforded by the butt headings to the west, the sump system would be adequately large. Accordingly the bottom was lifted beginning at *B*. After excavating to an elevation of 651 ft. a soft bed of clay was encountered which dipped slightly toward No. 2 shaft, greatly facilitating the work. The cut increased from a depth of 3 ft. at *B* to a depth of 10 ft. near No. 2 shaft, where the bottom level of the ditch is about 650 ft. Thus the bottom of the sump sloped gently southward toward the shaft.

Holes for blasting were drilled horizontally by an electric drill in the soft bed of clay, giving a more effective lift to the shots. Above this soft material were shale and hard clay which could not be penetrated as readily by holes drilled in a vertical plane. The saving in drilling and blasting and the added storage space warranted the additional mucking caused by reason of a larger cut.

Fear was entertained that the clay might cut under the coal and so weaken the pillars on which No. 2 shaft and its bottom relied for protection. It was feared also that the shaft might settle as a result of the softening of the clay by water. Consequently gunite was placed on the exposed surfaces below the coal, thus sealing the water in the sump from all the clay surfaces along the entire main sump heading. Altogether 1,944 sq.yd. of gunite was applied to a thickness of 1 to 1½ in. and at a cost of $1.03 per square yard. Only in a few spots was it necessary to use a wire mesh for reinforcement. Where the main sump heading is deepest ¾-in. weep pipes were used to let in from behind the gunite facing whatever water could not be conveniently shut out.

So far the work has shown no signs of failing in the year that has elapsed since its completion. It might well have been feared that squeezes, no matter how inoffensive, would result either from the swelling of the clay or the squeezing of the strata consequent on mining and that these might displace the gunite, but appar-

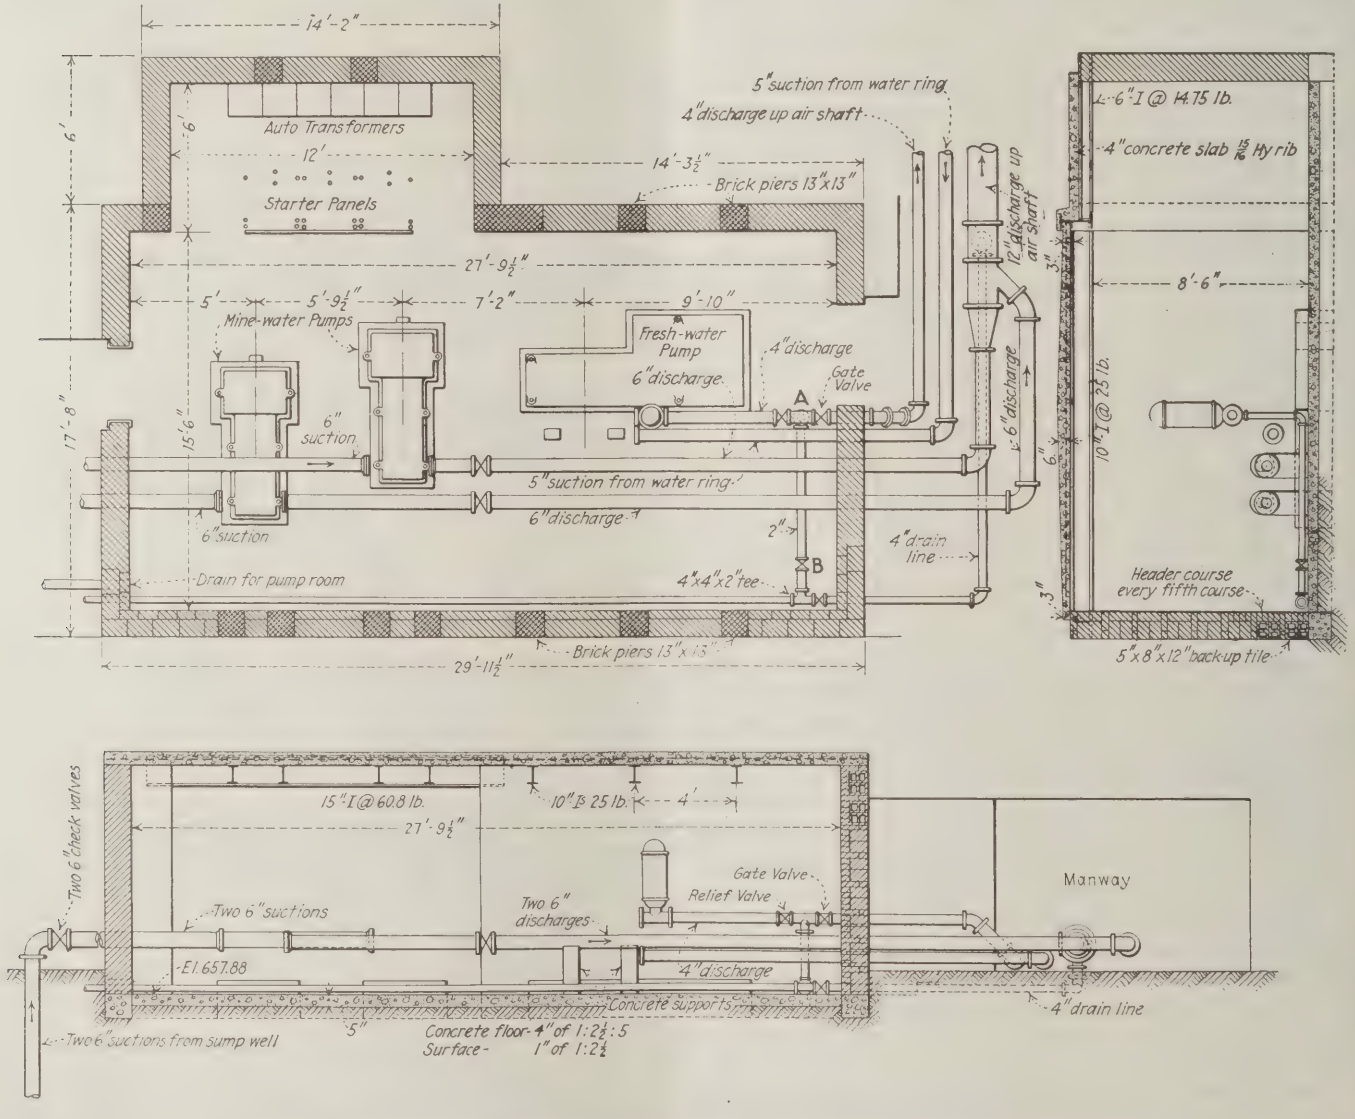

FIG. 2—PUMPROOM AND PUMP CONNECTIONS WITH PROVISIONS FOR PRIMING

In laying the foundations excavations were made to rock that might be expected to remain unaffected by the softening action of water and air. Underground, the foundation material may not have been subjected to such weathering actions and the present condition of a foundation bed may be not a correct index to its future condition as is the case with surface materials. The floor in this pumproom has been made part of the foundations. From this pumproom is discharged both dirty mine water and clean water, from the water ring, that water being stored in a separate sump located not far from the foot of the shaft.

ently the swelling action was wholly eliminated by the way the water was sealed off from the clay. As for the imperceptible squeezes resulting from the weight of the strata the panels of gunite possess sufficient flexibility as cantilevers to withstand the thrusts normal to them; or, if that is necessary, they can be given greater strength by the use of a reinforcing mesh. The success achieved on this job moved the Snowdon Coke Co. to gunite a sump in a near-by mine which holds 500,000 gallons of water.

To carry the sump system, which lies in the path of the return air, across the haulageways and fresh-air entries it was necessary to erect many brick stoppings and concrete dams. These dams rise to an elevation of 656 ft., or 1 ft. above the maximum water stage. Water which collects in the sump headings to the west is carried across the manway on the No. 2 side and across the two haulageways on the No. 1 side by sets of two 12-in. wrought-iron pipes which are buried beneath the entries they cross and beneath the stoppings that were erected to prevent the air from wandering from its determined course. These pipes are buried several feet below the entries, which provision, together with the tight stoppings, prevents the air in one entry from short-circuiting into another in which the air is traveling in the opposite direction.

No. 1 aircourse and the butt headings turned west, which form part of the sump system, required little conditioning. Dams had to be erected, however, and the roof had to be shot where these dams were located, so as not to restrict the airway. The bottom, also, had to be given a general cleaning. The bottom was taken up at a few points to establish the mean elevation at about 652 ft. Thus this area will hold a runoff to a depth of about 3 ft. whenever a maximum stage is reached, and consequently more than two-thirds of the entire storage capacity is developed here.

Fresh-Water Sump Holds Water for Town

As might be expected, the strata near the river discharge into the rings of the No. 2 shaft a moderate quantity of water, so pure indeed as to be suitable for town use. This water is piped to a fresh-water sump lying between dams *C* and *D* (see Fig. 1). The overflow from this fresh-water sump falls from the dam at *C* into the mine-water sump, which lies at a lower level.

Some people might look askance at supplying water from an underground source for town use, but under conditions such as exist here there is little to fear. Inasmuch as the fresh-water sump seals off that which might be strictly termed mine water and as the undesirable acids and salts in the wetted sides of the sump have long been removed by solution, the fresh water coming from the shaft rings and stored in this sump is the equal of any spring water in the region. As an added precaution it occasionally is treated with lime.

Thus is care taken of practically all the water in the Isabella and the Tower Hill No. 2 mines, though, of course, small pumps have to be used for gathering. Mine water from the main bottom in the vicinity of No. 2 shaft drains directly to the big sump. Water which gathers in the sump of No. 1 shaft, that which finds its way to a small sump at *E* and that which collects in a swag on No. 1 empty track are pumped to the big sump by a 6x8-in. piston pump which is driven by a direct-current motor. This unit is housed in the old pumproom adjoining No. 1 shaft.

The walls of the new pumproom are 13 in. thick and consist of brick and back-up tile. However, where the wall has to support crossbeams, solid brick pillars 13 in. square are erected in the walls. These crossbeams are 10 in. high and of I cross-section where they span the main building but only 6 in. where they cover a side extension of the pumproom. To support the 10- and 6-in. beams where the extension breaks the continuity of the wall, a 15-in. beam is laid across the pillars. The solid brick piers have been introduced into the body of the wall so as to give adequate support to this roof system.

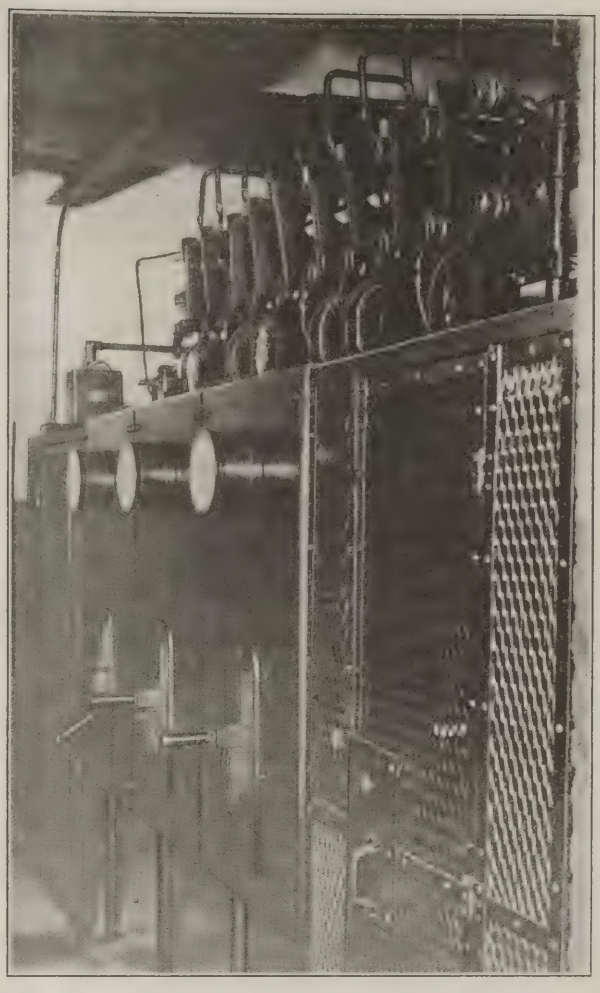

FIG. 3—STARTER PANEL FOR MINE PUMPS

A cable carrying a 2,300-volt current is brought through the wall behind the board to disconnecting switches and thence through oil starting switches to the motors. Nothing over 110 volts makes direct connection with the switchboard, the frame of which is grounded so as to afford the operative a further safeguard against shock.

The details of the design can be seen in Fig. 2. Entrance is gained to the interior through a door made of $\frac{3}{16}$-in. steel plate reinforced by riveted angles and channels. The pump foundations are carried to a solid footing by concrete piers and the floor is made part of these foundations.

The roof slab is of concrete reinforced with expanded metal and varies in thickness from 3 to 6 in. The upper flange of the 15-in. beam already mentioned, which otherwise would be subject to corrosion because of its inaccessibility for painting, is enveloped in concrete. This practice should be adopted in all work where steel and concrete are employed in the manner described. All other steel beams lie below the roof slab where they are accessible for painting and sheltered from roof water.

Mine water is pumped from the big sump up No. 2

airshaft against a head of 138 ft. by two 750-gallon single-stage centrifugal pumps driven by 60-hp. squirrel-cage motors. The 6-in. discharge lines from these two units connect by means of a Y to a 12-in. line which is located in the shaft. The 6-in. suction lines from the centrifugal pumps are provided with check valves as indicated in Fig. 2 and lead to a 10x12-ft. concrete suction well 8 ft. deep in the main sump heading adjoining the new pumproom.

Water for town use coming from the fresh-water sump is pumped up the same shaft against a head of 403 ft. to a reservoir tank on a hill by a 150-gallon plunger-type triplex pump which is driven by a 50-hp. squirrel-cage motor. This pump has a 5-in. suction which taps the little sump through the dam at *C*, and a 4-in. discharge which is carried to the reservoir. To supply the needs of the town it must be kept in operation about 16 hours per day.

Only Pump During Off-Peak Hours of Night

The pumping of mine water is done during the off-peak hours of the night. At the present time from 300,000 to 400,000 gallons of water accumulates in the big sump each day. This quantity can be pumped by one of the two units in a single shift. The two centrifugal pumps are put in operation on alternate nights. Consequently the sump capacity is three times that of the daily accumulation of water, which in turn is one-half the 8-hour capacity of the two centrifugal pumps. Thus ample provision has been made for any increase in the quantity of water that may have to be pumped at any time.

Auxiliary tap lines have been provided whereby the 4-in. discharge column from the triplex pump or the 12-in. discharge column from the centrifugal pumps may be drained back to the big sump. Through the same drain line by a manipulation of valves the centrifugal pumps may be primed from the triplex pump.

A 4-in. drain line connects the 12-in. discharge of the centrifugal pumps with the big sump. A 2-in. line connects this drain line with the discharge of the triplex pump as shown in Fig. 2. Thus by opening the proper valves either water column in the airshaft may be drained.

As before mentioned, the water head on the triplex pump is 403 ft., and against this the pump cannot start. By opening a check valve *B* on the 2-in. line it is enabled to pick up water against practically no head. Then a gate valve at *A* is opened, after which the check valve is closed, thus allowing the triplex pump to take up its load gradually against the large head.

Safeguarding the High-Voltage Lines

Alternating current at a potential of 2,300 volts is conducted from the substation on the surface to the underground pumproom by a No. 1 3-conductor lead-armored cable which is strung down the No. 1 shaft in fresh air, and leads to the rear of the switchboard. The incoming line at 2,300 volts passes through disconnecting switches and oil switches for starting and thence leads to the motors. Direct connections are made from the oil switches behind the main panel to the motors by wires carried in conduits under the floor.

By bringing the control panel flush with the sidewall of the pumproom, locating all control apparatus in an offset, keeping the high voltage behind the starting panel and under the floor in conduits, the dangers involved in handling heavy voltages in close quarters are eliminated. The starting panel is equipped with three hand-operated starters and three voltmeters which latter are tied in with the high-voltage equipment by a current stepped down to 110 volts. These features are to be recommended for all underground pumprooms where alternating current is used.

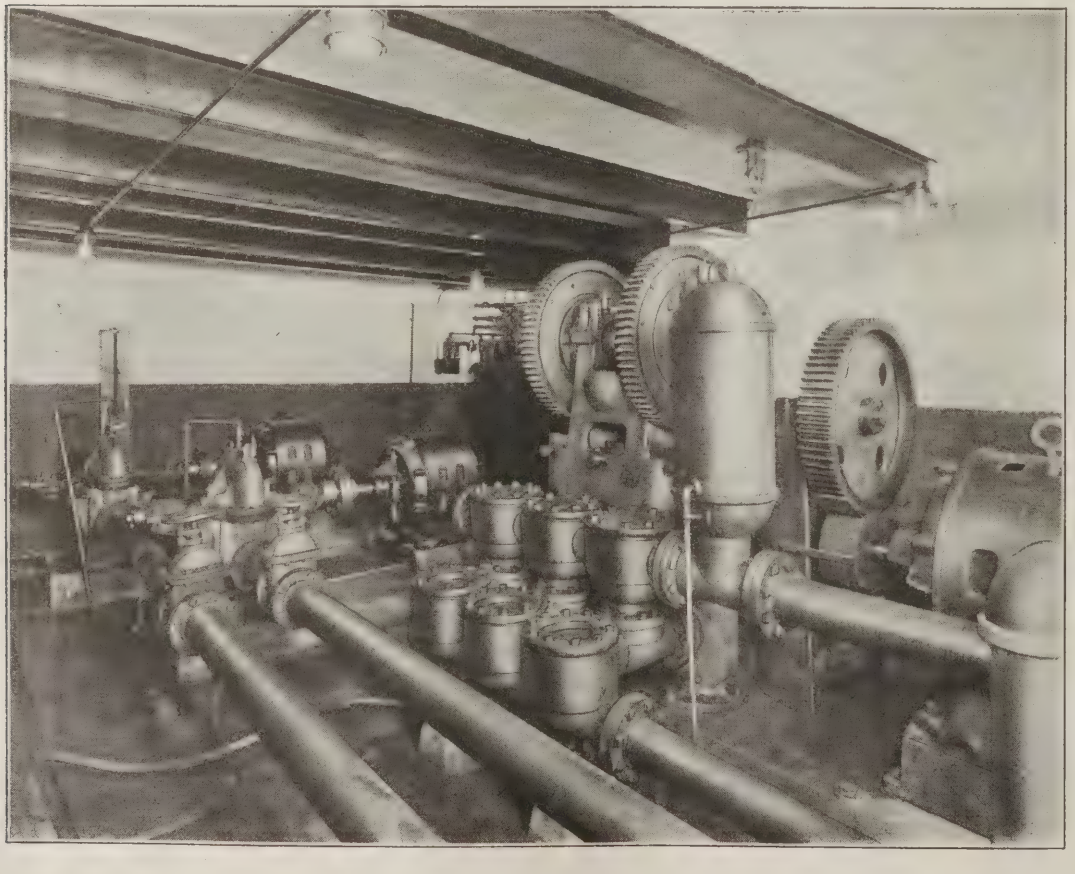

FIG. 4

Pumproom, Isabella Mine

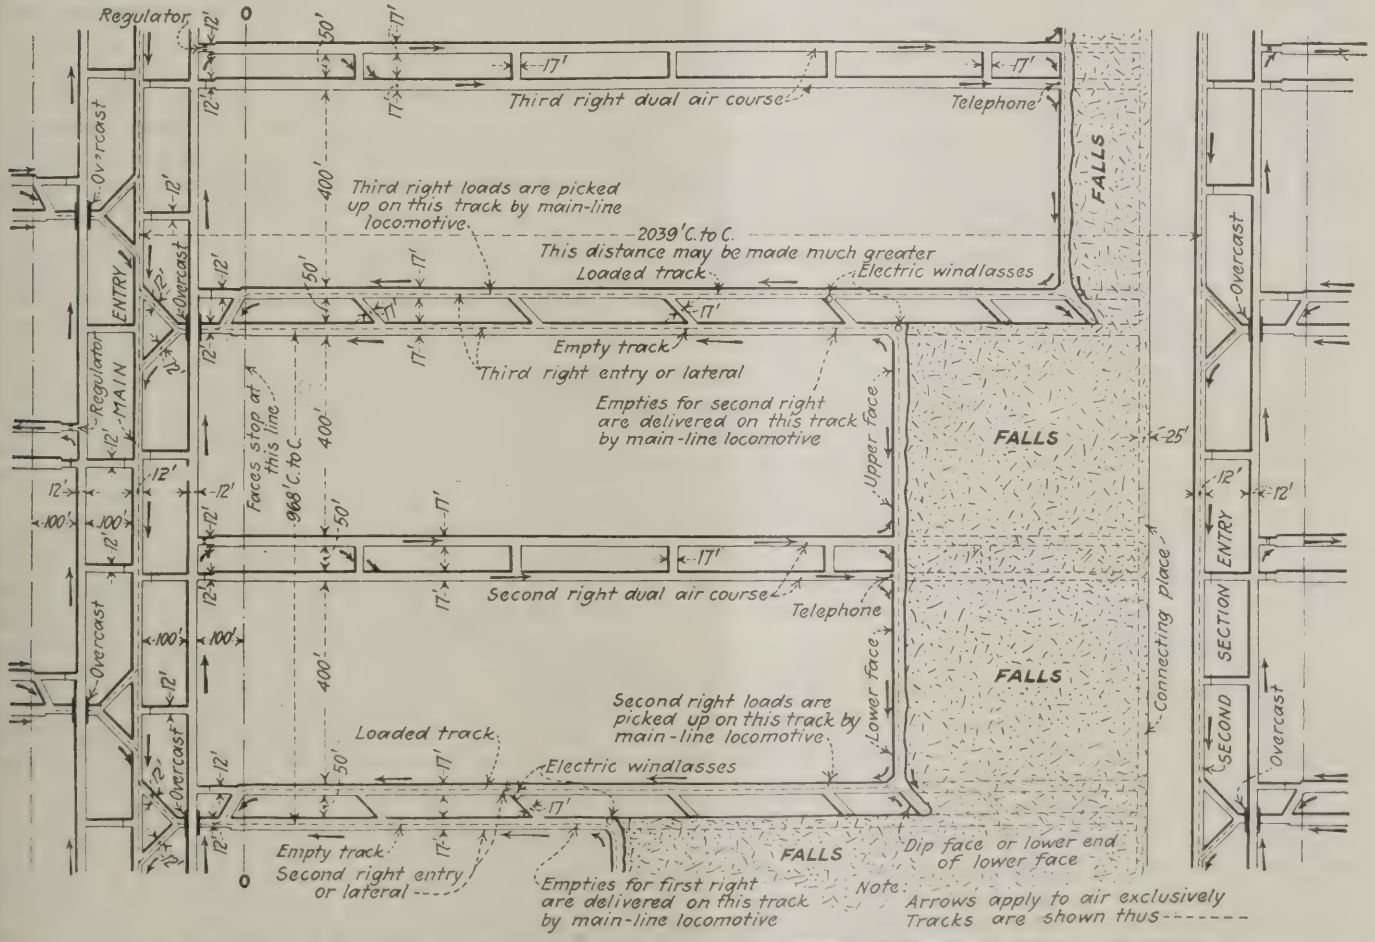
Mine water is pumped by one of the two 750-gal. single stage centrifugal pumps driven by 60-hp. squirrel-cage motors which can be seen in the rear and on the left. The large pump on the right is a 150-gal. plunger type triplex pump for pumping fresh water. This is driven by a 50-hp. squirrel-cage motor, the lift being 403 ft. as against 138 ft. which is the lift of the other pumps. The starter panel can be seen to the left and behind the triplex pumps.

Gathering Without Animals, Locomotives or Conveyors

Longwall Retreating by Panels with Cars Placed Continuously Before Face by Portable Electric Hoists and Assembled in the Same Manner When Loaded—Every Locomotive Hauls Full Trips Exclusively

By F. C. Cornet*
New York City

THE mining method shown in the illustration accompanying this article and explained hereinafter applies to seams of such thickness that cars can be loaded at the working face without excavation in either the top or the floor.



The main-entry system shown to the left of the illustration, which consists of a haulageway flanked on either side by a so-called main aircourse, is driven on the full pitch of the coal, which, it is assumed, does not exceed 4 per cent. At intervals of nearly 1,000 ft. center to center, lateral headings (hereinafter called "laterals" for brevity's sake) are driven two abreast at right angles with the main entry, that is, on the strike of the seam. For brevity also the lower member of a lateral will hereafter be called the "empty track" and the upper member will be designated as the "loaded track."

Halfway between two successive laterals a so-called "dual aircourse" is driven parallel with the laterals. Between any dual aircourse and the nearest lateral, above and below, a solid 400-ft. pillar is left to be mined retreating after at least two successive laterals and the intervening dual aircourse have been driven to their assigned limit.

The fact that these solid 400-ft. pillars constitute for the laterals and the dual aircourse an effective protection that will last as long as these places are used makes it permissible to drive them of such a width that they can be extended without payment for yardage. I have assumed that a width of 17 ft., as shown on the drawing, would put these places out of the yardage-paying class, leaving in the narrow class, subject to yardage, only the main-entries and the short necks by which the main haulageway and the aircourses are connected with the laterals and dual aircourses respectively.

When two successive laterals and the intervening

*Consulting engineer.

METHOD OF MINING ELIMINATING USE OF LOCOMOTIVE EXCEPT FOR FULL-CAR TRIPS

The locomotives in the scheme planned keep continuously traveling, loaded always to their capacity except when driving what the author calls the laterals and the air courses. The air currents cannot leak from intake to return, as a 400-ft. pillar unbroken by crosscuts separates them during the real operating stages. The cars, drawn to the highest point of the face by an electric windlass, can be lowered to any point at the face desired. Electric windlasses assemble the cars and the locomotives pull them out. The cutters have straight cutting without traveling from face to face. Absolutely nothing spoils this picture except the requirement of an even, favorable grade, which in many places can be conceded, and the need for a suitable roof or height of cover. As hand loading is provided the area to be supported back of the face is a minimum.

dual aircourse have reached the limit assigned to them, their ends are connected up, as shown, by a wide place simultaneously driven from the dual aircourse toward both laterals and from each of the latter toward the dual aircourse. The outby rib of this connecting place forms a longwall face intended to be driven toward the main entry until it reaches the line *OO* drawn parallel with the main entry sufficiently far from the near main aircourse to protect the latter by an adequate barrier pillar that will not be mined until the time when the main-entry pillars are themselves drawn.

A look at the drawing shows that when a newly formed longwall face starts driving, it is perfectly straight from end to end, including that lowermost part of it marked "dip face" on the drawing. As the longwall face drives on, however, the direction of the dip face is gradually changed to a slant, as shown. The reason for this will appear below.

As to the main part of the face, it will be maintained straight on the full rise of the seam, as shown. This part of the face I have divided arbitrarily into two sections, marked "upper face" and "lower face" on the drawing, the supposed dividing line between the two being opposite the lower member of the dual aircourse, near the telephone. The reason for my making this imaginary division will appear later.

No Bonding Needed Along Longwall Face

The illustration plainly shows in broken lines the great simplicity of the whole track system. If trolley locomotives are used, all the tracks will be bonded and equipped with trolley wires, except along the longwall faces. As will appear later, no gathering locomotives and no animals will be used.

The main-line locomotive, coming up the main heading with a full trip of empties, keeps on its way past the lateral for which it is bound, until the last car of the trip has cleared the point of the upper switch giving access to the lateral. The whole trip is then dropped into the empty track of that roadway, which, as may be seen, is straight. The empties thus dropped are intended for the longwall face below the empty track.

When dropping a trip of empties into a lateral, advantage is taken of the momentum gained by the cars while running downhill on the main entry. This will make it unnecessary for the locomotive to begin pushing the trip until such time as every car is on the straight track and beyond the overcast. On this long track tangent the cars, even if pushed, will not be likely to leave the rails unless the former are in bad condition and the track is shaky.

Provision for Turning the Locomotive

The locomotive, having placed the empties on the straight track as far as required, will run back the way it came to the main heading, to re-enter the lateral immediately by way of the lower switch leading to the same lateral. This maneuver is necessary in order to have the locomotive, when going out, turned the same way as when coming in. If storage-battery locomotives are used, it will not be necessary to run the locomotive around in the manner described. After re-entering the lateral, the locomotive will switch to the loaded track, where a full trip of loads is standing already made up, waiting to be hauled away. These are the cars that have been loaded at the longwall face above the loaded track.

At some convenient point along each empty track an electric windlass is placed, the steel rope from which reaches outward as far as the outby end of the trips of empties delivered by the locomotive. Although I have shown this windlass placed where the empty car curves toward the face, another location along the empty track might equally well answer the purpose, which is to move the empties from the point where the locomotive has left them to a point at or near the head of the longwall face where they can be allowed to run by gravity down the loading track along the face until stopped by their brakes at the point where they are needed. The cars thus will be brought to loading positions, not one or two at a time but in groups of fifteen or twenty-five, or even more units, as the face foreman may think best. The grade being in favor of the movement of the cars it is easy to spot them at any point desired.

At some appropriate point along each loaded track, not necessarily where shown on the drawing, is also placed an electric windlass, the steel rope of which reaches as far inward as the foot of the dip face. It is by means of this windlass and rope that the cars, dropped by gravity from the main face after loading, as well as the loads drawn away from the dip face, will be made into full trips all coupled up, ready to be hauled away by the locomotive, as previously explained.. Although windlasses answering perfectly the comparatively limited requirements of these operations are machines that may be rapidly and inexpensively moved from one location to another, it will be best so to place them that they will have to be moved only at long intervals, say 200 or 300 ft. at a time.

Locomotive Invariably Handles A Full Trip

The grades, where grades there are, being in favor of the loads, the number of empties that the locomotives can conservatively haul up the controlling grade will determine the number of cars constituting what I have repeatedly designated above as a full trip. Fifteen-ton locomotives will haul with comparative ease forty-five ordinary empty 2-ton cars up a 4-per cent incline, which is the maximum grade assumed at the beginning of this article. The face lengths and other measurements appearing on the drawing permit the placing of forty-five empties and the formation of trains of forty-five loads in the laterals at all stages of the operations down to the time when the longwall faces get to the line *OO* when the laterals, being worked out, are abandoned.

All conditions required to minimize the cost of main haulage are met by this system: First, single destination on every trip made; second, full trains hauled at all times; third, no shifting to be done by the motors in the laterals; fourth, no reduction in the length of trains at any stage of the operations, no matter how nearly the territory saved may be worked out. The gathering is done at much lower cost by the combined windlass and gravity method than it could be by animals or gathering locomotives under the most favorable circumstances.

In ordinary mine layouts, the lateral headings generally are short, seldom exceeding 1,500 ft., due to the fact that gathering by either locomotives or animals rapidly becomes too expensive when the laterals are made longer. This drawback is entirely eliminated when the work is done in the manner just explained. The cost of gathering remains at the same low figure no matter how long the laterals may be. Longer laterals mean less section headings of the kind shown at the right of the drawing. They also mean less trackage and fewer

overcasts, as well as more efficient supervision and increased safety.

I realize that some engineers will object to long laterals, on the ground that, in the system I am describing, intensive, paying production is delayed until two consecutive laterals have been driven to their limit and connected up at their ends. Of course, the execution of such preliminary work will absorb more time than certain operators can, or are willing to, afford before getting tangible returns from the money spent in development work.

I freely admit that this new mining method is designed only for those operators who have at their disposal capital that will permit them to wait reasonably long for returns, provided that by so doing the dividends earned will be larger than they could possibly be through any other method. The large coal area tributary to a lateral is in itself a factor that will amply repay the operator for the time spent in driving these long roadways.

Assuming the layout to accord with the figures appearing in the illustration, ninety men could, without interfering with one another, work together along the 900-ft. face. When pressed for coal, 120 men could work there without appreciable decrease of individual output. Supposing, as already seen above, the imaginary dividing line between the upper and lower faces to be at the lower member of the dual air course, as many men could work above as below said imaginary dividing line—that is, sixty on each side of it. The mining law of West Virginia, which I had in mind when designing this method, limits to sixty the number of men who may be employed on a single split of air, no matter how far apart consecutive laterals may be. That is why the aircourse is placed between the laterals. By placing it exactly halfway between the two, the permissible maximum number of miners may be employed on either side without crowding them more on one side than on the other.

Ventilation Simply Arranged and Effective

The ventilation system requires only one regulator. It makes no difference in which member the regulator is built, provided the other member is blinded, as shown, by a stopping in order to confine regulation to one point only. This stopping is the only one necessary in connection with the dual aircourse, both members of which, combined, offer an easy passage for the air. None of this ventilating current can possibly be lost, as it has no way to reach the returns except through the workings to be ventilated. In no other system is all waste of air thus made impossible in working headings.

Another objection that may be raised against long laterals is that the maintenance of such arteries grows more expensive as they get older. Of course, the longer a lateral, the longer it will have to be kept in service and maintained in more or less perfect condition. The above objection is justified in ordinary practice where the driving of contiguous rooms to one side (and sometimes to both sides) of the lateral generally so weakens the overlying strata that maintenance of said lateral becomes expensive. This, however, is not likely to happen where the overlying strata remain supported to the last by solid 400-ft. pillars, as is the case with the layout represented by the drawing.

Let us assume that the seam worked has an average thickness of 54 in. of merchantable coal and ninety loaders are employed. which would allow each man 10 lin.ft. of face. A cut 10 ft. deep will throw 16 gross tons of coal per 10-ft. section. This is just what the average loading capacity would be among so many men working together shoveling coal into 2-ton cars standing 32 in. high above the rail.

We have seen that the locomotives would deliver the empties near the top of the workings in 45-car trips. The forty-five cars, dropped together or in two or three sections rapidly following each other, would allow every two loaders one car from each trip. Each pair of men would require sixteen cars and the ninety men 720 cars daily, which makes it necessary for the locomotives to make sixteen trips to and from each lateral in the course of an 8-hour shift. Assuming there are twice as many cars, empty and loaded, on the roads going and coming, or standing at the tipple and on storage tracks as there are at the different faces, every car in actual service will make 5.33 trips every working day, a performance unheard of in room-and-pillar mines, but just fairly satisfactory in well-planned longwall mines where the tracks are good, the ventilation abundant and the locomotives not lacking.

Chain machines of the ordinary room-and-pillar type, cutting 10 ft. deep, could be applied easily to such work as I am describing. With the difference that there is no sumping to be done, these machines would work just as they do in rooms, cutting across a 900-ft. face instead of one of 25 or 35 ft. Using two cutters simultaneously, both traveling downhill, for example, the upper machine starting at the empty track, the lower one at the lower member of the dual aircourse, the cutters could be depended upon to travel at the rate of a foot a minute, taking into account the time necessary to change all the bits of each machine twice. Thus the cutting of the whole face would be done easily in the course of an 8-hour shift or, to be exact, in 7½ hr. This performance of 450 lin.ft. a day, while not extraordinary in longwall practice, is 100 per cent better than in room-and-pillar work, where a chain machine is considered to be doing very well if it cuts ten 22-ft. places daily.

The chain cutter, perhaps the most remarkable instrument of production that the mechanical genius of this country has put at the disposal of coal operators, also is the one to which our mining methods have been slowest in adapting themselves.

What I said in my article in *Coal Age* of Jan. 25, 1923, concerning timbering and conveyor shifting applies in a general way to the method described above, the only exception being that in this case there is a track to be shifted instead of a conveyor. One job is about the same as the other.

Wagon Mine Operated by ¾-Yard Shovel Is an Alabama Innovation

ONLY a quarter mile from the Pocahontas station of the St. Louis & San Francisco R.R., the Pocahontas Coal & Mining Co., of Carbon Hill, Walker County, Ala., is nevertheless temporarily running a stripping as a wagon mine. Excavation just now is being made in the shallower stripping, which averages about 14 ft., and the work is done by a Bucyrus extra-high-lift shovel with a ¾-yd. dipper, a 22-ft. 6-in. boom and a 17-ft. dipper handle, the shovel being mounted on caterpillars. The coal is 28 in. thick and is covered by a 4-ft. bed of blue slate which can be removed without blasting. The shovel makes a 25-ft. cut, casting the overburden over into the previous excavation. The stripping is all done at night, and the shovel during the day loads coal into wagons along the bank.

Storing and Reclaiming Coal by Portable Conveyors Under Difficult Conditions

By D. A. Thomas*
Birmingham, Ala.

A LONG-TERM contract for convict labor made it necessary for the Montevallo Mining Co. to keep on mining coal when there was practically no demand for it. This made it necessary to store about 10,000 tons of small-size coal, and it was soon apparent that this coal could not be handled without machinery. Consequently three portable belt conveyors manufactured by the Barber-Greene Co., of Aurora, Ill., were installed in September, 1921, one being 60 ft. long and the other two 30 ft. Two were equipped with 5-hp. motors and one with a motor of 3 hp. All the belts were 16 in. wide.

Before the conveyors were installed some of the coal was unloaded from the cars to piles by shovels. After the conveyors were installed a section was cut underneath the track and a sheet-steel hopper built. Two men push the coal from the cars into the hopper, from which it is carried by the conveyors to the storage pile, which sometimes reaches a height of 27 ft. At times all three conveyors are used in series, sometimes only one and sometimes two. When piles 27 ft. high are made the 60-ft. conveyor is used on the far end of the line of three conveyors. With all three in series 50 tons of coal could be handled per hour, using seven men, but our average speed for all work was near 25 tons per hour. Approximately 150 tons could be unloaded per day and about 300 tons could be loaded back into the cars.

In less than four months 5,000 tons was loaded and 4,500 unloaded. The work was rendered particularly difficult by the contour of the ground, the railroad being 15 ft. above the storage yard. With three conveyors in series it was possible to pile the coal so far from the track that a large quantity of it could be stored and to do it in piles containing three different sizes: domestic nut, chestnut and slack. The work is, of course, irregular.

Three Conveyors Shift Coal Around Corners

In figuring operating costs the three conveyors are considered as a unit, because their chief use is in series. It is estimated that they are good for at least ten years of life and that repairs and maintenance should not exceed $120 a year. The labor for loading 5,000 tons is figured at 8c. a ton and for unloading 4,500 tons at 5c. a ton. The total operating cost for the four months is $858.80, or 9.04c. per ton.

If this work had been done by hand it would have cost at least 25c. a ton on account of the difficulties arising from the unfavorable contour of the ground. This would make a total cost of $2,375; so the machines saved $1,516.20 in four months. This, which is at the rate of $4,528.60 a year, is equivalent to a return of 152 per cent on the investment. The saving per ton is 15.96c. A summary of these costs is given in the table herewith.

A further saving is effected because there is less breakage of the domestic-nut size when handled by the conveyors than when shoveled by hand. About

*Formerly vice-president, Montevallo Mining Co.

Loading Out Coal

In foreground 60-ft. portable conveyor which is fed by a 30-ft. conveyor which is itself fed by another 30-ft. conveyor passing under the trestle. Note also in the foreground the handy method of suspension and transportation of the conveyor.

As Seen from Another Angle

The slats on the conveyor belt by which the railroad car is being loaded are plainly visible. Few conditions for a storage yard are as unfavorable as at this mine, the coal having to be lifted from the ground to the top of a car that is perched on a 15-ft. trestle.

3,500 tons of this size was stored in the four months, and I should estimate that the reduction in breakage was 3 per cent, or 105 tons. Breakage reduces the value of the coal from $3.50 a ton to $2, which is equivalent to a saving of $157.40 in the four months, or $500 a year. This would make the approximate saving in the operation of the plant over hand labor about $5,000.

COST OF OPERATION OF THREE PORTABLE CONVEYORS AT MONTEVALLO MINES

Depreciation on $3,000; estimated life 10 years	$300.00
Average interest @ 6 per cent— $11/10 \times \frac{\$3,000}{2} \times .06$	99.00
Repairs and maintenance	120.00
Total annual fixed charges	$519.00
Fixed charges prorated for four months	$173.00
Power—3,040 kw.-hr. @ 2c. per kw.-hr.	60.80
Labor loading, 5,000 tons @ 8c. per ton	400.00
Labor unloading, 4,500 tons @ 5c. per ton	225.00
Total operating cost for four months	$858.80

Total tonnage handled (5,000 + 4,500) = 9,500.
Cost per ton, $858.80 ÷ 9,500 = 9.04c.

How to Calculate Washed Coal and Refuse From Ash and Sulphur Determinations

By Kenneth D. Dodds*
Pittsburgh, Pa.

In order to know the extent to which a coal washery is separating raw coal into washed coal and refuse, the proportion of each product in relation to the original material must be determined. If each lot of raw coal, washed coal and refuse were weighed, the percentage of the mine production delivered by the washery as cleaned coal and as refuse could be ascertained by means of a simple calculation, using the weights involved; that is,

$$\text{Percentage of washed coal} = \frac{\text{Weight of washed coal}}{\text{Weight of raw coal}} \times 100,$$

$$\text{and Percentage of refuse} = \frac{\text{Weight of refuse}}{\text{Weight of raw coal}} \times 100.$$

The accuracy of the results obtained by such a method would be limited only by the accuracy of the scales on which the weighings were made and the carefulness of the operator, but the method would nevertheless be impractical because of the labor involved and the necessity of running the washery intermittently.

A simpler procedure, involving elementary analytical chemistry and mathematics, while avoiding the inherent difficulties of direct weighing, nevertheless yields satisfactory results. The principle of this method may be stated in this manner: The magnitude of any property of a mixture of substances is equal to the sum of the values of the same property in each constituent multiplied by the percentage of each constituent in the mixture. This axiom is the so-called "Law of Mixtures." In mathematical terms,

$$Z = Az + Bz + Cz + \ldots\ldots\ldots\ldots N_z;$$

where Z is the value of some property (specific gravity, ash, sulphur, etc.) of the mixture, z is the value of the same property in each of the components which are present in the percentages A, B, C, etc.

If raw coal is regarded as a mixture of washed coal and refuse, the application of the above general equation is readily understood. To illustrate by an actual case, let us consider a coal and its products which on being analyzed for sulphur and ash gave results as shown in Table I.

*Instructor in metallurgy, School of Mines, University of Pittsburgh.

TABLE I—ASH AND SULPHUR IN COAL AND WASHED PRODUCTS†

	Per Cent Ash	Per Cent Sulphur
Raw coal	16.9	2.59
Washed coal	6.1	0.90
Refuse	55.9	8.48

† Fraser & Yancey, Transactions American Institute of Mining and Metallurgical Engineers; preprint with Mining and Metallurgy.

If X represents the percentage of washed coal, then $1 = X$ will, of course, be refuse. Substituting the percentages of ash from Table I in the formula, we get

$$16.9 = 6.1X + 55.9(1 - X)$$

from which $49.8X = 39.0$

and $X = 78.3$ per cent (washed coal)

$1 - X = 100 - 78.3$

$= 21.7$ per cent (refuse)

Thus if a few simple analyses are made, valuable information can be obtained easily and quickly.

One might reasonably expect, on first thought, that the result obtained by using sulphur percentages would be the same as that from ash. For some coals this is true or nearly true, but for others, as will be shown later, there is a considerable difference between the two. With the coal already discussed the calculation on the basis of sulphur is

$$2.59 = 0.90X + 8.48(1 - X)$$

$$7.58X = 5.89$$

$X = 77.7$ per cent (washed coal)

$1 - X = 22.3$ per cent (refuse)

For this coal, then, either ash or sulphur may be used as the basis for the computation, with a fair agreement in the final figures. This does not hold true, however, for all coals. As an example of one which does not give the same result in the two instances, consider the data in Table II.

TABLE II—ASH AND SULPHUR IN ANOTHER COAL AND WASHED PRODUCT‡

	Per Cent Ash	Per Cent Sulphur
Raw coal	17.62	3.54
Washed coal	6.65	2.44
Refuse	53.15	9.09

‡ H. C. Ray, *Coal Industry*, December, 1919.

When the figures for ash are taken, we find

$$17.62 = 6.65X + 53.15(1 - X)$$

$X = 76.4$ per cent (washed coal)

$1 - X = 23.6$ per cent (refuse)

Similarly for sulphur,

$$3.54 = 2.44X + 9.09(1 - X)$$

$X = 83.5$ per cent (washed coal)

$1 - X = 16.5$ per cent (refuse)

The difference between these two values is, of course, much too great to be considered as even an approximate check, and the question, therefore, arises as to which of the two values correctly represents the conditions. When we recall that ash and sulphur are not present in the materials as one single compound but are independent of each other we suspect that any removal of one does not necessarily involve the elimination of a corresponding quantity of the other. Consequently, if it can be demonstrated that these two impurities are not interdependent, it will follow that both of the foregoing results are true—83.5 per cent if only sulphur is taken into account and 76.4 per cent when ash alone is considered. If ash and sulphur are not equally removed, then the ratio of each of these to the total impurities (i.e., the sum of ash and sulphur) will be different for the raw coal, washed coal and refuse, while if the contrary condition obtains, these ratios will be the same in each case. The ratio of ash to total impurities

in the raw coal is $\frac{17.62}{17.62 + 3.54}$ or 83.3 per cent, and likewise for the two products as in Table III.

TABLE III—RATIO ASH AND SULPHUR TO TOTAL IMPURITIES IN COAL AND WASHED PRODUCT

	Ash Total Impurities Per Cent	Sulphur Total Impurities Per Cent
Raw coal	83.3	16.7
Washed coal	73.2	26.8
Refuse	85.4	14.6

These figures show at once that the washing process does not eliminate ash and sulphur in the same proportion, but that instead sulphur is concentrated in the washed coal and ash in the refuse. This segregation of impurities accounts for the difference in percentages of washed coal observed when calculations are based on each impurity. If instead of segregating, sulphur and ash left the raw coal in equal proportions, ratios such as those in Table III would be identical for raw coal, washed coal and refuse. This means that the relative quantities of each impurity would be the same for the three materials, and would differ only in amount. Hence in this case 83.3 per cent of the total impurities in both the washed coal and the refuse would be ash, the same as in the raw coal. If this state of affairs existed, the analyses would be as shown in Table IV.

TABLE IV—ASSUMING PERCENTAGE OF ANY IMPURITY TO TOTAL IMPURITY IS SAME IN WASHED COAL AND REFUSE AS IN RAW COAL

	Per Cent Ash	Per Cent Sulphur
Raw coal	17.62	3.54
Washed coal ([6.65 + 2.44] x 0.833) ([6.65 + 2.44] x 0.167)	7.57	1.52
Refuse ([53.15 + 9.09] x 0.833) ([53.15 + 9.09] x 0.167)	51.85	10.40

On substituting the above derived percentages in the formula, it is found that the same result is obtained on each basis:

Based on ash: $17.62 = 7.57\,X + 51.85\,(1 - X)$
$X = 77.3$ per cent

Based on sulphur: $3.54 = 1.52\,X + 10.40\,(1 - X)$
$X = 77.3$ per cent

The examples cited show that washery calculations cannot safely be based on ash or sulphur indiscriminately, unless it is known that these are eliminated in the same, or substantially the same, ratio.

All coals on being washed behave in one of three ways: sulphur and ash are either removed in the same ratio, in widely different ratios, or as an average between these extremes. The importance of knowing upon which impurity to base calculations is, therefore, self-evident. A little study will convince one that if total impurities are considered in preference to any single impurity, any differences in ratios of elimination will be automatically adjusted, and regardless to which of the three above classes the coal may belong, the percentage of washed coal as indicated on this basis will be the same as if sulphur and ash were indeed eliminated equally. This is proved by adding the analyses shown in Table II and rearranging as in Table V:

TABLE V—TOTAL IMPURITIES IN RAW COAL, WASHED COAL AND REFUSE

	Per Cent Ash + Sulphur
Raw coal	21.16
Washed coal	9.09
Refuse	62.24

Substitution of these figures in the formula gives the following equation,

$$0.2116 = 0.0909\,X + 0.6224\,(1 - X)$$
$X = 77.3$ per cent (washed coal)

This result, unlike those obtained by calculating on sulphur and ash separately, is correct for both.

As the purpose of washing coal is to remove both undesirable substances to as great an extent as possible, it seems that total impurities should be adopted as the fundamental basis of washery calculations, rather than any single impurity.

NOTE—The author is indebted to Dean H. B. Meller and Prof. E. G. Hill, of the University of Pittsburgh School of Mines, for helpful suggestions in the preparation of this article.

An Anthracite Mine Car Discovered Dating Back, at Least, to the Year 1845

NOT often do mining relics of the past come down to us in such an excellent state of preservation as the mine car that was found in the old workings of the Hillman Bed at the No. 14 Colliery of the Pennsylvania Coal Co., between Pittston and Wilkes-Barre.

This mine car was found in some old workings that had been opened by a tunnel. From the records in the possession of the Pennsylvania Coal Co. it was found that no work had been done in this section of the mine since 1845. So there is no doubt that the mine car dates back at least to that year. It is therefore more

A MANIFEST PROGENITOR OF TODAY'S HARD-COAL CAR

Even today the anthracite car usually is a box on a track without any flare over the top of the wheels. The narrowness of the roadways prohibits the use of the wide cars of the bituminous-coal regions. In the soft-coal districts one is led to wonder which is the more remarkable, the width of the gage or the side overhang of the car body.

than 78 years old—how much older is problematical.

The Hillman Bed, in which it was used, is 8 ft. thick. The car contains 18.5 cu.ft. level full and with a 6-in. topping it would contain 6.5 cu.ft. more, or a total capacity of 25 cu.ft. It is 2 ft. 2 in. wide at the top and 1 ft. 8 in. wide at the bottom. It is 6 ft. 1 in. long and the height of the inside of the car is 1 ft. 7 in. The wheels are of a diameter of 16 in. and the gage is 24 in.

When the car was found the running gear, bottom sills and two of the uprights of the body were practically intact. From these uprights the rest of the body was built.

MECHANISM OF BOILER-SCALE FORMATION.—At the Pittsburgh experiment station of the U. S. Bureau of Mines the mechanism of scale formation in steam boilers is being studied, including the effect of temperature, pressure, character of surfaces and concentration of the water. A continuous test is being conducted on a commercial boiler in actual operation, in which a part of the suspended matter is continuously removed by an external filter through which the boiler water is circulated. The influence of added constituents is being noted.

Setting Diamonds in Drill Bits*

By George J. Young†
San Francisco, Calif.

SETTING a diamond in a diamond bit is somewhat similar in principle to setting a filling in a tooth, and the diamond setter develops a skill which is comparable to that shown by a good dentist. Seldom have the tools of the diamond setter been described, and this probably is because each diamond setter has his own kit. The work of diamond setting is a necessary accessory to diamond drilling and usually is done on the job. On the thoroughness of the setting depends not only the success of the drilling but also economical use of diamonds and reasonable costs.

A good diamond setter should have excellent mechanical training and familiarity with the tools of the craft as well as a good eye and innate aptitude for the task. Diamond setting is a fussy job, but it cannot be done in a fussy manner. To begin with a good light is necessary. Next, a solid bench about 6 ft. long with a low edge board to prevent tools from rolling off is essential. It should be equipped also with a good vise. The top of the table should be smooth and free from cracks.

The only other fixture necessary is a vertical stand which can be extemporized from pipe, pipe fittings, and a floor flange as shown in Fig. 1. This stand is used to support a breast drill, and downward pressure can be obtained by pulling down upon the end of the horizontal rod.

To hold the bit rigidly in position in the vise, a bit holder made as shown in Fig. 4 is used. The bit screws into the upper end as shown. It can be placed horizontally or vertically, as required. The necessary tools fall into several classes—measuring, cutting and drilling, calking, swaging, and miscellaneous.

*From *Engineering and Mining Journal-Press.*
†Associate editor, *Engineering and Mining Journal-Press.*

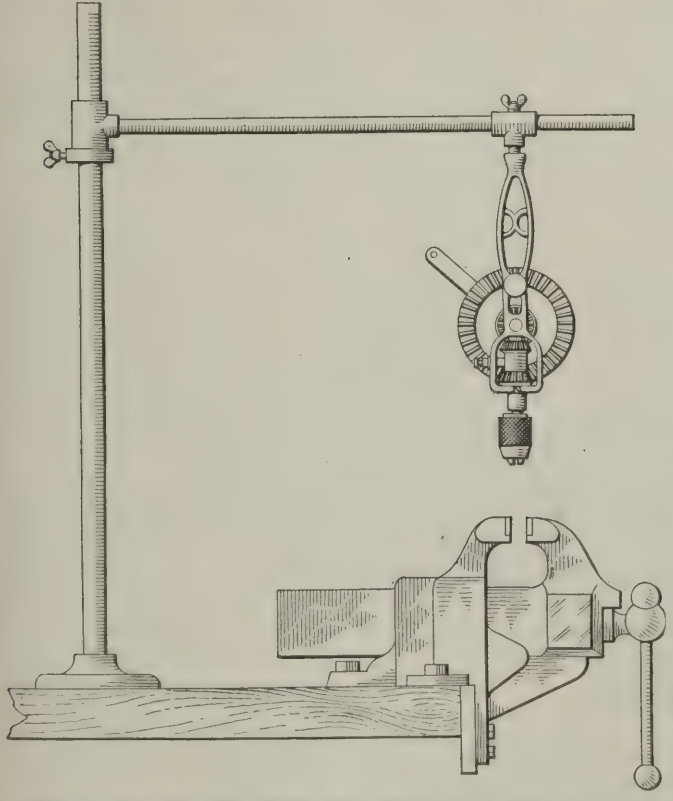


FIG. 1—STAND AND VISE FOR DRILLING BIT HOLDER

A simple pipe stand is used to support the hand drill. This is adjustable in two directions. Pressure on the horizontal pipe holds the drill to its work.

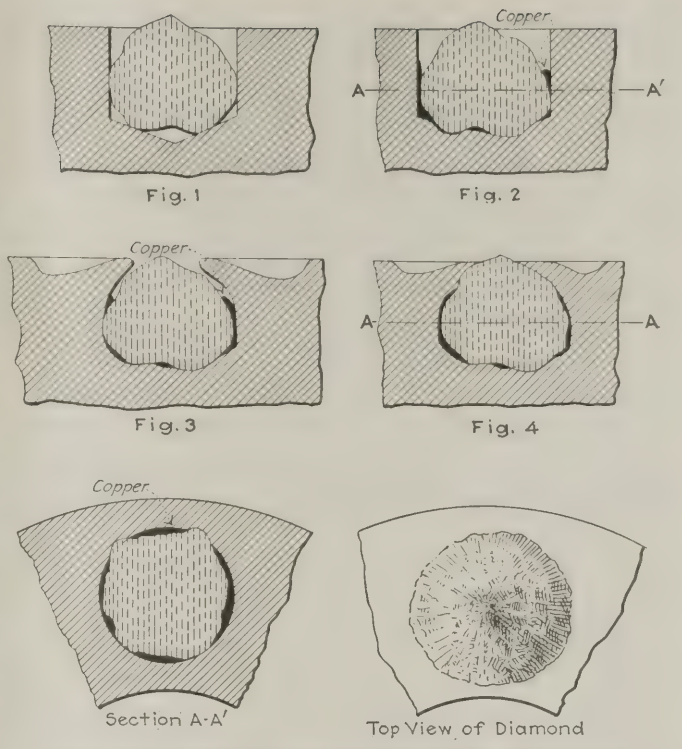

FIG. 2—SUCCESSIVE STEPS IN SETTING DIAMONDS

The hole is drilled of an accurate depth and width so that the diamond will project 1/100 in. and so that the hole will be well suited after chiseling to receive the diamond. The diameter is then set in as in Fig. 1. Copper strips are cut with a chisel and wedged in around the diamond as shown in Fig. 2, holding the sides and giving bearing to the bottom. Then the steel of the bit is swaged all around from a sufficient distance back from the diamond so that the diamond is buried in the bit without bringing sufficient pressure on that precious piece of abrasive to cause it to split. See Figs. 3 and 4.

The tool kit comprises the following: For measuring, two pairs of inside and outside calipers and a caliper square with inside-outside jaws; for cutting, a diamond point, a cape chisel, and small cold chisels of various sizes; for drilling, twist drills from $\frac{3}{16}$ and $\frac{1}{4}$ in. diminishing by $\frac{1}{32}$ in. successive sizes and both wire gage and regular sizes; off-set, round-nose, and square and round-end calking tools; swages, center punches, and sets; miscellaneous, three sizes of ball-pein hammers, 4, 8, 12 oz.; a "pick," copper set, snips, 10-in. Stillson wrench, pincettes, gage rings, magnifying glass, and portable balance with carat weights.

Stone Is Carefully Bedded in the Steel

The tools used in setting the stones are shown in Fig. 4. In setting a diamond the bit is marked by means of a center punch at the positions of the principal stones. The stones are carefully selected, larger stones for the important cutting positions and smaller stones, used stones, or fragments for the clearance positions. It is worthy of note that the diamonds as purchased are chosen from a stock first selected by the dealer.

Having selected a stone, it is carefully studied and decision made as to the cutting position to which it is best adapted. Its maximum diameter is measured, as well as its maximum height. The cutting surface of the stone is so placed that it will be $\frac{1}{100}$ in. above the bit. The proper diameter of bit is then selected and a hole of the right depth bored. By means of the chisels the hole is trimmed and cut to take the diamond. Copper strips are cut with the cold chisel and wedged in around the diamond until it is securely held at all points.

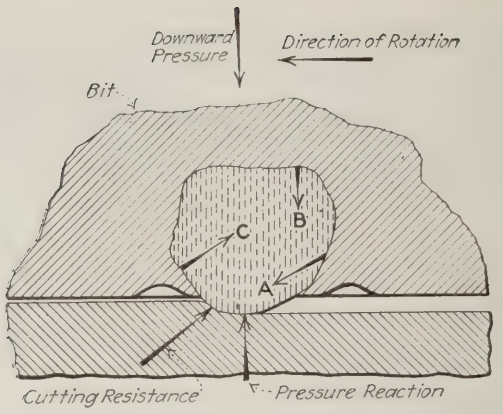

FIG. 3—FORCES ACTING ON DIAMOND WHEN CUTTING

This figure shows the couples acting on the diamond both to displace it and to keep it in position. If the diamond does not get the right kind of support it is likely to turn and work loose. The recovery will be quite difficult and in cases it may be lost entirely.

These bits of copper seat the diamond on the bottom and sides.

The steel of the bit is then swaged all around from a sufficient distance back to afford enough metal to close in about the diamond. The "collar" of metal thus drawn around the upper part of the diamond is gradually swaged closer and closer, avoiding any pressure upon the diamond. It is finally drawn down upon the diamond, the setter closing it in from the bottom up until the diamond is almost completely buried in the steel.

The last operation consists of calking the fringe of metal about the stone until it bears evenly upon it at all points and leaves only the upper surface of the stone exposed. This operation is a delicate one, for the setter must hit just hard enough to draw the metal without allowing the stone to get any more than a light effect from the blow. There is danger of splitting the stone, especially in calking.

The diamond setter will find it to his advantage to study Fig. 3, in which are illustrated the forces to which a diamond in the bottom surface of the bit is subjected. The forces of outside application are due to the thrust or weight of the drill rods and the rotation of the bit. The tendency of these forces is to rotate the stone in its setting. The irregularities of the diamond, and the seat formed for them, resist the rotation. The arrows *A*, *B* and *C* in Fig. 3 indicate the direction of the forces acting on the diamond.

Determination of the best position in which to set a given stone does not admit of fixed rules, but is based upon experience and experienced judgment. Different diamond setters will agree that there is one position in which a given stone can be set and in which it will be safely held and will cut with minimum wear.

GERMANY THINKS IT A CRIME to seize her mines. She doesn't believe in anything more drastic than dynamiting and flooding.—*Muskogee Phoenix.*

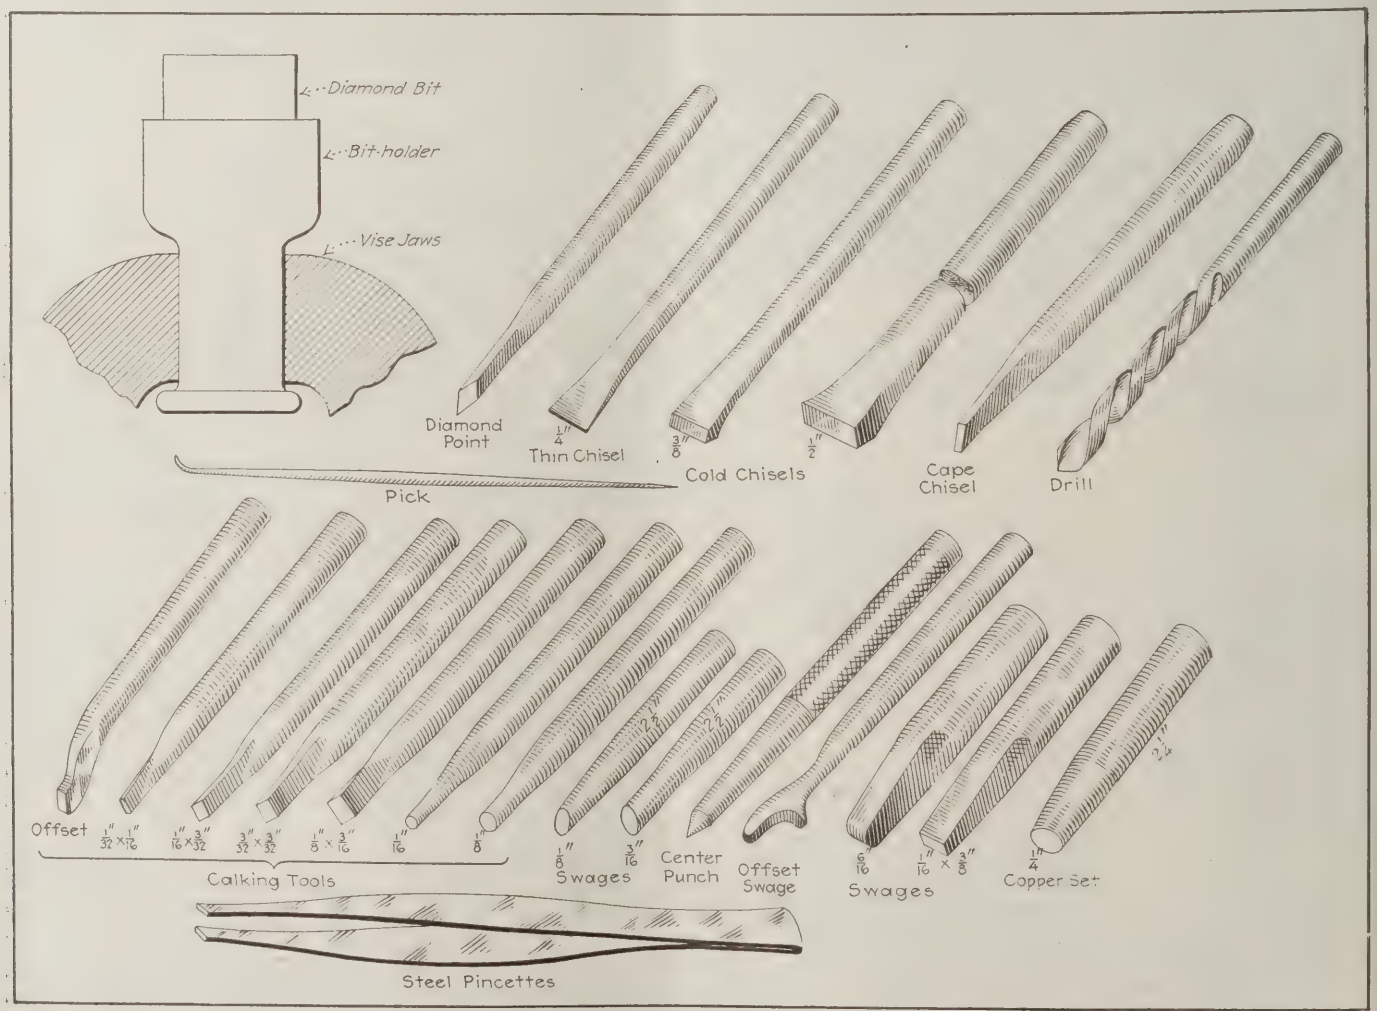

FIG. 4—TOOL KIT OF DIAMOND SETTER

In the upper left-hand corner are the jaws of the vise holding the bit holder so that the bit can be drilled. To the right are the chisels which condition the hole for the reception of the diamond. Below it are the calking tools which fit the copper round the diamond and the swages that push the steel so as to envelope both. At the base of the drawing are the steel pincettes which are used in the handling of the small copper chiselings for insertion between the diamond and the walls and bottom of the hole.

Biggest Asiatic Coal Producer and Thickest Coal Seam In the World at Fushun, South Manchuria

Will Extract Enough Material to Girdle Earth at Equator with Solid Wall 29 Ft. High and 10 Ft. Thick—Coal 430 Ft. Thick at One End of Field—In Places Only 30 Ft. Below Ground

By W. Laurie Seaman
Glen Cove, N. Y.

MANY observations of interest made during a trip to the Fushun colliery and some views of the mines obtained from the South Manchuria Railway Co. profitably may be added to the remarks and illustrations presented by N. Yamaoka in his excellent articles in *Coal Age*, May 19 and May 26, 1921. Only slowly can a mere article bring home to the reader this amazing coal property, its total content of 1,200,000,000 tons, the immense thickness of its single seam, which at the western end is 430 ft. thick, and its suitability in places for stripping, its cover in one place being only about 30 ft.

The Fushun coal field of Manchuria, with a daily output of 12,000 tons, is situated about 35 miles southeast of Mukden and covers barely 15 square miles. Forming a narrow rectangular area 10 miles long and running along the valley of the Hun River in an eastward direction, the main coal deposit consists of but one 50- to 180-ft. seam with an average thickness of about 150 ft. At the western end it grows even thicker, reaching 430 ft. and is found in one place but 30 ft. below the ground surface. Seldom is such an abundance of potential energy found in so small an area, especially in a single seam.

Electric Hoists Pull Wagons Out of Pit

That portion of this coal field which lies close to the surface is mined by the highly efficient open-cut process, which consists of stripping off the overlying materials and shoveling the coal into wagons which are drawn by electric hoists up inclined roadways to the edge of the strip pit. If the coal and overburden that has been excavated in the past and will be removed before the field is exhausted were piled around the earth at the equator it would make, so estimators have calculated, a solid wall 29 ft. high and 10 ft. thick. In other words, this gigantic undertaking will require 5.4 times as much excavation as was necessary for the digging of the Panama Canal.

The Koreans were the first to obtain coal from this region. That was some 600 years ago. It was used by them in baking their famous earthenware. After the occupation of Manchuria by the Chinese, which took place about 200 years ago, mining was entirely suspended, its continuance being prohibited by the Chinese Government because of a superstitious belief in the Fengshui, or Spirit of Nature. It appears that Fushun was situated too close to the mausoleum of Tai-Tsu, an emperor of the Manchu Dynasty, to meet with divine approval.

During the Russo-Japanese War the mines were worked on a small scale by the Russians, but not until 1907, when the South Manchuria Railway Co. acquired this property from the Japanese Government, was mining undertaken on an extensive scale. Shafts were sunk annually until there were eight in all, which in conjunction with the strip pit, are producing 3,500,000 tons yearly.

The visitor, after traveling over the level plains of Manchuria, on pulling into Fushun station is filled with awe to see the immense chasm that was filled with earth and coal but a few years ago. The steam shovels working in the vast pit look like mere toys and the hundreds of coal wagons and thousands of Chinese coolie miners are but moving specks within the depths of this artificial valley, which already has attained the size of the celebrated Culebra cut where the Panama Canal pierces the backbone of the Americas. After coal has been removed for a period of 70 years at a possible output of 10,000 tons (equal to a train of 250 cars) each working day only a romantic mind will be able to imagine its original appearance.

My train was nearly two hours late in reaching Fushun, allowing me only a hurried trip around the colliery. After a study of charts and maps and a "swell" lunch at the Colliery Club, we set out to see the sights before my predetermined return to Mukden on the afternoon train. As the Japanese are anxious to receive world comment, either favorable or adverse, on their activities in South Manchuria, I found them quite ready to furnish me with any information that I might desire.

The underground mines were first worked with shafts and the room-and-pillar system, but the mining engineers soon discovered that, if this plan of operation were persistently followed, 70 per cent of the coal must be left underground, to serve as roof and shaft supports and the like. Experiments proved that by replacing coal with sand, flushed in by a hydraulic stowage system, thus furnishing the necessary support for side walls and roof, 70 or even 80 per cent of the coal could be removed, thereby greatly increasing the efficiency and capacity of each shaft.

Fourteen Large Flushing Plants Fill Mines

Fourteen huge flushing plants were placed in operation by 1920. The Japanese engineers mix just enough water with the sand to form a flowable mass, which is forced under pressure of 10 atmospheres through pipe lines to chambers already barricaded and ready to be packed with sand. A minimum volume of water is used, as it must be pumped from the mine after serving its purpose of stowing the sand in the various subterranean passages.

In 1919 more than 7,800,000 pieces of mine timber were consumed in the Fushun Colliery. This number was materially lessened in the years that followed, the introduction of the hydraulic stowage system permitting much timber to be recovered as the sand flushing progressed.

The town of Fushun sprung up as the natural out-

come of the mining activity and the operating company in consequence was compelled to construct hundreds of buildings, highways, water works and other conveniences.

Most of the mine workers, and 35,000 of them are employed, are Chinese from the Shantung and Chihli districts of north China. They receive free lodging and medical attention, three rationed meals at 14 sen (7c. U. S. currency) per day and are paid an average daily wage of 55 sen for nine hours work. Assuming a year as 250 working days, their annual earnings total nearly 140 yen ($70 in U. S. currency).

Fully 60 per cent of the Fushun coal is consumed by the railway in Manchuria, and the remainder is either sold to local industries or exported through the port of Dairen. Prominent foreign engineers and mining experts have gone away from Fushun marvelling at the equipment and layout which the South Manchuria Railway Co. has inaugurated during the fifteen years of its management.

Consumption Should Control and Determine Number and Ownership of Coal Cars

By L. S. Evans*
Richmond, Va.

BITUMINOUS coal is produced as the market demands it, save as transportation, or at intervals miners' strikes, interfere. Demand is measured by two elements, requirements for consumption plus or minus coal for or from storage. Transportation is the great factor in leveling off peaks of production and setting the brake on output. The soft-coal mines have developed capacity more than ample to meet consumption.

Since the potential supply is superabundant and the aggregate productive capacity of the mines exceeds consumption, it follows that transportation is the controlling and limiting factor in balancing production with consumption.

The only storage of coal at the mines is the natural supply within the earth. Coal loaded in mine cars underground is carried to the mine mouth and dumped into railroad cars. When no cars are supplied the mines stand idle. With transportation the dominant factor there is no advantage in storing coal, even where possible, above ground at the mines. The place to store coal is at the point of consumption.

Railroads reaching the mines are expected to own coal cars in numbers sufficient to supply the country's needs, hence the coal roads must bear the financial burden of such ownership and upon them falls responsibility for transporting the country's coal supply. These coal originating roads buy and maintain equipment either in anticipation of the annually constant increase in consumption or after the increase has occurred. For financial reasons, equipment purchases commonly are made after the need has arisen and car shortage has appeared.

Here is a remedial suggestion: let consumption control and determine the number of cars and their ownership. Consumption comes first; it sets the need for production. Every railroad should own that number of coal cars required to protect the consumers it serves. The number of cars owned by each should depend mainly upon the tonnage consumed on its line. In practice, empty cars would move to coal roads counterbalanced by loaded cars from the coal roads. Car shortages would seldom occur, and only on the underequipped roads. Many roads, instead of a few, would own the cars, and this distribution of the financial burden would make it easier to maintain equipment at the point of adequacy.

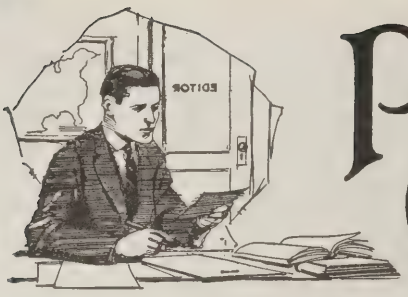
Box cars carry the widest range of commodities and are used everywhere, therefore all roads own box cars. Whether or not consumption or production governs the ownership of box cars is not the point: the fact that all roads own them means that there is a constant interchange of cars of the same kind. This condition tends to balance car movements and to prevent national shortages by localizing them.

Coal cars are not generally useful and they are not generally owned. Coal-originating roads are almost the exclusive owners of coal-carrying equipment. Some roads own coal cars to protect the fuel supply for their locomotives, but apparently none has considered such ownership for the protection of its industries and other consumers along its lines.

The coal roads send out loaded cars to various destinations on connecting lines, there to be unloaded and returned empty to the parent lines for reloading. They are in effect interchanging their own equipment, which means that they must own sufficient cars to supply the consumers on all lines plus their own.

Under existing conditions how can there be a balanced movement of coal cars even approximating the interchange of box cars?

*Eastern Coal & Export Corporation.



Engineers Stress Advantage of Storage to Early Movement of Domestic Coal

IN URGING engineers to take up with their employers and clients the advisability of effecting an earlier movement of domestic coal—a step taken at the request of John Hays Hammond, chairman of the President's Coal Commission—the Federated American Engineering Societies has addressed a letter to its member societies, of which the following is a part:

Mr. Hammond stated that one of the important factors involved in the solution of the coal situation is that of coal storage. He further stated that it is a more difficult task to obtain the storage of domestic coal than that of coal purchased by large users. He is particularly anxious, therefore, that an effort be made at the earliest possible moment to obtain a larger storage of domestic coal. He believes that the engineers of the country are in a particularly advantageous position to encourage this movement. If engineers will point out to their clients and employers the advantages, accruing both to the public and to the coal industry, which can be obtained if coal is stored during the summer, it is believed that they will be willing to arrange for the domestic coal purchases of their employees.

The Coal Commission is particularly impressed by the plan devised by L. S. Storrs, of the Connecticut Company. Under that plan the employee submits, prior to April 1, an estimate of his winter fuel needs. Delivery is to be made at the option of the retail dealer during the six months' period beginning with April. Full payment for the coal will be made by the company at any time delivery is effected.

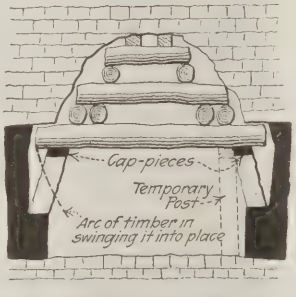
The company is reimbursed by deducting the cost of the coal from the employee's salary. These deductions, however, are spread in equal installments over the six months' period. Under this plan the employer can see to it that the coal is purchased at the best possible price. He can influence the dealer to deliver the maximum practicable amount of coal early in the season. The employees, many of whom are accustomed to buying coal in very small lots during the period of highest prices and distribution difficulties, can make substantial savings, and be assured of sufficient quantity of coal when needed.

Problems of Operating Men

Edited by James T. Beard

Retimbering an Old Slope

Two Methods Discussed—First, Gives Insufficient Support to Timbers Above — Second, Has Short Legs Hitched Into the Coal



REFERRING to the problem presented in the inquiry signed "Mac," which appeared in *Coal Age,* March 1, p. 380, it occurred to me, in reading his letter, that both of the methods suggested for the retimbering of the old slope where the roof had fallen to a considerable height, could be improved.

The first method he mentions, using double timbers and supporting the collar on two legs set on the bottom is, in my opinion, very poor. Even if the bottom is hard and furnishes a good foundation for the legs, the use of double timbers on this 8-ft. slope is not to be recommended. In that method the legs stand out where they will be struck by the first car that jumps the track. This would mean a downfall of roof and tangled timbers requiring time to clean up and retimber.

If the bottom is hard, cap-pieces should be used over the posts. In fact they will serve a useful purpose in any event, as they assist to wedge the upper timbers and lagging tighter against the roof. For these reasons, I would set aside this first method as being in no way adapted to the situation.

Suggests Supporting Collars on Short Legs

The second method suggested, in which the collar beam is supported in hitches cut in the two ribs, strikes me as a great improvement over the first. However, let me suggest that the use of short posts resting in hitches cut in the coal, after the manner shown in the accompanying figure, will prove an advantage provided the coal is hard as I assume it is in this case.

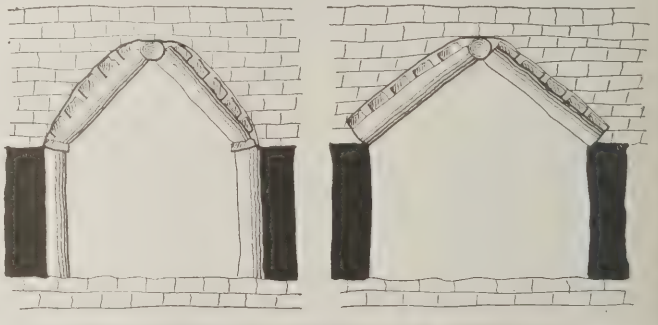
COLLAR BEAM SET ON SHORT LEGS

The statement that the weight is breaking the timbers and the frail soapstone overlying the seam, and nothing being said in regard to the crushing of the coal, leave me to conclude that the coal is hard and will offer a good support for short posts used to support the collar beams.

The short posts will not add materially to the cost of the timbering, as compared with the method of supporting the collar beams in hitches cut close to the roof. The roof hitches would have to be cut wide enough to permit the collar beams to be swung into position. On the other hand, the cutting for the short legs will be no greater in amount and more readily made.

The length of these short posts will be governed much by the nature of the coal seam, as the posts should be set on that part of the stratum furnishing the firmest support. As shown in the figure, the posts should be inclined slightly toward the center of the opening, so as to throw the weight of the overburden into the rib.

As indicated by the dotted lines in the figure, a temporary post can be used, if needed to support the collar beam, while putting the timbers in place. At times, if desired, a short post may be set on one side of the entry only, the other end of the collar beam then being supported in a hitch cut in the rim, after the manner suggested by the correspondent.



Fairmont, W. Va. M. L. O'Neil.

Another Letter

Herringbone method of timbering—Two plans suggested—Steel and concrete for support of ribs.

WHEN reading the inquiry signed "Mac," *Coal Age,* March 1, p. 380, it seemed to me that there would be nothing better for his purpose than the herringbone method of timbering. I have always found that method to give excellent results in the support of bad roof and particularly, in a case like this, where the roof has fallen to a considerable height.

In the use of this method, I have two plans to suggest, as shown in the accompanying figure. The plan

TWO FORMS OF HERRINGBONE TIMBERING

on the left of the figure, however, is open to the objection that the two legs forming a timber set crowd the entry and are liable to be knocked out by a derailed car. For this reason, I would only use legs for the support of the timbers in cases where the coal was very soft or it was impracticable to employ the method shown on the right of the figure.

By that method the two roof struts butt into the solid strata just above the coal seam, which gives them a firm support and leaves the roadway clear of all obstruction. In both of these methods, longitudinal stringers are used at the crown and are held in position by the diagonal roof struts, as appears in the figure. Lagging is used behind the roof struts, for the support of the loose material between sets.

In particular cases, where support must be given to the soft coal forming the ribs, I would use steel props and longitudinal girders. Between each prop a

form should be built and the space behind filled with concrete, which makes a permanent job. I have used these methods a great deal, particularly in longwall work where the roof above the roads had fallen to a considerable height. W. DICKINSON.

Bay City, Mich.

Relative Danger in the Working of Non-Gaseous Mines

Discussion not complete without considering the non-gaseous mines—Local explosions in those mines a twofold danger—Excessive use of blasting powder another danger.

RECENT issues of *Coal Age* have contained numerous letters relating to mine explosions and their prevention. While I am compelled to agree with what has been said by these correspondents, my feeling is that the discussion is incomplete, unless it considers alike the dangers of both gaseous and the so-called "non-gaseous mines."

Indeed, I often think that the gaseous mine is frequently the safest in respect to liability of explosion. At the present time, so much attention is given to the system of ventilation and the elimination of conditions that invite explosions of gas or dust, that there is little to fear, except from a possible accident to the system, or failure of some official to perform his duty.

TWO-FOLD DANGER IN LOCAL EXPLOSIONS

Of course, local explosions of gas in working places are chiefly confined to those mines known to be generating gas. At times such mines are worked with locked safety lamps and, again, open lights are permitted where an ample air current is in circulation. These local explosions are twofold in character. First, there may only result the severe burning or death of one or more men working in the place; and, second, the flame may be extended throughout the mine with terrible effects.

As has been previously remarked by George Edwards, the total of these local explosions is greater than is generally thought; because they are given no publicity, in comparison with the accounts that are broadcasted when a great mine disaster occurs. However, the second danger mentioned is not to be ignored, which consists in the liability of such a local explosion being propagated throughout the mine.

Taking these things into consideration, it is clear that we cannot afford to minimize the danger of a local gas explosion. In one respect it is true that the gaseous mine is more dangerous than a mine generating no gas, or in quantities so small as not to justify any alarm. The point I wish to emphasize, however, is that where a mine is well managed the danger arising from the presence of methane in the workings can be greatly reduced by proper ventilation.

COAL DUST MOST DANGEROUS FACTOR

Now, let me turn to another phase of the situation; namely, the danger of a coal-dust explosion. Probably, the most dangerous factor in this regard is the improper use of explosives. In most gaseous mines that I have visited, there are strict regulations relating to the use of explosives and the blasting of coal and rock.

On the other hand, in many non-gaseous mines we find the miners are the sole judges as to what is safe or unsafe in blasting. There is little restriction placed on the amount of explosive used in preparing a shot. Black blasting powder is employed and excessive charges are used with the idea of breaking the coal into smaller fragments so that it will be easier to load.

Even in machine mining, it is not uncommon to find the holes bored deeper than the cut and the charge located on the solid. The danger is all the greater when such a hole is tapped with coal dust. Surely, it should cause no surprise when such conditions as these result in an explosion; and it cannot be denied that these and other dangerous practices are followed, daily, by many miners.

It is not my claim, however, that all or even a majority of our miners are guilty in this respect. Nevertheless, if one miner out of a hundred at work in a mine takes a chance and an explosion follows, all the safety precautions that the remaining ninety and nine may take will not render them safe.

DANGEROUS PRACTICES COMMON AMONG MINERS

In this connection, let me mention a few other dangerous practices common in many mines. Briefly, these are the mixing of different grades of powder in the same hole; the use of too short a fuse or breaking off a part of the match on a squib; the firing of two or more shots, at the same time, in a close place and many like things that miners have been warned are dangerous.

My experience has been that such practices as these are more common in non-gaseous mines owing to the absence of strict rules and regulations in respect to blasting. To my mind the greatest need today is the enactment of certain laws that will apply to all mines whether or not they liberate explosive gas. Among these should be included the exclusive use of permissible explosives; the prohibition of solid shooting and providing for the firing of all shots by certified shotfirers. I believe this would eliminate one of the greatest dangers common to all non-gaseous mines.

Welch, W. Va. SAFETY INSPECTOR.

Correct Position of Regulator

Would place regulator on inby side of overcast—Danger of leakage into intake current much lessened—Position must be convenient and accessible.

ALLOW me to make a suggestion in regard to the position of the regulator shown in the figure illustrating the inquiry of James Bacon, *Coal Age*, Feb. 22, p. 341. In that figure, the regulator is shown in a position to the left, or on the outby side of the overcast.

If my understanding is correct, the right entries shown have been taking too much air and it was necessary to install a regulator to restrict the circulation in that pair of headings. As stated in the reply to this inquiry, the regulator should be placed "where it will not interfere with the hauling of coal."

In the present instance, no doubt, this requirement will place the regulator on the back entry. The reply states that it can be located on either side of the overcast. Allow me to suggest that it should be placed, preferably, on the inby or opposite side from that shown in the figure.

My reason for suggesting this change is that the air bridge would then be on the outby side of the regulator and subject to a less pressure. Should any leaks develop in the overcast, there will then be less of the return air escaping into the intake current than

would result with the regulator in the position shown in the figure, or when the air bridge is on the inby side of the regulator.

It is true that the difference in pressure and the amount of leakage will generally be quite small. It must be remembered, however, that a very small percentage of gas is a dangerous factor in respect to the dust question. For that reason alone, every possible precaution should be taken to prevent the contamination of the intake current with the gas in the return.

Linton, Ind. W. H. LUXTON.

Employment of Oriental Miners in Pacific Coast Mines

Misstatement of facts regarding employment of Oriental miners in Pacific Coast mines—Official figures show relatively small number.

IN the issue of *Coal Age* Feb. 8, p. 268, J. W. McBride of the Cinnebar Coal Mine, Bremer, Lewis County, Wash., writes informatively of the Pacific coal industry. With regard to the accuracy of certain statements attributed to the U. S. Coal Commission, the American Mining Congress and other authoritative sources to the effect that "there are one-third too many coal mines in operation," I have nothing to say.

In refuting this claim, however, Mr. McBride, after reviewing the production and consumption of coal in the West and Northwest, makes a brief reference to the class of miners employed in the mines of the Coast. He says: "The majority of the coal miners on the Pacific Coast of British Columbia are Japs, Chinese and Hindus—in the United States, all whites."

In this respect, the facts are that, according to the official figures for the year 1921, of the total number of men employed in and around the coal mines of Vancouver Island, 17.227 per cent were Orientals; while the percentage of Orientals employed underground was only 15.12. No Hindus were employed in these mines.

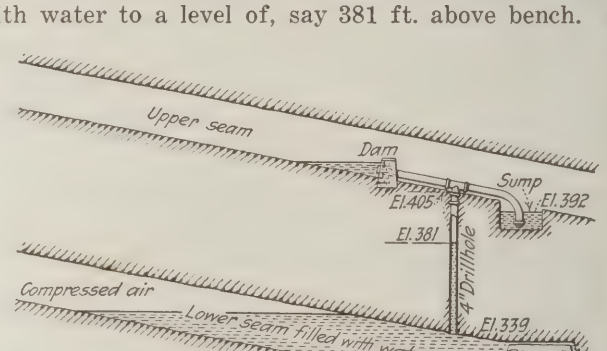
It is only fair to the Vancouver Island Industry, and to all associated with it, employees and operators, that Mr. McBride's sweeping and fallacious statement should be corrected. If allowed to go unchallenged its effect would be harmful, which I am sure the writer does not desire; nor would he wish to be responsible for such a result.

No doubt, the publication of the official figures for the year 1921, will serve to allay any misunderstanding that might exist in the minds of many who read the first article. The following table gives the number and race of the employees of the principal collieries on the Island of Vancouver:

	Number of Men Employed						
	Underground				Aboveground		
Name of Colliery	Whites	Indians	Chin.	Jap.	Whites	Chin.	Jap.
Western Fuel Corporation of Canada	1,112	3	0	0	504	109	0
Nanoose-Wellington Collieries	197	0	0	0	37	0	14
Granby Consolidated Mining, Smelting & Power Co.	344	0	0	0	132	0	0
King & Foster	17	0	0	0	10	0	0
Canadian Collieries (D) Ltd.	1,174	0	430	0	459	272	0
Pacific Coast Coal Mines	0	0	0	0	4	6	0
Total	2,844	3	430	0	1,146	387	14

Total number of men employed in and around the coal mines, on Vancouver Island, for the year 1921: Whites, 3,990; Indians, 3; Chinese, 817; Japanese, 14. Total, 4,824. These are official figures. R. D.

Victoria, B. C., Canada.



Inquiries Of General Interest

Pumping Phenomenon

Draining an Upper Seam Through a Drillhole Into a Seam Below Develops a Surprising Phenomenon for Which an Explanation Is Asked

IN THE mine where I am employed there is a 4-in. drillhole, sunk from the upper to the lower seam for the purpose of draining all the water into the seam below, or dewatering the upper seam at small expense. At this point both seams have an inclination of about 10 deg. All chambers are connected by crosscuts or breakthroughs and, about 300 ft. from the chamber in which the drillhole is located, some of the chambers have been driven through to the surface.

At the present time the lower workings are filled with water to a level of, say 381 ft. above bench. As

ILLUSTRATING A DRAINAGE PROBLEM

shown in my sketch, the corresponding elevations of the bottom and top of the drillhole are 339 and 405 ft., respectively, while the water level in the sump in the upper seam is 392 ft., or 13 ft. below the top of the drillhole.

There has been set in the rock, at the top of the drillhole, a 3-way connection, leading to the sump, the drillhole and a catch basin formed by a dam erected a short distance up the pitch from the drillhole, to collect the water coming from the upper levels. A pump is used to pump the water from the sump below the drillhole into the hole.

The point of interest that has puzzled us and which we would be glad to have explained is the following: Normally, the water in the drillhole rises to a height of 24 ft. below the top of the hole, which shows the elevation of water level in the old workings below 405 — 24 = 381 ft. But, after pumping the water from the sump below into the drillhole, say for five hours, when the pump is stopped the water will spout from the pipe leading to the dam and continue to flow for 2 or 3 hr. before it will slow down and finally cease. Following this action the water above the dam will then drain back into the drillhole where it will finally sink to a level of 381 ft., as before. PUMPMAN.

Mocanaqua, Pa.

Under the conditions explained in this inquiry there is nothing strange in the spouting back of the water,

after the pump has ceased forcing it down the drillhole into the old workings. In order to understand the situation, it must be remembered that the old workings are driven to the rise; and, while some of the chambers are said to have been driven through to the surface, there are doubtless others that form an airtight pocket at the head of the chamber where the rising water compresses the air after the water level has once reached the roof at the mouth of the chamber.

Under these conditions it is easy to see that the air in a number of these chambers is compressed to a pressure equal to the pressure due to the action of the pump, plus the head of water, as determined by the difference in water level in the chamber and the top of the drillhole. Naturally, when the pump is stopped this pressure acts to force the water through the pipe leading to the dam, under a pressure equal to that caused by the pump. The flow will continue until the compressed air has expanded to an amount that will just support the water column reaching to the dam. Beyond this point, as the water drains off gradually, in the old workings in the lower seam, the water level in the drillhole will again assume a normal position.

Examination Questions Answered

Alabama First-Class Examination, Birmingham, Jan. 22, 1923

(Selected Questions)

QUESTION—*What are the duties of a mine foreman? Explain fully.*

ANSWER—A mine foreman must devote all of his time to the supervision of the mine in his charge. He must reach the mine each morning in time to examine and sign the fireboss' report and see that no men enter the mine whose places are reported as unsafe for work, until the dangers reported have been removed, the places examined and found safe for work. The foreman must give his particular attention to the ventilation of the mine, the proper distribution of the air and the removal of all dangers that are reported to him.

The foreman should employ and assign work to such men as he finds are capable and fit for the work in hand. He must investigate all alleged violations of rules and ascertain as nearly as possible the causes of any accidents that may occur in the mine and the person or persons responsible for them. He must make out a full report of such accidents to be sent to the mine inspector in charge of the district. In a few words, the mine foreman is responsible for the safe and economic working of the mine in compliance with the mine law; and it is his duty to enforce all rules and regulations.

QUESTION—*Of what use is a correct map of a mine to the foreman?*

ANSWER—Such a map would enable him to plan all work on an intelligent basis and avoid the loss of much coal that will always result when entries and rooms are driven blindly or without the giving of sights to determine the direction of driving. If complete, the map will show many physical features that will enable the foreman to avoid running into danger.

QUESTION—*What are the dangers and the consequent results arising from not having accurate and complete surveys of the workings of a mine?*

ANSWER—One of the chief dangers is that of the near approach to old abandoned workings that may contain accumulations of water or gas. A body of water confined under a considerable head is a hidden danger that should be made known through careful and accurate surveys. The information conveyed to the foreman by an accurate map will enable him to avoid the danger present when driving under waterways or reservations for the prevention of damage to improvement on the surface. A wise foreman will always exercise special precautions under such areas, by leaving wider pillars and adopting methods of timbering that will prevent undue settlement and breaks that may extend to the surface.

QUESTION—*If when making an examination of a mine, you found a large body of explosive gas, state what precautions you would take to prevent an accident from same?*

ANSWER—If the discovery is made when the men are at work in the mine, no attempt must be made to disturb the gas, until after the men have been notified and withdrawn from the workings. Immediate steps must be taken to safeguard all entrances to the place or places where the gas is confined. Reliable men equipped with safety lamps must be placed where they will be able to prevent any person from entering such areas, until the danger has been removed after all the men have departed from the mine, and until the section has been finally examined and found safe.

QUESTION—*If a mine of which you had charge should suddenly develop firedamp, what would you consider your duty, according to the laws of Alabama?*

ANSWER—In such a case, the Alabama mining law (Sec. 11) provides that immediate notice be sent to the chief mine inspector and the inspector of the district, by the operator in charge of the mine. It is the duty of the foreman, therefore, to promptly notify the superintendent or manager of the mine, regarding the condition he has discovered. Having done this, his responsibility under the law ends, as far as notifying the inspection department is concerned. However, the foreman must still do everything in his power to safeguard the men, by withdrawing them promptly from the mine, by the safest route possible. He must then, in company with his firebosses, take charge of the work of removing the gas and making the mine safe.

QUESTION—*What is a safety lamp and why is it safe?*

ANSWER—A safety lamp, so-called, is a lamp whose flame is isolated from the outside atmosphere by means of a wire-gauze chimney and a similar gauze protecting all entrances for air openings to the lamp. Such a lamp, however, is only safe when properly handled by a competent person who understands its principle of construction and knows the danger of violating those principles by improperly handling the lamp or exposing it to a strong current or blast of air, or allowing the gauze to become heated or clogged with dirt.

QUESTION—*How many apertures are there in a square inch of the standard safety-lamp gauze?*

ANSWER—The wire mesh adopted as standard, by American and English safety-lamp manufacturers, is based on the experiments of Sir Humphry Davy, who found that the greatest degree of safety was insured by a mesh having 784 openings to the square inch, formed by 28 wires (No. 28 B.w.g.) to the inch.

Coal Wholesalers Issue Summary of Massachusetts Pure Coal Law

The Massachusetts Pure Coal Law, a recent enactment, is summarized by the American Wholesale Coal Association as follows:

Who Enforce the Law.—(1) Department of Public Health. (2) Local Board of Health. (3) Director of Standards. (4) Local sealers of weights and measures. (5) Or the agents or employees of any of them.

What They May Do.—(1) Enter each place where coal is stored or kept for sale. (2) Enter railroad trains, cars or any vehicle used to haul coal. (3) Inspect such coal and take a sample for analysis. (4) Analyze, inspect or otherwise test such coal. (5) Record and preserve as evidence the result of such tests. (6) If in the opinion of any of the several authorities the coal so tested is unfit for ordinary use they may (a) condemn, (b) destroy, (c) dispose of otherwise than for ordinary use.

Penalties.—(1) For interfering in any way with the designated officers in enforcing the law, a fine of from $100 to $1,000, or imprisonment from one month to one year. (2) For having possession of, with intent to sell, selling, exposing or offering for sale coal which has been condemned, a fine of from $100 to $1,000 and or imprisonment from one month to one year. (3) For having possession of, with intent to sell, selling, exposing or offering for sale coal unfit for ordinary use, a fine of not more than $1,000 and or imprisonment for not more than one year. (4) For placing any foreign substance in any container with coal, for selling, exposing or offering for sale, or having possession, with intent to sell coal packed in receptacles containg any unreasonable amount of foreign substance, a fine of not more than $1,000 and or imprisonment for not more than one year. (5) For violating any provision of the act, or failing to comply with any request for information, or direction of the authorities, or for giving a false answer, a fine of not more than $50. (6) For fraud or deceit as to weight, for selling coal which is short in weight or measure, or contains an unreasonable amount of impurities, a fine of not more than $1,000 and or imprisonment for not more than one year.

It will be noted, says the bulletin of the wholesalers, that there is no absolute measure established by the law for the determination of the amount of slate, other impurities, etc., and that the whole matter is left to the judgment of the several local officers. There may be as many different standards of purity as there are officers attempting to apply the act.

A. J. Hoskin Succeeds the Late Dr. Stoek as Head of University Mining Department

Arthur J. Hoskin, research assistant professor of mining, has been appointed acting head of the department of mining, University of Illinois, to fill the vacancy caused by the sudden death of Dr. H. H. Stoek, founder of the department of mining at that institution.

The following is a summary of Professor Hoskin's thirty-three years of experience in mining and metallurgical work. After being graduated from the University of Wisconsin in 1890 he went immediately into active mining work, as assistant to a mining engineer at Idaho Springs, Colo. This work covered mineral and patent surveys and mine development. He then became assayer for the Omaha and Grant Smelter at Denver and selling agent for twelve of the mines at Cripple Creek and Leadville. For one year he was engaged in the U. S. Surveyor General's office at Denver, later becoming consulting engineer at Leadville. Here he received his coal-mining experience and from 1903 to 1906 he was chief engineer for the Leyden Coal Co., opening and operating one of its mines in a new district, near Denver. He designed and erected the first automatic coal machinery, such as cagers, weighers, box-car loaders, etc., used west of Iowa. He received the degree of mechanical engineer from Wisconsin on the basis of his experience and thesis on the mechanical equipment of the Leyden coal mine.

A. J. HOSKIN

For two years he was assistant professor of mining at the Colorado School of Mines, then full professor for four years at the same institution, which at that time was the largest mining school in the country. At various times during his six years at that institution he taught every course in the mining curriculum, introducing courses in coal mining, which before that time had not been taught in that college. He was in business for himself in Denver from 1917 to 1920, and then became mill superintendent for the Colorado United Mines Co.

He edited for a while the *Mining and Metallurgical Journal*, Denver, and the *Mining American*, which later merged with the *Mining Record*. He then became Western editor of *Mines and Minerals*, at the same time that Dr. Stoek was the Eastern editor.

Since going to the University of Illinois in 1921 he has made an extensive study of Illinois coal-mining problems, has visited every mining district in Illinois, both coal and metal, and is now completing important research in power costs in Illinois coal mining.

Utilities Consume 3,251,097 Tons of Coal In February; Decline Due to Short Month

Electric public-utility plants consumed 3,251,097 net tons of coal during February, according to a report just issued by the U. S. Geological Survey. This compares with 3,561,236 tons consumed during January, according to corrected returns.

Fuel oil consumed by public-utility plants in February totaled 1,166,203 barrels, compared with 1,256,604 barrels in January and 1,306,930 barrels in December, 1922.

The average daily production of electricity by public-utility power plants continues to break all records, as the average production in February was about 1½ per cent greater than that for January. February is the seventh consecutive month which has established a new record of average daily output. All indications at the present time point to 1923 being a remarkable year in the production of electricity. The average daily output of electricity during February was 155,300,000 kw.-hr. compared with 153,200,000 kw.-hr. during January.

W. L. Abbott Is Chairman of Federated Engineers Coal Survey Committee

W. L. Abbott, of Chicago, has been appointed chairman of a committee to make a nationwide coal storage survey in co-operation with the U. S. Coal Commission and the Department of Commerce, according to an announcement by the Federated American Engineering Societies. Other members of the committee will be named in the near future. It is probable that the personnel will represent many groups, including coal mining, both bituminous and anthracite; transportation, public utilities, U. S. Bureau of Mines, chemical engineering, economics and equipment. It is proposed to complete the survey by Nov. 1 of this year.

Mr. Abbott is a member of the American Institute of Electrical Engineers and has been a leader in the engineering movement for government reorganization sponsored by the National Public Works Department Association.

Anthracite Operators Brand 1922 Strike as Hold-Up In Flagrant Violation of Anti-Trust Laws

Unless some remedy can be found "whereby force can be dethroned and reason recognized as ruler," anthracite operators contend in a brief filed with the Federal Coal Commission and made public April 16, there is "no salvation for the anthracite industry."

After reciting in detail the events leading up to the strike of 1922 the statement, signed by Walter Gordon Merritt, counsel for the operators, asserts that "this national hold-up, by refusing to negotiate with willing union operators with whom there was no dispute, by disrupting non-union operations, by avoiding an anthracite settlement, by flouting the President of the United States, and by refusing to arbitrate, had for its purpose the attainment of its ends by ruthlessly inflicting injury on the public, in flagrant violation of the federal Anti-Trust laws.

"The refusal to permit resumption of coal production by the producers of 90 per cent of the nation's coal supply, on any terms within the reach of the parties, was not to bring pressure on these producers to grant more concessions but to starve the public into submission through a protracted coal famine.

"The purpose to extend the power of the United Mine Workers by international combinations to deprive the American people of coal is clear if the report from London under date of April 12, 1923, is true, that President Lewis has offered a resolution before the Executive Committee of the International Federation of Miners declaring 'in case of strike all means should be taken to prevent export of coal to the country involved in strike.'

"Throughout the trying days of 1922 the operators were fighting for the principle of settlement by reason, and the mine workers were fighting for a settlement by force. The operators stood for arbitration in an industry of great public importance. The miners stood for coercion by public privation. In the end the demands of a frightened public, supported by the urgings of public officials, led to a sacrifice of the principle in order that the public might have coal.

"Unless that chapter of history can be reversed, unless the commission can find some remedy whereby force can be dethroned and reason recognized as ruler, there is no salvation for the anthracite industry. Nearly all other questions are subordinate to this. It is not as a wage-adjusting body that this commission can best serve its country but in establishing durable and workable machinery for the adjustment of peaceful methods of all differences that may hereafter arise and the elimination of industrial warfare.

"The strike is a legitimate weapon to drive an economic bargain with a selfish employer, but there is no moral right, and should be no legal right, to organize strikes or lockouts in basic industries or transportation where disinterested agencies for adjustment and adjudication are available.

"A national combination, controlling coal production, whether it be of employers or employees, which disregards the public interest and wilfully seeks to produce a coal famine by refusing to arbitrate industrial disputes, deserves correction and regulation at the hands of government. A government which is unafraid can do no less than meet this issue. If society has a right to protect itself against abuses in the coal industry, here is occasion to act. If this major problem goes unremedied, there is no consistency in proposing remedies for minor problems."

Mining Maps Need Not Be Shown to So Called Experts for Boosting Tax Valuations

Judges Strouss and Lloyd, in the Common Pleas Court of Northumberland County, Pennsylvania, have concurred in an important decision, ruling that mining maps do not have to be shown to alleged "experts" engaged by County Commissioners for the purpose of boosting coal-land valuations.

This is said to be the first clear-cut decision rendered on this particular issue. The inference which an outsider would draw from the whole proceeding is that the "experts" merely guessed at coal-land values, and then tried to compel their prospective victims to furnish information whereby they could bolster or correct their findings, or slide out gracefully, as the case might be.

As the decision of Judges Strouss and Lloyd is likely to serve as a precedent in similar anthracite tax proceedings, and in particular seems likely to cut some figure when the tax appeals come up soon in Schuylkill County, the complete opinion, rendered in the action of the Philadelphia & Reading Coal & Iron Co. vs. Commissioners of Northumberland County, is given herewith:

"This proceeding is before us at this time upon a petition and rule to show cause why an order should not be made permitting the Commissioners of Northumberland County by their counsel and engineers to have access to the records and the mines of the plaintiff company. The rule has its inception in an appeal from the action of the Board of Revision in assessing the real estate of the plaintiff company for taxable purposes. The rule has been pending for some time and when called for argument in open court, counsel for the Commissioners of Northumberland County appeared and there stated that they had no desire to have the rule prosecuted so far as the same related to the permission of their experts and engineers to examine the mines. The only question remaining for our disposition is whether or not an order should be made requiring the plaintiff company, being the appellant in said tax appeals. to produce its records, maps and other data for examination by the defendants prior to the trial. The cases of Happersett vs, Eaton, 20 D R 501; Graham vs. Cummings, 11 D.R. 68, are on all fours with the instant proceeding and the rule established by these cases and the authorities cited therein are controlling. The discussion in those cases are exhaustive, pertinent and illuminating to our present inquiry. Nothing could be gained by further elaboration thereon, and from the rule established therein we are of the opinion that we have no power to award the order as prayed for in said rule. And now, to wit, March 26, 1923, said rule is hereby discharged."

McNeil Coal Co. is Low Bidder on Coal For New Haven Railroad

The McNeil Coal Co., with offices at 342 Madison Avenue, New York City, was the lowest bidder for furnishing and delivering to the New York, New Haven & Hartford Railroad Co. 250,000 tons of bituminous coal for the eleven months period May 1, 1923, to April 1, 1924. The prices submitted by the company were $5.93 per gross ton on Fairmont coal and $6.04 on Kanawha coal for delivery alongside the railroad company's docks at Boston and Providence. The price at the mine is thus indicated at about $2.25 per net ton. The bids were not based on assigned cars.

Other bids reported were as follows: New England Coal & Coke Co., Kanawha, $6.95, and Fairmont, $6.49; C. H. Sprague & Son, Kanawha, $7.14; Steamship Fuel Co., Kanawha, $7.20; Consolidation Coal Co., Fairmont, $6.32, and Prudential Coal Co., Kanawha, $6.83.

The New Haven company will receive bids up to noon April 26 for furnishing and delivering approximately 17,000 tons of run of oven coke during the period May 1, 1923 to May 1, 1924.

National Guard Officers "Pass the Buck" For Not Stopping Herrin Massacre

Adjutant General Carlos Black, of the Illinois National Guard, blames Colonel Sam Hunter for the failure of the state to send troops to Herrin last June to stop the Herrin massacre. Colonel Sam Hunter blames Adjutant General Carlos Black. This official wrangle is going on before a special committee of the Illinois Legislature appointed to find out who is responsible for the inactivity of the state troops on those troubled days in June when a union mob besieged a non-union strip mine guarded by 26 hired armed men, accepted the surrender of 48 men and then brutally killed 22.

Colonel Hunter, who went to Herrin four days before the riot, has sworn that he repeatedly asked Adjutant General Black to send two companies of troops, even though Sheriff Melvin Thaxton declined to ask for them. He also declares that State's Attorney Delos Duty and County Judge D. T. Hartwell both refused to ask for troops, though he holds each had the authority. Duty is the man who has handled the two futile prosecutions of men indicted for murder at the massacre and Judge Hartwell heard both cases. Both juries acquitted the defendants and State's Attorney Duty said it was useless for the state to prosecute further and *nolle prossed* all the other murder indictments two weeks ago. Attorney General Edward J. Brundage went through the formality of filing a protest against dropping the cases.

Adjutant General Black has told the investigating committee that Colonel Hunter's testimony is "incorrect in some details." Most of these "details" are the vital ones in the matter. Colonel Hunter has been able, however, to present copies of telegrams and some other documentary evidence to substantiate his statements. He is slated for separation from the Nation Guard payroll on July 1 next. Adjutant General Black has been unable to explain to the committee why, if Colonel Hunter was so derelict in his duty last June, his discharge from the service was not arranged until recently, when it became evident that the Legislature was going to investigate.

Hoover Asks Aid of Trade Associations to Improve Efficiency of Railroads

In a letter addressed to approximately 3,500 trade associations Secretary Hoover asks for co-operation with the railway managers of the country in an effort to obtain the most efficient operation of the railroads. He points out that, due to the war and to the long-continued inability of the carriers to finance the necessary betterments, both productive capacity and consuming demands have now advanced beyond our transportation facilities.

The Secretary of Commerce goes on to state that while railway managers are making every effort in finance and expansion of facilities to meet the nation's necessities, full recovery of lost ground must be slow and he adds that if our present rate of productivity and employment is to be maintained it is vitally necessary that there be co-operation with the railway managements of both producing and consuming industries to assure the most efficient operation of the railroads. The principal direction in which such co-operation can be extended by the trades, according to Secretary Hoover, are: (1) Storage of their winter coal during the light-consuming season—that is, from now until Sept, 1, including the early movement of Lake traffic. (2) The loading of all cars to full capacity, and their prompt loading and discharge. (3) Reduction of reconsignment shipments and restriction of to-order bills of lading. (4) Demands for no more cars from the railways than can be promptly used.

"If we could secure the maximum efficiency in these directions," said the Secretary, "we will have added more effective commodity movement than would be brought about by the addition of 300,000 cars and 3,000 locomotives, and the addition of 10 per cent to our track mileage and terminal facilities.

"The importance of this lies in more than simply the maintenance of continuity of production and full supply of consumption because any strangulation in movement of commodities through car shortages affects the profits of every individual manufacturer by interruption in his production, and furthermore, such strangulation affects price levels in the most definite fashion.

"The full and smooth movement of all of the productivity of the country would be the greatest contribution that could be made at the present time in checking inflation or increase in price levels."

Railroads to Adopt Rating Plan in Illinois Whether Operators Agree or Not

The old order in rating Illinois coal mines for daily car allotment is changing. The principal coal-carrying railroads in that state, havng struggled for two months to get the operators to agree to their plan for rating mines by a railroad board, are on the point of putting the plan into effect. The operators tentatively accepted the plan but upon a condition which would require the Interstate Commerce Commission to render a decision on the assigned-car case after the new plan has had a 60-day trial. This is not acceptable to the roads.

States adjoining Illinois have already come to agreement with the roads. In western Kentucky the mine owners agree to abide by whatever rating the various roads put upon the mines provided they are not handicapped by whatever may take place on the same roads running across the river into southern Illinois. In Indiana the round-robin system of car distribution continues in effect with railroads fixing each mine's rating. The Big Four across southern Illinois has been working a round-robin plan for some time.

But in most of the fields of Illinois the old system, to which both the carriers and some of the mine owners object, remains in operation. A change may be expected at once. Under this old plan each mine gets its daily rating for each month based upon the average of each eight hours' production during the previous month, the operation reports to be made by the operator. There have been many abuses and a good deal of resultant discrimination as between districts.

Under the plan proposed by the road a railroad board will rate each mine arbitrarily, with mines under development getting special ratings, as now provided, and mine hours (not tipple time) will be the time basis. Reports are to be furnished monthly to the roads by the operators. If any operator persistently fails to do so, he can be penalized one-fourth of a week's allotment of cars. Joint mines will have to furnish the report to each road serving them.

The operators, through their traffic bureaus, by letter "tentatively accepted" the plan "with the understanding that the Interstate Commerce Commission will withhold its decision in case Docket No. 12530 in so far as that case applies to the rating of coal mines in the State of Illinois, and with the further understanding that if the operation of these rules during the first 60 days of the next car-shortage period does not result in an equitable distribution of coal-car equipment, as provided by the Act to Regulate Commerce and the decisions of the Interstate Commerce Commission, in the judgment of the operators, the Interstate Commerce Commission will render a decision immediately upon request of the Illinois operators on the evidence already submitted . . . and prescribe just and reasonable rules for rating coal mines." Docket 12530 is the now famous assigned-car case.

The position of most Illinois carriers is that they cannot make any agreement that binds the Interstate Commerce Commission or anybody else. Therefore it is expected the Illinois Central, the Burlington, C. & E. I. and one or two other of the principal coal carriers will put their rating plan into effect at once without any signed agreement.

FIELD INVESTIGATIONS into the question of community storage, studies in which subject are being made by F. R. Wadleigh, Federal Fuel Distributor, have been completed in Minneapolis and St. Paul, Mr. Wadleigh announced April 13. Similar field investigations are being made by E. A. Blake, G. S. Pope and G. J. Pride, in Chicago, Detroit, Buffalo, Worcester, Indianapolis and Cleveland.

Coal Commission Seeks Means to Curb Royalty Demands of Owners of Anthracite Lands

By Paul Wooton
Washington Correspondent of *Coal Age*

How under the laws of Pennsylvania, or by interference on the part of the federal government, can a curb be placed on the royalties demanded by those holding anthracite lands? This is a question which is uppermost in the minds of the members of the President's Coal Commission, now that they are concentrating much of their attention on the anthracite industry. Governor Marshall declared on Saturday that he would like very much to hear from anyone who has a sound idea as to how the land owners can be prevented from charging royalties which "they jolly well please." At that point Chairman Hammond interposed to say that he would put it stronger and say "what they damn please." It was stated at the Saturday conference that this question of meeting the royalty situation will be put to Senator Pepper and to every other person appearing before the commission who is likely to have an opinion on the subject.

All of the members of the commission, with the exception of Governor Marshall, will spend most of this week in the anthracite region. The commission will be accompanied by D. C. Ashmead and another of its anthracite specialists. Mr. Ashmead recently resigned from the editorial staff of *Coal Age* to engage in field work for the commission.

Much Evidence at Public Hearings Irrelevant

During the Saturday conference Governor Marshall went into detail in explaining why the commission will limit its public hearings. He stated that during the eight years that he was president of the Senate it was his observation that 75 per cent of the so-called evidence taken during public hearings was not pertinent and that the public money expended to print it was wasted. There will be public hearings, he said, but only on matters concerning which agreement as to the facts cannot be reached in any other manner.

He pointed out that the assembly of the contending parties to a controversy, each supported by smart lawyers, and where the main purpose is to put the other side in a hole, is not likely to bring out the real facts from which conclusions may be drawn. Governor Marshall said that he was disgusted with the way the testimony before the Kenyon committee was jumbled up by the lawyers. In such public hearings as the Coal Commission conducts, he stated, the text will be the exact fact in controversy and witnesses will be required to confine their remarks to that text. Moreover, he declared that the public hearings will be conducted along the lines of a lawsuit. No one will be heard until sworn.

The receipt of a 25-page letter from a woman residing at Herrin, Ill., appealing to the commission for relief on the ground that her husband had been discharged from his position because he served on the grand jury that considered the case against the rioters was cited by Governor Marshall as being typical of a general misconception that has grown out of the request of the commission for information as to breaches of civil rights of American citizens.

"The purpose of the commission in calling for information on the subject," said Governor Marshall, "is to get the evidence of these violations of law so that the principle can be stated and so that a determination can be reached as to whether or not the principle has been violated. Many unwittingly have conceived the idea that the commission is an organization which can assume the rôle of prosecuting attorney, grand jury, petit jury and sheriff, as the case may be, and that it has the authority to prosecute criminal causes and assist in the bringing of civil actions for damages.

"These are not functions of the commission. The courts are the places to prosecute criminal cases and claims for damages. The scope of the commission's work is limited to the ascertaining of the facts as to what are the civil rights of an American citizen, the breaches that have taken place, and to recommend legislation, if that be necessary, or other methods looking to a cure. The commission cannot bring prosecutions or furnish attorneys. All it can do is to make an honest endeavor to get the truth."

The fact that the act gives an immunity bath to those who testify before the commission is regarded by Governor Marshall as being helpful in that he believes that persons appearing before the commission are more likely to be entirely frank when there is no fear of being indicted for what they say.

The commission is face to face with the question as to whether unlimited and uncontrolled competition will result in cheaper coal to the consumer, Governor Marshall said, or whether that end can be attained better if controlled combinations are allowed. Conclusions, however, must await the time when all the facts are in, he asserted. In so far as anthracite is concerned, Governor Marshall said that he is "not certain that any cheaper coal has become available because of any dissolutions that have taken place." For thirty years, he said, there has been constant litigation between the United States and the railroads and mines in the anthracite region.

In Governor Marshall's opinion, the Hepburn Act now meets the full approval of the U. S. Supreme Court. The commission is interested, he said, in having coal furnished the consumer as cheaply as is consistent with fair returns to owners and legitimate investors; with wages to the men who do the actual work commensurate with the American idea of living conditions, and with reasonable freight rates. The commission wants to ascertain by what plan greatest economy can be effected in the mining, the transportation and the distribution of coal and which will insure to the consumer the proportionate part of those economies to which he is entitled. To these aims was added that of assuring an adequate supply of coal to meet the needs of the country.

To Study Mining Methods and Engineering Problems

The commission has advanced far enough with its compilation of facts as to the earnings of the anthracite producers to lead its members to believe that more absolute information in that particular will be available than has been compiled in any other industry. Those members of the commission who will visit the anthracite field will start their inspection visit at Scranton and will proceed through the Wyoming, Lehigh and Schuylkill districts. Mining methods and engineering problems will be studied particularly.

Chairman Hammond announced Saturday that the commission has received about twenty per cent of the 2,400 schedules covering wage rates that had gone out a month previous. Detailed reports on earnings covering 200,000 employees have been received. Early in the week beginning April 9 the commission's staff numbered 410. This is believed to have been the maximum number that it will be necessary to employ. On Saturday the total had fallen to 402, and it is believed there will be a gradual decrease in personnel from this time forward.

The specialists of the Public Health Service now are engaged in the Logan County and the Kanawha fields. The causes of strikes are being studied by a field force of fourteen men, who are making daily reports that are being analyzed at the commission's offices as they are received.

The schedules covering wholesaling and retailing of coal are practically complete and will be mailed out soon.

Prof. J. H. Hollander, of Johns Hopkins University, has been retained by the commission to make a special study of investments, profits and corporate control in the anthracite industry. Professor Hollander is an economist who has had wide experience in financial matters. As Treasurer of

Porto Rico, he organized the Treasury Department of the island and introduced its present revenue system. He was special commissioner to Santa Domingo in 1905 and was largely instrumental in readjusting its public debt.

Among those appearing before the commission last week were General Goethals and W. Thorneycroft. General Goethals pointed out the inefficiency of existing law in the handling of the coal situation in time of emergency. He urged the enactment of a law with teeth, which could be invoked if the situation should require it. In his opinion, the situation should be handled by an administrator who would have wide powers that would supersede those of any other government agency.

Mr. Thorneycroft conducts extensive coal operations in Great Britain. He informed the commission as to the practical working out of the profit-sharing arrangement now in force in the British Isles.

The Bureau of Mines has advised the Coal Commission that it will furnish it with a digest of certain state legislation affecting coal.

Grand Jury Indicts 32 in Connection With Armed March in Logan

Harold W. Houston, of Charleston, chief counsel of the United Mine Workers of District 17, and thirty-one others were indicted by a grand jury in Logan County on April 13, charged with being implicated in the armed march against Logan. Houston is specifically charged with being an accessory before the fact in the death of John Gore and three other deputies of Logan County during the march. No indictment was returned against C. F. Keeney, president of District 17, although there had been rumors that the grand jury might be asked to reindict him.

When the true bill was returned against Houston, who has had a leading part in the defense of others alleged to have been connected with the armed march, he was absent from the city preparing for the trials which were set to be called at Charles Town on April 16. Houston's name had frequently been mentioned in connection with testimony given at previous trials growing out of the trouble on the Logan border. It was stated on April 14 by T. C. Townsend, of Charleston, associated with Houston in the trial of the miners, that the chief counsel of the mine workers would voluntarily surrender upon his return to Charleston.

Among the others indicted were Elmer Blankenship, against whom indictments are already pending; G. C. Hickey, recently released on bail by the West Virginia Supreme Court; Henry Wright, Bert Castle, U. S. Cantley, J. E. Miller, Ed Kay, Anthony Ness, S. S. McDaniels, Anderson Fauber, William Danaway, A. C. McCormick, George Garrison, Frank Adkins, Walter Regner, Ralph Legg, Will Singleton, George Mathell, a man named Childreen and another man named Irons.

Failure of the jury to reindict Keeney and Fred Mooney district secretary of the union, does not mean that charges against them will be dropped, according to Prosecutor John Chafin. Keeney, he said, will be tried later under an old indictment charging him with being accessory to murder.

Strike Wanes in Kanawha Field

Although about 2,000 coal miners in the Kanawha field struck April 1, before the end of the week the number of miners on strike had been reduced to 825 in all as additional companies entered into a contract with the miners' union for the new coal year. Contracts had been signed covering about 70 mines, the new agreements being between individual mining companies and the United Mine Workers rather than between the miners' union and the Kanawha Operators Association as a whole, as some of the companies which signed the Cleveland pact withdrew from the association after becoming parties to the union agreement.

Approximately 50 coal companies, producing about 30 per cent of the tonnage in field, have signed the new agreement. The remaining companies in the field have not signed with the union and have indicated that they will not do so.

New York Mayor Submits Eight Queries to Dealers in Coal Investigation

Wholesale and retail coal dealers in New York City have received from John F. Hylan, Mayor, a questionnaire relating to their business, which they are requested to fill out and return to the Mayor's office not later than April 23.

The replies are to be used by the Mayor in his investigation of the Coal situation which he proposes to make in an effort to avoid a recurrence of last winter's shortage of fuel. Some replies, it was said, have already been received, but nothing could be learned as to what they disclosed.

The questionnaire contains eight queries, as follows:

How many tons of anthracite did you sell in New York City between April 1, 1922, and April 1, 1923?

How many tons of bituminous coal did you sell in New York City between April 1, 1922, and April 1, 1923?

What was the range of sales prices per ton between April 1 and Sept. 1, 1922, on anthracite and on bituminous coal?

Between Sept. 1, 1922 and April 1, 1923, on anthracite and on bituminous coal?

What proportion of anthracite did you sell directly to householders and what proportion to dealers?

What proportion of bituminous coal did you sell to householders (apartment houses, private houses, etc.), and what proportion for commercial use (factories, etc.)?

How many tons of anthracite did you sell in New York City during the twelve months previous?

How many tons of bituminous coal did you sell in New York City during the twelve months previous?

Between what range of prices?

Another questionnaire, for large users of coal, also was sent out, in which they were asked how many tons of anthracite and bituminous coal they used, the prices paid, by whom supplied, what proportion of hard and soft coal was used in previous years, the effect of the use of soft coal on boilers, on property and on the neighborhood, and what the user is doing to insure an adequate supply of hard coal during the ensuing twelve months.

Mayor Hylan asks that the answers to this questionnaire be mailed to him before April 30.

Having Licked All Comers Jack Dempsey, Now Will Try Running Utah Coal Mine

"If there is one thing I know more about than fighting, it's how to mine coal" are the words with which Jack Dempsey, heavyweight prizefighter of the world, astonished the world April 10. Whereupon it was officially announced at a meeting in Salt Lake City of directors of the Great Western Coal Mines Co., that William H. Dempsey (that's the rock crusher's home-grown name) had been elected president of the company and that John L. Kearns, the champion's manager, is now secretary and treasurer. Dempsey and Kearns have invested an unannounced amount of their cash in the company and will begin within six months to mine coal from their 2,000-acre tract in Carbon County, Utah. They also say they have taken over 6,000 acres of agricultural land in Castle valley, near by. A new townsite called Dempsey City is to be laid out and possibly populated. Dempsey said "If I ever fight again, that's where I'll train."

Class 1 Railroads Consume 10,358,000 Tons Of Coal in January at $3.75 per Ton

Class 1 railroads consumed 10,358,000 net tons of coal during January, 1923, as charged to account 394, compared with 10,127,000 tons in December and 8,121,000 tons in January, 1922, according to a recent report of the Bureau of Statistics of the Interstate Commerce Commission covering 176 steam roads. The delivered cost per ton in January last was $3.75 compared with $3.60 for the corresponding month of last year.

Consumption of fuel oil in January totaled 150,317,000 gallons, compared with 157,380,000 gallons in December and 126,796,000 gallons in January a year ago.

N. C. A. Directors and Smokeless Operators Pledge Aid To Coal Commission; Labor Evils Outlined

That the U. S. Coal Commission will be given all possible assistance in its work by the bituminous coal operators was assured by the directors of the National Coal Association and by the Smokeless Coal Operators' Association of West Virginia at meetings in New York City on April 11 and 12.

Both bodies received the report of the April 10 meeting of the Bituminous Operators' Special Committee, of which John C. Brydon, of Somerset, Pa., is chairman. The report outlined four major obstacles to satisfactory bituminous-coal mining from the standpoint of the public and the industry and for which solutions will be recommended to the Coal Commission. These evils, the report says, are:

"(1) Instability of labor conditions, due to the monopolistic power and methods of the United Mine Workers of America, with the following consequent handicaps to the industry:

"(a) Inability of mine owners to lay plans even a year ahead with any certainty of regular operation.

"(b) Inability on the part of the industry to make maximum use through steady shipments of the transportation facilities of the country.

"(c) High costs of mining, resulting in high prices, due to constantly interrupted and therefore uneconomic operations and to property losses through violence.

"(d) Exorbitant labor costs, causing prices which force other working people in effect to exchange from two to four days' labor for one day of mining labor when they buy coal.

"(e) Continual threats of even higher wage demands, to be enforced by bludgeoning and violence.

"(2) Transportation difficulties. These constitute an obvious and fundamental deterrent to satisfactory supply and price of coal. Problems of car shortage and suggestions for improving the present system of car distribution are being studied.

"(3) Seasonal demand. A determined and thorough effort by the industry to encourage and teach the storage of coal is certain to be one of the committee's recommendations.

"(4) Speculation. Out of the evils listed above grows destructive opportunity for the industry's barnacles, the speculators who, and those mines which, lie idle when supply is normal and strive for 'killings' when demand is hot and prices high. The great body of constructive business citizens who constitute the bulk of the bituminous mining industry are as desirous as the public itself to so stabilize the industry as to stamp out the speculator."

The report was discussed at length by the directors of the National Coal Association on April 11, at the conclusion of which Alfred M. Ogle, president of the association, said that it was necessary that the misunderstandings existing between the public and operators be gotten rid of. He said it was intended to start an educational campaign with that idea in view and that the special committee of which Mr. Brydon is chairman would have offices in Washington, from which place statements would be issued from time to time.

The Smokeless Operators' Association of West Virginia at a meeting held the next day also received the report of the special committee of operators and pledged its assistance to the Coal Commission. At the luncheon following the meeting Harry L. Gandy, the recently selected executive secretary of the National Coal Association, spoke briefly asking the co-operation of the members of the association in his work.

To assist Mr. Brydon's committee in its work of obtaining information needed, the following were appointed:

D. C. Botting, of Washington; Moroni Heiner, Utah; W. F. Megeath, Montana; P. J. Quealy, Wyoming; G. F. Bartlett, Colorado; J. G. Puterbaugh, Ira Clemens and W. L. A. Johnson, Southwest; E. C. Smith, Iowa; George B. Harrington and F. C. Honnold, Illinois; P. H. Penna, David Ingle, M. L. Gould and J. B. Pauley, Indiana; George H. Barker, W. D. McKinney, D. F. Hurd and S. H. Robbins, Ohio; S. Pemberton Hutchinson, Julian B. Huff and W. M. Henderson, western Pennsylvania; B. M. Clark and G. Dawson Coleman, central Pennsylvania; C. E. Reed, C. F. Richardson, Frank D. Rash, John Price and E. L. Douglass, Kentucky; R. E. Howe, E. C. Mahan, E. R. Clayton and Alex. Bonnyman, Tennessee; S. L. Yerkes, Alabama; E. E. White, R. H. Gross, C. C. Dickinson, Frank Lyon and Oscar Deyerle, West Virginia; C. E. Bockus, Virginia, and J. S. Brophy, Maryland.

U. S. Chamber of Commerce to Discuss Coal Problem at Annual Meeting

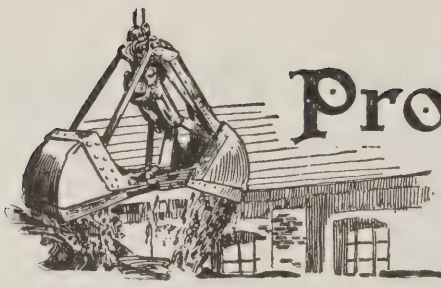
The coal problem will take up the entire session of the Natural Resources Production group at the eleventh annual meeting of the Chamber of Commerce of the United States in New York, May 7-11. Details of the group meeting program, announced by W. DuB. Brookings, manager of the Natural Resources Production Department of the National Chamber, indicate that three aspects of the coal situation will be covered in the addresses scheduled to precede the general discussions. The program follows:

"Some Problems of Coal Distribution," by J. D. A. Morrow, president, Morrow Callahan Coal Co.

"Labor and Its Relation to the Cost of Industrial Coal," by J. G. Bradley, president, Elk River Coal & Lumber Co.

"Economic vs. Legislative Solution of the Coal Problem," by George H. Cushing.

"Distribution is one of the most important elements in the entire coal problem," Mr. Brookings said in making the announcement. Mr. Morrow is admirably fitted to speak on this subject. During several years of active management of the affairs of the National Coal Association, he became familiar with the problems of distribution from the point of view of the operator. During the war and afterward he rendered valuable assistance to government officials in charge of the distribution of the nation's fuel."



"The second subject to be presented for discussion, that of 'Labor and Its Relation to the Cost of Industrial Coal,' is obviously of vital interest to the manufacturer. As an operator for many years in the non-union fields and as past president of the National Coal Association, Mr. Bradley has a background which well qualifies him to handle this subject."

"The third subject, 'Economic vs. Legislative Solution of the Coal Problem,' presents an opportunity for the broadest sort of discussion. Mr. Cushing has been a student of coal for many years and is conceded to be one of the best speakers among coal men and one of the most original thinkers on the coal problem."

Coal-Investigation Bill Presented in New York Legislature

Albany, N. Y., April 16.—A bill creating a commission to investigate the production, transportation, distribution and prices of coal, and making an appropriation of $25,000 therefor, was introduced in the New York Legislature today by Assemblyman W. W. Campbell, of Schenectady.

The measure provides that the commission "shall investigate the quantity and kind of coal presently available and to be available in the future for the use of the people and industries of this state, the estimated amount of coal, of the several sizes and kinds, to be required for such use, and all matters and transactions affecting the production, transportation and distribution of coal for use in this state and tending to inflate the prices thereof, together with ways and means to prevent shortage of coal and excessive prices, to the end that the state, by remedial legislation, recommendations to Congress and otherwise, may take such measures that hereafter there may be a permanent and adequate supply of coal equitably distributed at reasonable prices."

Production and the Market

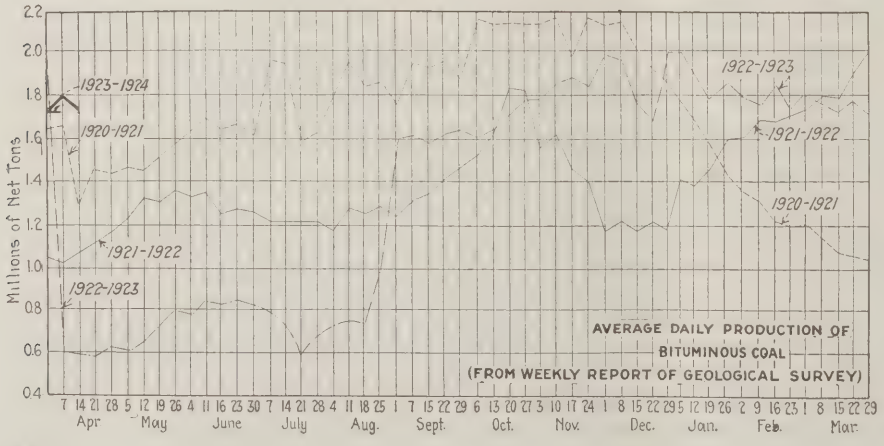
Weekly Review

Despite the general dullness of the soft-coal market, April so far has been exceptional in the steadiness of price and the quantity of output. Production continues at the rate of 10,500,000 tons per week, even though stocks at the end of the coal year were high for an off-strike year. Some indication of where the coal is going is found in the figures of coal used in coke manufacturing. In March nearly 7,500,000 tons of soft coal were used in the production of coke, both beehive and byproduct, as compared with an average per month in 1922 of 4,500,000 tons of coal. Railroads are consuming some 500,000 tons of coal per week more than a year ago and public utilities are consuming over 3,500,000 tons per month—some 500,000 tons more than in early 1922. Thus the largest users—the railroads, the iron and steel industry and public utilities—are taking more than half the current output of soft coal. There is no excitement in the trade, for this coal is moving forward quietly on current orders and more and more is being tied up on contracts. Kanawha and Fairmont coals have been offered without assigned cars on a basis of about $2.25 per net ton at the mines on railroad contract business.

Price Index Registers Slight Increase

The general status of the soft-coal market remained about the same as last week. *Coal Age* Index on Monday, April 16, was 235, as compared with 233 the previous week, the corresponding average price being $2.84. Price increases in Pocahontas, western Kentucky, eastern Ohio, Pittsburgh and Clearfield sections were offset by declines in southern Illinois, eastern Kentucky, Hocking, Cambria and Somerset.

Production for the week ended April 14 is estimated at 10,500,000 tons. Cumulative production in the calendar year to April 7 was 148,867,000 net tons, an increase of 15,744,000 tons over 1922 and 39,579,000 tons over 1921.



Lack of cars continues to be the principal factor limiting production in many fields, notably in the East. Since the first of the month the roads have ceased to give coal the preference in movement afforded during the winter. Total freight movement is at a record level and the share that is going to coal is decreasing. In the West the lack of market has long since been of more importance than cars. In the Middle West hope for summer operation is being pinned to a good market in the Northwest and among retail dealers. Down East and in the South the record rate of industrial activity is taxing railroads and using coal as fast as it is produced.

Little Export Business Being Closed

Export demand for coal continues quiet. There are some inquiries for July delivery, but little if any business is being closed. Italian gas companies last week asked for bids on upward of 30,000 tons of Youghiogheny or Westmoreland gas coal in competition with British coals. Some shipments on regular business were reported as having been made for South American railroads. Demand for coke was easier, one cargo being reported as having been sold for shipment to Belgium. Dumpings at Hampton Roads during the week ended April 12 were 393,848 net tons, as compared with 400,267 tons the previous week.

Buyers are puzzled over the outlook in New England. Production is ample, but rail transportation is causing apprehension. Rail routes are congested and embargoes were in force last week against the New Haven and the Boston & Maine railroads.

The closing of mines in union districts on Eight-Hour Day, April 2, reduced production on that day to about 42 per cent of the average of recent Mondays. The estimated total of coal raised during the week April 2-7 is 9,725,000 net tons, and the indicated daily average output for the week of 5.42 days is 1,794,000

Estimates of Production

(Net Tons)

	1922	1923
BITUMINOUS		
March 24	11,448,000	10,424,000
March 31 (*b*)	10,469,000	10,430,000
April 7 (*a*)	3,835,000	9,725,000
Daily average	639,000	1,794,000
Calendar year	133,123,000	148,867,000
Daily av. cal. year	1,613,000	1,800,000
ANTHRACITE		
March 24	2,095,000	2,126,000
March 31	1,896,000	2,008,000
April 7	9,060	1,602,000
Calendar year	21,786,000	27,470,000
COKE		
March 31 (*b*)	191,000	388,000
April 7 (*a*)	175,000	427,000
Calendar year	1,983,000	5,137,000

(*a*) Subject to revision. (*b*) Revised from last report.

tons. The present week, April 9-14, opened with 38,188 cars loaded on Monday and on each of the next three days loadings were between 30,000 and 31,000 cars. The total output for the week probably will be about 10,500,000 net tons, says the Geological Survey.

Anthracite domestic sizes continue to move in good volume but not sufficiently to enable retail dealers to take care of their customers' orders. The steam sizes are dragging and some producers have found it necessary to offer inducements to keep them moving.

Midwest Conditions Unsatisfactory

Throughout the Midwestern region some domestic coal is still selling, due to chilly weather and also because of the transportation difficulties in getting Pocahontas and other Eastern domestics into Indiana and Illinois. Household trade in coal for next winter has not begun though retailers say there is more interest in "buy now" than there normally it at this time of year.

The middle sizes of Indiana and Illinois coal are dragging badly and choking up the lines with unbilled cars. On its Illinois lines alone the Burlington road during the week carried approximately 1,000 cars a day of no-bills. Most mines in those two states which depend to any extent upon spot market worked two days and numbers of them were shut down for the time being.

In southern Illinois several mines have been idle on account of a strike of the line men with the principal power company. Some mines in the Mt. Olive field have worked but two or three days during the last month. Equipment furnished is hopper-bottom that the country dealer cannot unload, and added to that the price is high, so that business in that field is almost at a standstill. In the Standard field there is little change from last week. The demand is not quite so good and railroad tonnage has fallen off. Car supply has been a little short at some points, but seems to be ample for the demand.

St. Louis Business Is Slow

Warmer weather eased up the domestic demand in the St. Louis market. Deliveries of anthracite became good during the week for the usual spring storage, but it is earlier this year than ordinarily. Wagonload steam has been good, but carload is slow.

Country domestic trade is almost at a standstill and country steam has not responded for the past two or three

*Net tons, f.o.b. mines †Advances over previous week shown in **heavy type,** declines in *italics.*

Coal Age Index 235, Week of April 16, 1923. Average spot price for same period $2.84. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

weeks. Indications are that there will be a light tonnage of anthracite available of this territory and gas-house and byproduct coke are reported as sold up until June 1.

Louisville Dealers Do Not Stock

Lake movement is slow in development, due to ice, late opening and the fact that the Lake buyers are opposed to paying prices as now quoted. While industrial demand is fair and some retailer demand in sight, the retailers are slow in stocking, as there is practically nothing to warrant an advance in the markets for some weeks to come.

Railroad consumption is heavy and the manufacturers of building supplies are operating at capacity.

Northwest Trade Is Quiet

Shipments from the Duluth docks fell off in March, only 10,826 cars going out. This compares with 13,966 cars in February and 21,249 cars in March last year. The falling off is opportune, as there are only about 700,000 tons of coal on the docks now, of which not more than 300,000 is free. Youghiogheny and Hocking lump were gone entirely as are also Pocahontas lump and mine-run. There is some Pocahontas screenings and a large amount of bituminous screenings left.

Mild weather for a few days lulled the Milwaukee coal market almost to sleep. The dock yards are well cleaned up, but enough coal is coming by rail and carferry to supply all demands. Jobbers are looking forward to a season of keen competition when navigation opens, because operators want to force an early movement of coal.

As Western Markets Sag, Prices Fluctuate

With an almost complete end to the demand for domestic sizes, mines through Kansas, Arkansas, Missouri and Oklahoma are closing rapidly. Few mines are open in Arkansas. Naturally, with such conditions, there is considerable price slashing.

In Colorado the dollar-off spring storage prices are beginning to move both lignite and bituminous to dealers' yards. Bituminous moves at $5 for lump and $4.50 for nut. This is 50c. under the price at this time last year. Good lignite lump goes at $3. Even these comparatively low prices are being undercut $1 in Denver by a little bituminous from Hanna, Wyo.

In Utah the market is soft indeed for everything produced and several mines have shut down. The average working time for the state during the week was 30 per cent. Prices fluctuate wildly.

Smokeless Features Cincinnati Market

The one bright spot in the Cincinnati market is the smokeless coal situation, advances having been scored during the past week on the prepared coals, due to the fact that most of the Pocahontas producers have all the business they can handle. The Lake situation has not cleared up to any appreciable degree, each rumor of sales casting a different complexion on the situation. The premiums that had been asked for byproduct coal have been pretty well wiped out in so far as spot coal is concerned. Nor does there appear to be much inquiry for future supplies or any deals on a contract basis. Rejections were reported as numerous, throwing more coal on the open market.

The chief feature of the Columbus market was weakness in all grades, but more principally in mine-run and prepared sizes. Buying was restricted largely to current needs. Contracting for steam tonnage attracted some attention, but many users have not yet closed up. In the meantime they are using up reserves which were accumulated in the past few months. Business is expected to be dull until the Lake season gets in full swing, which may be much later than was generally expected. A considerable Lake tonnage has been contracted for and prices are said to be generally good.

Surplus Fuel Disappears in Eastern Ohio

During the past week the surplus fuel around Eastern Ohio markets disappeared and there was little or no distress coal about. Demand picked up somewhat and inquiries were received on contract requirements. Contracting has not yet assumed any appreciable proportions because of price differences, and the closing of many contracts is being deferred awaiting stabilization of market conditions. During the week ended April 9 the lower Lake ports dumped 125,000 tons of cargo coal and in addition to this the boats took 10,000 tons of fuel.

In northern West Virginia the railroads have not been offering more than $2 to $2.25 for railroad fuel contracts and many operators have declined to sign at that figure owing to the fact that the Lake season should open soon, and then better prices may be obtained. Tidewater shipments are not so large and coal is being retarded in transit as a result of congestion at Curtis Bay and other piers. Some of the larger companies have their coke output sold up for April and May.

Pittsburgh Steam-Coal Mines Close

In the Pittsburgh district additional steam coal mines are closing, following the closing in the past few weeks of a number of mines in the Connellsville region. Practically no steam-coal contracts have been made for the coal year and only a few gas-coal contracts, but there are regular understandings whereby shipments are made and the price is adjusted at intervals.

There was no improvement noted in the Buffalo situation, though it was reported that there was not so much coal on track as a short while back.

Outlook Puzzles New England Buyers

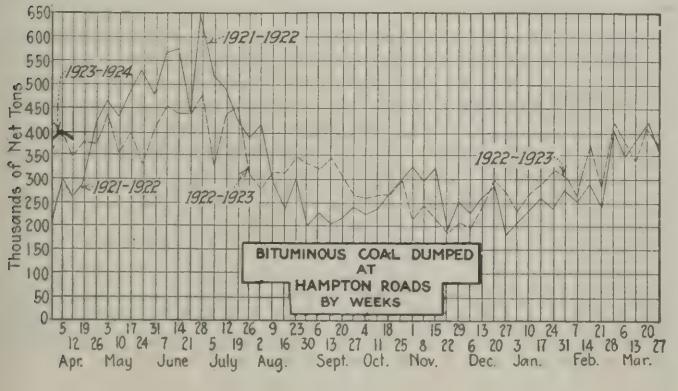
Buyers in New England are puzzled over the outlook. The rail routes into New England are now heavily congested, available motive power considered, and the first half of April will doubtless show a material drop in receipts at the Hudson River gateways. Embargoes are now in effect against both the New Haven and the Boston & Maine, leaving the Boston & Albany the only line open at this writing.

A few stray cargoes of British coal were still being received for locomotive use, but the trade understands that this source of supply has now diminished to a point where it is practically negligible. There was still congestion at Boston and at Providence, especially at railroad berths, but fewer arrivals probably will be the means of clearing up this particular situation.

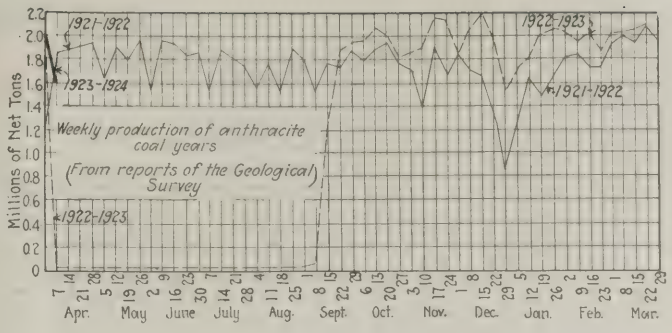
There continue to be ample supplies of navy acceptable coal on wheels at the Virginia terminals. Dispatch is excellent, but the spot market suffers from inadequate buying. Prices have not receded quite as expected, but most interests feel the trend is lower.

All-rail territory is being closely canvassed for spot business. Only a small proportion of mines in the central Pennsylvania districts have business ahead and quotations continues to sag. A few high-grade coals are still commanding a range of $3.50@$3.75 per net ton, but even these mines have few orders in hand and are being operated only from week to week.

Better Feeling Pervades New York Market



There was a better feeling in the New York market. Inquiries were more frequent, but actual buying was slow. Consumers are more particular as to the quality of coal purchased. The Philadelphia market was extremely draggy. There are no signs of heavy stocks around industrial plants and no amount of urging would induce consumers to take in coal. Some producers look for a decided change for the better about June 1.



The demand at Baltimore was not heavy and contracts have not been closed in such volume as was hoped for.

The steam trade at Birmingham, Ala., remained quiet. Domestic sizes were in good demand, as the principal producers are pretty well sold up and there is ample spot business offered to take the tonnage above contracts on hand. Production for the week ended March 31 reached 416,000 tons, as reported to the Alabama Mining Institute. The output for the quarter ending with March was 5,017,000 tons.

Demand for Anthracite Continues Strong

Producers have no difficulty in moving their anthracite domestic coals. Demand continues strong and retail dealers could handle larger tonnages. Consumers are anxious to fill their bins for next winter. In the New York market the steam sizes are causing a little trouble, but so far not sufficient to make it necessary to send them to the storage yards. In Philadelphia the most wanted size is chestnut. The Baltimore situation is comparatively easy. During last week more than 250 cars were reported as

received. Consumers are being urged to lay in their next winter's coal.

"The observance of Eight Hour Day—April 2—as a holiday at the anthracite mines," says the Geological Survey, "was responsible for complete suspension of work, and production declined sharply in the week ended April 7. Using as a basis the 30,637 cars reported as being shipped by the anthracite carriers, the total output was estimated at 1,602,000 net tons, a decrease of 20 per cent over the week preceding. This suspension on Monday was not responsible, however, for the entire loss, as shipments did not reach normal until Thursday. The corresponding week in 1922 witnessed the outbreak of the miners' strike and production was but 9,000 tons.

"The cumulative output during 1923 to date now stands at 27,470,000 net tons, an increase over the corresponding period of 1922 of 5,684,000 tons, or 26 per cent."

Coke Production Rebounds

The production of beehive coke during the week ended April 7, says the Geological Survey report, showed a gain of 39,000 net tons over the preceding week, or 427,000 tons as compared with 388,000 tons the previous week. The increase was principally in Pennsylvania and small gains also were shown in the Southern Appalachian region.

Foreign Market And Export News

Holiday Reduces British Coal Production; Canada Enters Market

There were 4,874,000 tons of coal produced in Great Britain's mines during the week of March 31, according to a cable to *Coal Age*. The week included Good Friday with in most cases a holiday on the succeeding day, leaving virtually four working days in the week. The previous week's production was 5,703,000 tons.

The Welsh market is exceptionally busy satisfying Continental demand, and for the next two months the mines have heavy orders ahead. The main directions of export continue to be France and Italy, especially the latter, where the current rate of export is creating a record. During the past few days Canada has been asking for substantial quantities of Welsh coal.

Most of the north English mines are booked up until the end of June. Owing to political events in Germany, Belgium, France and Germany are showing less keenness to buy. The German State Railways inquired for 50,000 tons of Northumberland and Durham coal for shipment in April and May.

Coal exports officially reported from London for the weeks ended April 6 and April 13, were, in tons:

	April 6	April 13
South Wales District	32,485	.....
Newcastle (Tyne) district	3,783	1,140
Mersey	6,784	.....
Clyde	.....	4,700

Slight Dullness at Hampton Roads

Reduction in export business, with a slight slump in bunkers, caused dullness in the Hampton Roads market last week. Stocks continued to pile up at the piers, with a consequent drop in prices. The slump was regarded by the trade, however, as temporary.

Shipments to France continued on a small scale, indicating better business of this character later. Some bunker business was obtained for transatlantic vessels which put in here en route from New York, because of the coal handlers' strike there.

Coastwise trade was holding up fairly well. In the domestic trade preparations were being made for the advent of warm weather and the natural decline in business. The tone of the market was only moderately strong.

Denmark's 1922 Fuel Importations

There were imported into Denmark during 1922, according to a report received by the Department of Commerce at Washington from Chargé d'Affaires P. L. Cable, 2,839,000 tons of anthracite and briquets as compared with 2,093,000 tons in 1921, and 794,000 tons of coke and cinders, as compared with 469,000 tons in the previous year.

Practically all of the coal imported in 1922 came from Great Britain; Germany supplied about 12,600 tons of anthracite, and the United States 121 tons. In addition to the coal and coke imports there were received into the country 76,000 tons of illuminating paraffin, 52,000 tons of petrol and 75,000 tons of other non-dutiable fuel oil.

News Items From Field and Trade

ALABAMA

A temporary order was granted April 7 by Judge William I. Grubb, in the U. S. District Court at Birmingham **restraining the United Mine Workers from interfering by picketing or otherwise with the operation of the Beltona mine of the American Fuel Co.**, which alleged in petition to the court that it is engaged in supplying coal for trains operating in interstate traffic. The bill of complaint set forth that pickets "by force, threats of violence, jeers and other offensive conduct" prevented miners continuing in employment or accepting employment by the coal company and that such action had lessened the output of the mine to such an extent that its contracts with the Louisville & Nashville R.R. had been seriously interfered with. The order is directed against the national organization, district No. 20, and its officers, Beltona local and its officers and several individuals, including two district organizers. No date has been fixed for a hearing in the matter. The order is effective for ten days. Three hundred union miners employed at the mine have been on strike three weeks.

Deals are pending involving a consideration of $13,000,000 or more whereby developed and undeveloped coal properties in the Birmingham district will change hands if consummated. New York and Pittsburgh interests are said to be negotiating for the purchase of extensive mining interests, including a large acreage of undeveloped lands in Walker and other counties controlled by L. B. Musgrove and associates, the consideration reported as being around $3,000,000. Other interests are negotiating for the purchase of plants and equipment and coal tracts of two of the larger independent commercial companies, which it is stated will involve a consideration around $10,000,000. If the deals go through, the new owners contemplate extensive improvements and enlargements, including possibly byproduct coke ovens. Definite information is yet unavailable but deals are reported progressing satisfactorily.

CONNECTICUT

Bridgeport retail dealers have announced **a cut of $1 per ton in the prices of domestic sizes of anthracite.** They will sell for $15,50 per ton with pea coal at $14.

ILLINOIS

The Egyptian Coal & Mining Co., with two large mines at Marissa, capable of producing 2,500 tons daily are now sales agents for the entire output of the Nashville Mining Co. mine at Nashville. The maximum output for this mine is 1,000 tons a day.

Arthur Ratcliffe is drilling for No. 1 vein coal five miles west of Geneseo, with the idea of opening a wagon mine, on a cement highway connecting Geneseo and Moline.

Loss of approximately $6,000 was sustained by the Black Star Coal Co. recently when a group of houses belonging to the company was totally destroyed by fire. Miners in the employ of the company were living in the houses at the time and the loss is said to have been only partly covered by insurance.

The O'Gara Coal Co. has called a special meeting of stockholders to be held April 28 to vote on the plan **to increase the capital stock** from $6,000,000 to $16,000,000.

Articles of incorporation have been issued to the **West Side Coal Co.**, of Danville. Capital stock is listed at $25,000 and the incorporators are Al. L. Delvalley, A. J. Delvalley and Joseph F. Skelton. The company will engage in the mining of coal, fireclay, ores, metals and minerals.

Recent reports on the **Kathleen mine**, at Dowell, controlled by the Union Colliery Co., of St. Louis and Chicago, indicate that the mine **is being developed at a rapid pace.** The output of the plant has increased steadily until it now averages in the neighborhood of 4,000 tons daily. The company recently completed a 500-ft. drive through a solid rock fault and is now running entries on the other side of the fault. The output of the mine is expected to reach 8,000 tons some day.

The Illinois Central R.R. is contemplating the construction of a third track between Duquoin and Centralia to take care of the ever increasing coal traffic over that division. At the present time a third track is maintained between Du Bois and Duquoin, but the completion of the track into Centralia would facilitate the handling of the heavy tonnage immensely.

W. C. Schroeder, who has been Chicago sales manager for the Union Colliery Co. of St. Louis, Mo., leaves that company May 1. He is not yet ready to announce a future plan now taking form. Mr. Schroeder was a man of ripe experience in selling midwestern coals through Iowa before he went into the bigger selling field centering at Chicago, where he did a great deal to make well known the name of Kathleen coal produced and sold under the direction of Eugene McAuliffe, then president of the Union Colliery Co. This coal will hereafter be handled in Chicago territory by the Sheridan Coal Co.

INDIANA

Bids for 30,000 tons of coal were opened by the Ft. Wayne board of works recently. Eighteen firms were represented by the bids which range from $1.45 to $2.75 per ton. The contracts call for a regular weekly shipment from May 1 of this year to April 30 of next year. All bids were taken under advisement, the board members deciding that samples of the coal be submitted for their consideration. It is probable that the contract will be awarded soon.

Sealed proposals for approximately 7,500 tons of coal for the Auburn light and power plant were opened by the Auburn City Council recently. Thirty-three firms submitted bids. Any one of the estimates submitted will save the city at least $1 a ton, or nearly $8,000 for the year's supply. Proposals varied from $2 per ton for Indiana fourth vein (freight rate $1.83 a ton) to $3.40 per ton for Hazard No. 4 mine run (freight rate $2.90). The bids submitted will be considered soon.

The Calora Coal Co., with offices in Terre Haute, **has gone into the hands of a receiver** following a suit in the Superior Court of Vigo County by Mrs. Martha J. Jones, widow of the company's president, for settlement of account. John T. Reed, manager of the Indiana Refining Co., was appointed receiver and is ordered to sell all or any part of the property necessary to meet the demands of the creditors.

Considerable preparation is being made for the **Indiana coal traffic case**, to be heard soon before the Indiana Service Commission. The case affects the rates on Indiana mined coal for intra-state shipment. Cities in various sections of the state are compiling data which are being turned over to the Indiana State Chamber of Commerce, which will present the case through its traffic department.

The Akin-Burton Coal Co. has incorporated to produce and sell coal. Directors are Charles T. Akin, Sedgwick R. Akin and Charles E. Burton. The capital stock of the corporation is $50,000.

KANSAS

When the Jackson Walker Coal Co. closed its mine No. 16, near Pittsburg, **the miners petitioned Governor Jonathan Davis to compel the company to reopen it.** The petition carried the proviso, however, that the Governor should not put the matter before the Industrial Court. After other mines in the district were closed and other miners added their pleas the Governor promised a "personal investigation." Bernard Harrigan, Kansas commissioner for the Southwest Interstate Coal Operators' Association, said: "If the Governor will supply us with the market, we will run the mines." Operators add that the capacity of the mines being kept open is at least 10,000 tons a day more than is now being produced. Among the mines now closed in the vicinity of Pittsburg are Clemens Nos. 20 and 21, Sheridan Nos. 12, 14 and 16, Crowe No. 15, Girard Coal No. 7, Jackson Walker No. 16, Carbon No. 6, United States Nos. 1 and 2, Minden, Mine H; and one Liberal mine. **The Cherokee Coal Co.** within a few days **will close twelve of its mines** in Kansas.

KENTUCKY

The Pioneer Coal Co. of Kettle Island, whose tipple was recently destroyed by fire, has contracted with the Roberts & Schaefer Co., for a screen and loading booms to be installed in the new tipple which is expected to start up soon.

MARYLAND

In a recent issue of *Coal Age* it was stated that the **Equitable Fuel Co.**, Maryland Trust Building, Baltimore, had increased its capital stock to $10,000. **The company's capital has been increased from $20,000 to $30,000**, by the issuance of new stock.

Sealed proposals will be opened by the Superintendent of Lighthouses, Baltimore, at 2 p.m., June 5, 1923, **for furnishing anthracite No. 3 and bituminous steaming coal** for stations and vessels, 5th Lighthouse District, as required during the fiscal year ending June 30, 1924. Information on application.

MINNESOTA

Representatives of the Federal Fuel Distributor have been interviewing representatives of the coal trade in the Twin Cities **to ascertain what could be done to avert further coal shortages.** They interviewed wholesalers and retailers separately and, according to report, obtained some of the family gossip which each side furnishes against the other. They learned that there would be no autumn fuel shortage if the wholesale trade would buy coal earlier in the season, if the consumer would buy a three months' supply at once, and if dealers would buy earlier, thus providing steadier employment for the miners, resulting in more satisfaction and probably lower prices because the mines would be kept longer in operation and railroads would be able to handle coal better in summer than in winter. It was further unearthed that dealers did not buy early because they feared a price drop which might leave them with high-priced coal on which to take a loss. All of which is about as fresh as if it had been deciphered among some of the hierophyphs exhumed with King Tut-Ankh-Amen.

Fargo, N. D., and its sister city across the line, Moorehead, Minn., **are about out of fuel.** Neither city has had hard coal for some time, and now soft-coal substitutes have about reached their bottom—including lignite, briquets and coke.

MISSOURI

Announcement has been made at Bethany, that **a large New York syndicate is considering opening a coal mine at Cainsville** and using the fuel to generate power in that town for a large light and power system.

John Gantner and son, Leonard, have obtained a lease on the Schler farm, three miles southwest of Boonville, where they have unearthed a rich vein of coal.

The City Council of Bethany has announced that **a test of two months will be made with Illinois coal** at the city power plant to determine whether a saving in the fuel bill can be brought about. At present Iowa coal is being used, but no additional contracts will be awarded until the test is made.

NEW JERSEY

The State Board of Taxes and Assessment has **reduced from $1,170,145 to $313,662 the assessment** on personal property levied by the Saddle River, Bergen County, Tax Board **against the Pennsylvania Coal Co.** for 1922. The assessment was levied against coal mined and stored in the Township of Saddle River. The State Board held that the method of assessment followed by the Township Board was erroneous.

Retail dealers in Trenton have **reduced the prices for domestic sizes of anthracite** $1 per ton and 75c. for pea coal, making the prices $13.50@$14 for the larger coals and $11.15@$11.50 for pea coal.

NEW YORK

The Chicago Pneumatic Tool Co. announces that Robert F. Eissler, who, during the past two years, has been assistant to the vice-president, assumed his former position as district manager at Pittsburgh April 1. The appointment was announced of Nelson B. Gatch as assistant to the vice-president, headquarters at New York, succeeding Mr. Eissler. The appointment also was announced of William C. Straub as district manager of New York, to succeed Mr. Gatch, promoted.

In discussing **New York City's investigation of the coal situation** at a meeting of the Board of Estimate, April 12, Mayor Hylan said that if the Walker-Donohue transit bills are passed he will stop the Berwind-White Coal Co. from supplying the city's transit lines with fuel. The discussion that led to these remarks was the debate on a date for the city's hearing and investigation of the fuel situation that was blamed for the inadequate supply and the high prices for coal during the winter. The hearing will be held in the Board of Estimate chamber. The date will not be fixed until after the fate of the Mayor's transit bills is known. Neal J. Ferry, of the miners' union, testified before the board and said the operators were to blame for recent conditions.

The Burns Brothers plan of reorganization is expected to make its official appearance soon. No financing other than the offering of common stock to present holders will be necessary. The plan is said to call for retirement of two classes of preferred in exchange for present class A stock. Class A holders will receive free one share of the new common, which will pay a dividend of $2.50 a year for each share of A stock. In addition present holders will be offered an opportunity to subscribe to the new common at $35, proceeds to be used for retiring present outstanding preferred shares. The additional common shares, paying $2.50 a year, will mean a total return on present A stock of $10.50 a year.

OHIO

The Plainview Coal Co., Cambridge, capital $50,000, has been incorporated by A. V. Ferguson, C. F. Crow, A. T. Saviers, D. M. Wilson and Charles J. Bushdale.

The P. & O. Mining Co. has closed its Cincinnati office and **E. Manning,** who had charge, returned to Louisville, where he will be connected with the **Ballard & Manning Coal Co.**

Bids will be opened May 7 by the Columbus Board of Education for 12,000 tons of run of mine bituminous coal for the public schools for the coming winter. Active bidding is expected on this business.

The City Board of Purchase of Columbus has rejected all bids for 13,000 tons of nut, pea and slack opened recently because they were believed to be too high. Bids on the same tonnage for the municipal light plant, garbage disposal plant and the waterworks department will again be opened May 2.

Acting on an invitation extended by the Cincinnati Coal Exchange, officers of the **Michigan, Ohio and Indiana Retail Coal Dealers Association, will hold their annual convention in the Queen City** and have named May 22, 23 and 24 as being the dates acceptable. B. F. Nigh, secretary of the association, visited Cincinnati last week to make the preliminary arrangements.

The Besola Coal Co., St. Clairsville, capital $25,000, has been incorporated by W. E. Lahm, J. O. Somers, B. H. Beatty, Laura L. Somers and Emma C. Beatty.

PENNSYLVANIA

The Hillman Coal & Coke Co. has ordered 300 55-ton cars from the Standard Steel Car Co. and 300 70-ton cars from the Pressed Steel Car Co. The orders involve about $1,350,000.

H. J. German was elected president of the **Montour Railroad Co.** by the board of directors, effective April 3, 1923.

A six-hour day and minimum pay of $10 a day was predicted for the miners by George Isaacs, vice-president of District No. 1, United Mine Workers, at a mass meeting of miners held in Wilkes-Barre on April 2 in observance of the Eight-Hour Day.

Charged with being responsible for the mine gas explosion at Spangler, Cambria County, in which 77 men lost their lives, **W. H. Young,** superintendent of the Reilly mine, and **O. J. Flanagan,** mine foreman, **have each entered $1,500 bail for trial at court.** The men are charged with involuntary manslaughter. The explosion occurred in November, 1922.

The Judiciary Committee of the State Legislature has **reported affirmatively the Burns bill** giving the Public Service Commission power over the distribution and price of coal in this state. The vote as reported was 11 to 6. Protests against the bill have been made, coal operators contending that it will impose considerable additional expense, inasmuch as it will increase the cost of mining and also the cost to taxpayers.

There were twenty-three "outlaw" strikes in anthracite mines between Dec. 16, 1922, and Feb. 28, 1923, which involved suspension of work by 25,825 men, who lost $732,544 in wages, according to figures just compiled by the Anthracite Bureau of Information. The tonnage lost in the period of inactivity was in excess of 243,000 tons. "In the majority of the cases the cause for the strike was an attempt to enforce union discipline rather than any grievance against the companies," the statement of the operators said. "Under the agreement, all of the disputes leading to these strikes should have been settled by reference to the Conciliation Board."

Bituminous interests joined with the representatives of the anthracite regions to **oppose the Kohler mine-cave bill, the bill compelling coal companies to permit engineers employed by surface owners to enter the mines for the purpose of inspection and a third bill prohibiting the laying of gas pipes over mined-out areas.** A hearing on the bills was held April 10 and Representative Kohler, sponsor of all three measures, fought a lone battle before the House subcommittee of the Mines and Mining Committee. The bills were opposed by P. F. Murphy and G. B. O'Hara, of the Glen Alden Coal Co.; G. P. Gallagher, Lehigh Valley Coal Co.; P. H. O'Brien, Pennsylvania Coal Co., and Edward Griffiths, Lehigh & Wilkes-Barre Coal Co.

The Fowler full-crew bill, introduced in the State Legislature by David Fowler, **is being supported by the so-called anthracite bloc.** It is said they will vote as a unit in favor of the bill to put it on the calendar.

Sealed proposals will be opened by the Superintendent of Lighthouses, Philadelphia, Pa., 2 p.m., May 15, 1923, **for anthracite and bituminous coal,** gasoline, acetylene and acetone for the fiscal year 1924. Information on application.

Production for the six Johnstown mines of the Cambria Steel Co. for the month of March was 222,325 tons, which is the largest tonnage ever produced from these mines in a single month and is 35,000 tons greater than the previous record month, January, 1923. The production of the Slickville mines, in Westmoreland County, for the same month was 61,040 tons, making a combined tonnage for Slickville and Johnstown of 283,365 tons. The mines of the Union Coal & Coke Co., subsidiary of the Midvale Steel & Ordnance Co., located in Washington County, produced 158,743 tons, making a grand total of 442,108 tons for the entire department. J. C. H. Lubken is general superintendent of coal mining operations for the Cambria Steel Co, and the subsidiary concerns. A daily record for the Johnstown mines was made on March 28, when production reached 8,897 tons, and the combined record of 18,004 tons for all the mines was made the same day.

The men at the Lilley Coal & Coke Co., a union mine in Washington County, on the Monongahela River and the Pennsylvania R.R. a short distance below West Brownsville, have been on strike for the past three weeks in violation of their agreement. The trouble was caused by two of their men leaving their employ last autumn to work as union organizers in the non-union Connellsville coke region, and then coming back about three weeks ago and wanting their old jobs back, which were denied them. There is no more sign of a termination of the trouble than when it started, and **the strikers have been ordered by the company to return to work** in accordance with their agreement or vacate the company's houses.

Shipments of anthracite for the month of March, as reported to the Anthracite Bureau of Information, Philadelphia, amounted to 7,183,518 gross tons, as compared with 6,778,667 gross tons during the corresponding month last year, an increase of 404,851 tons, or about 6 per cent. Shipments of anthracite have exceeded 7,000,000 tons only six times previous to March of this year, and these were all in the war years of 1917 and 1918, when the washery tonnage was much more of a factor than it is at the present time. The March shipments exceeded those of February this year by 1,231,805 tons, or 20.7 per cent. Shipments by originating carriers were as follows, in gross tons:

	March 1923	February 1923
Phila. & Reading	1,370,476	1,206,538
Lehigh Valley	1,279,599	1,097,351
Jersey Central	622,710	521,430
Lackawanna	1,146,217	957,612
Delaware & Hudson	907,099	629,514
Pennsylvania	542,167	483,466
Erie	818,817	712,210
N. Y., O. & W	192,247	169,176
Lehigh & New Eng	304,186	174,416
Totals	7,183,518	5,951,713

The Bethlehem Steel Co. has absorbed the coal properties of the Midvale Steel & Ordnance Co. with the amalgamation of the steel companies. Thus the Acme, the Marianna and the Hazelkirk mines of the Union Coal & Coke Co., formerly having offices in Bentleyville, are now part of the Bethlehem Mining Co. with offices at Ellsworth.

The Judge Coal Co. of Scranton, with banks containing 1,500,000 tons of coal at Jessup, has recently incorporated with the following officers: Ed. A. Judge, president; Hubert Gordon, secretary; John J. Bolan, treasurer, and George Bell, superintendent.

The Tip Top Coal Co., of Scranton, with an operation at Scotch Valley, Columbia County, has incorporated with the following officers: W. L. Henwood, president; Boyd A. Musser, vice-president; Alfred E. Lester, treasurer; George E. Schultz, secretary, and E. A. Jones, superintendent.

The following companies were incorporated at the State Department, Harrisburg, recently: **Eureka Mining Co.,** DuBois, capital $15,000; James Jones, DuBois, treasurer; William Harringer, James Jones and J. J. Pentz, DuBois, incorporators. **The Miners Powder & Supply Co.,** Latrobe, $10,000; H. L. Donaldson, Ligonier, treasurer; John J. Crumbaugh, Latrobe; S. S. Brownfield and H. L. Donaldson, Ligonier, incorporators. Purpose: Dealing in explosives and mine supplies. **George A. Clark, Inc.,** Hastings; $5,000; George A. Clark, Hastings, treasurer; L. S. Clark and Louise Clark, Cherrytree, and George A. Clark, Hastings, incorporators. **Red Dog Coal Co.,** Pittsburgh; $10,000; incorporators, S. M. Kintner, H. Talbot Peterson and A. J. Loeffler, Pittsburgh.

The Cement Gun Co., Inc., Allentown, **announces the resignation of W. J. Roberts as president** of the company and the election of B. C. Collier to fill the vacancy. Mr. Collier has for several years occupied the position of vice-president and general manager of the company.

The stockholders of the **Glen Alden Coal Co.** at their annual meeting held at Scranton re-elected the following directors: F. J. Platt, F. H. Hemelright, John H. Brooks, J. Hayden Oliver and W. W. Inglis. At the reorganization meeting the following officers were re-elected: W. W. Inglis, president; S. D. Dimmick, vice-president and general manager; George England, secretary-treasurer; James L. Dodson, assistant secretary-treasurer. Mr. Inglis stated after the session that the matter of dividends was not considered by the directors.

The Rochester & Pittsburgh Coal & Iron Co. reports for 1922 gross earnings of $4,297,327; net profit after expenses, depreciation, etc., $556,658, and a surplus after cash dividends of $316,658. The balance sheet as of Dec. 31 last shows cash of $416,751, accounts receivable $4,001,927, accounts payable $3,688,503, profit and loss surplus $1,848,604 and total assets and liabilities of $16,380,763.

Reports from Somerset County, where an attempt was made to call out the non-union miners on strike on April 1, are to the effect that **there has been no drop in production.** The shipments on the last four working days of March were 265, 277, 219 and 168 cars respectively, while on the four first days of April there were 91, 205, 275 and 260 cars, respectively. The low shipment on the first day was due to Easter Monday, when but few of the foreign miners work at any time.

J. C. H. Lubken, retiring head of the Midvale-Cambria mines, was the guest of honor at a farewell gathering held at the Fort Stanwix Hotel, Johnstown, sixty officials and associates in the Cambria Steel Co. attending. Greetings also were extended to the new officials, **T. R. Johns,** manager of the Bethlehem coal mines, and Samuel Steinback, new division superintendent at Johnstown. Frank Horton, superintendent of mines at Johnstown, was toastmaster. Charles Young, mining engineer, T. R. Johns, of Bethlehem, and Mr. Steinback spoke. During Mr. Lubken's service in the Johnstown district he supervised the opening of seven mines, notably the two Rosedale shaft mines.

L. V. Walsh, for about twenty years treasurer and general manager of sales of the Pittsburgh Shovel Co., Pittsburgh, has resigned. **C. B. Steffey,** since 1917 secretary of the company, has been appointed general manager of sales and also retains his office as secretary.

UTAH

There are various reports that Los Angeles capitalists are soon **to develop coal lands around Provo,** county seat of Utah County. A big smelter also may be erected in that county, but details of this enterprise are meager.

VIRGINIA

Suits aggregating approximately $175,000 have been filed by the Norfolk & Western Ry. against four coal concerns with agents in Norfolk, for alleged demurrage due on carloads not released from the railroad tracks within the five-day free period. Beyond that period the railroad claims $2 per car per day. The suits, with their amounts are: Dexter & Carpenter, $1,990; West Virginia Coal Co., $2,183.06; Jewett, Bigelow & Brooks, $46,320; Algonquin Coal Co., $124,012.63.

WASHINGTON

The College of Mines of the University of Washington offers **five fellowships for research in mining, metallurgy and ceramics** in co-operative work with the Bureau of Mines. The fellowships are open to graduates of universities and technical schools who are qualified to undertake research investigations. The value of each fellowship is $810 per year of twelve months beginning July 1. Applications, which should include a copy of the applicant's collegiate record, should be sent to Dean Milnor Roberts, College of Mines, University of Washington, Seattle, not later than May 10.

WEST VIRGINIA

The Lost Creek Coal Co., of Clarksburg and Pittsburgh, has purchased the holdings of the Elk Smokeless Coal Co., owning a large tract of smokeless coal at Holley Junction, near Richwood. The consideration was not made public.

Miners of the Hutchinson Coal Co. are at work again after an unauthorized strike at the Mount Clare mine of the company in Harrison county, the strike growing out of a misunderstanding as to the terms of the new contract.

A death blow is believed to have been dealt to the Sutphin bill, having for its object the repeal of the law creating the West Virginia state police, in the House of Delegates on April 9 when **a motion to take the bill up out of its order** and advance it on the calendar **was decisively defeated** by a vote of 57 to 31. The bill had been before the House Judiciary Committee and was strongly supported by the United Mine Workers as well as by the State Federation of Labor. The miners' organization had counted on having a small margin over the opponents of the bill.

The Atlantic Smokeless Coal Co., whose annual meeting was recently held in southern West Virginia, has increased its capital stock from $250,000 to $300,000.

The Appalachian Power Co., Glenlyn, **is increasing its boiler-plant capacity** in order to keep up with the demand for electricity by the coal mines. Four Westinghouse underfeed stokers will fire four 1,232-hp. B. & W. boilers with Pocahontas coal. The installation will include power-operated dump grates, extension sidewall tuyeres; turbines will drive the stokers as well as the fans while Diamond double chain will transmit power from the turbines to the stokers.

The West Virginia Rail Co., Huntington, has decided **to add another unit to its plant** for the manufacture of frogs and switches, steel mine ties, and steel mine timbers. This addition will enable the company to furnish the mining industry complete track equipment from one point of shipment. This addition will cost in the neighborhood of $250,000 and the company hopes to be in position to make deliveries of this class of material within six months.

The Pan Coal Co. was awarded $25,566 in damages in its suit against the Garland Pocahontas Coal Co. a few days ago in southern West Virginia. A motion to set aside the verdict was taken under advisement by Judge I. C. Herndon. The plaintiff claimed damages in the sum of $100,000, alleging that the defendant had removed 27,000 tons of coal from plaintiff's land and had otherwise damaged the property. The jury decided upon 12,000 tons as the amount taken from the mine and estimated its value at $2 per ton.

The Eagle Island Coal Co. has just finished work on a **steel tipple and 700-ft. conveyor** at Crites, in the Logan field. In order to mine coal from an additional seam in Logan County the **Bengal Coal Co. has constructed a new tipple** at Kistler. The **Draper Eagle Coal Co. is constructing a modern steel tipple** near Logan. **The H. T. Wilson Coal Co.** is another concern in the Logan field which **is enlarging** the scope of its operations, being engaged in sinking a shaft to another vein. **The Island Creek Coal Co.**, one of the largest companies in the state, is now **engaged in opening several additional mines** on the acreage near Whitman. As a result of these improvements as well as through the installation of additional mining equipment, it will be possible to ship more coal than ever from the Logan field if car supply and market conditions are at all satisfactory.

The Riverside Coal Co. has been organized at Morgantown by George W. Simpson and West Virginia parties, with a capital stock of $150,000.

WISCONSIN

Formal announcement is made by **the Central Coal Co.** that it **has sold its coal docks** on the Menomonee River, Milwaukee, and at Escanaba, Mich., **to the Industrial Coal Co.**, of Pittsburgh, Pa. The consideration is given as "more than $500,000." It is said the Industrial Coal Co. is backed by Burns Bros. of New York, and that a $10,000,000 merger of coal interests in Pittsburgh, New York and the Northwest is being promoted. The Central Coal Co. will confine itself to the handling of Illinois coal by rail.

A bill before the Wisconsin legislature which would impose an occupational tax on coal on the docks at receiving points in the state, is being fought. **The bill would put a tax on dock coal but would not affect coal shipped by rail.**

Paul H. Pressentin of the Wisconsin Fuel Administration, **urges dealers to begin a campaign at once for coal orders for delivery when Lake cargoes arrive.** He suggests a system of credits when conditions warrant such action. He holds that cleaner and better coal, with smaller moisture content, will be secured if orders are placed early. Mr. Pressentin warns dealers against brokers who booked their orders during the past season and failed to fill them, or who cut in on their local trade. He says country dealers were at least entitled to a reasonable portion of their orders.

WASHINGTON, D. C.

A collection of samples of anthracite for the U. S. Coal Commission has been gathered by the Bureau of Mines for the purpose of **determining the percentage of coal, bone and slate contained in the supplies arriving at Washington.** Other coal information given out by the bureau includes a report with regard to the coal requirements of the various hospitals of the United States Veterans' Bureau. The Bureau of Mines also is collecting tipple samples at twenty coal mines on government property in Oklahoma.

CANADA

General repairs to approximately 300 lineal feet of the timber superstructure of **West pier** together with minor repairs to other portions of the departmental works at Rondeau, Ont., is to be undertaken during the fiscal year 1923-24. Ten thousand dollars has been allotted for this purpose.

Approximately half of the coal used by the Pere Marquette and Canadian National railways in western Ontario is imported by car ferry and collier in connection with the operations of the Lake Erie Coal Co. and the Marquette & Bessemer Navigation Co. between Rondeau and Conneaut, Ohio. The imports in 1921, consisting largely of coal, amounted to 250,450 tons.

The United Gas & Fuel Co., of Hamilton, Ont., has let contracts for the **construction of a byproduct-coke-oven plant** representing an investment of $2,500 000 to be completed by Nov. 1 which will give employment to 250 men. The plant will be erected by the Hamilton By-Product Coke Oven Co. which has a contract with the Semet-Solvay Co. of Syracuse, N. Y., under which they will be able to adopt the latest designs and processes for the manufacture of coke. The work has been rendered necessary by the decrease in the supply of natural gas, on which the United Gas & Fuel Co. was largely dependent.

News that Hamilton, Ont., is to have a $2,500,000 byproduct coke-oven plant has revived **talk of another oven at Ojibway**, near Windsor, where the Canadian Steel Corporation has spent millions on its steel plant. Completion of the project, it is stated, means another byproduct plant where most of the product will go to feed the blast furnaces, but it is believed there will be a surplus for domestic use.

Floating docks may soon be placed at Prince Rupert. B. C., for the handling of coal shipments from the Cadomin mine section of Alberta. It is stated that 2,000 tons a day will be provided from this field to supply the mercantile demands at the northern provincial port.

Since the disaster of last February in No. 4 mine, Canadian Collieries (D), Ltd., Cumberland, B. C., there have been **a number of prosecutions for infractions of the Coal Mines Regulation Act** by underground workers. In one case a Montenegrin miner was fined $10 and costs for taking into the mine a Wolf safety lamp that had not previously been examined by a competent person. A Chinaman was sent to jail for thirty days for taking underground a key to an electric safety lamp. It is understood that other prosecutions under the act will follow.

The Canadian National Railway is considering the establishment of reduced rates on coal from Alberta in order that the coal can compete with the American product in Ontario and Quebec, according to Sir Henry Thornton, president of the road, in a recent interview at Ottawa. The most advantageous time to bring out coal would be between April and August, Sir Henry declared.

The United Mine Workers of the maritime provinces district have affiliated with the Third Internationale, an envoy having been sent to Russia for that purpose. The district is defying the order of International President John L. Lewis to withdraw from the Internationale.

Traffic News

The embargo placed by the New York Central R.R. **against** all freight destined to points on or **via the New York, New Haven & Hartford R.R. and Central New England Ry. was entirely cancelled** April 11.

The embargo placed by the Erie R.R. on carload and less carload freight from connections and Erie system stations for or via the D. & H., Binghamton, except livestock, anthracite coal, perishable freight, bituminous coal for railroad supply, field and garden seeds and such other freight as permitted by the D. & H. subsequent to March 2 was **modified April 10** to allow to go forward all freight for delivery at points on D. & H. lines via Binghamton.

On account of accumulation an **embargo was placed** March 31 by the New York Central R.R. against the acceptance of all carload and less than carload freight from all New York Central R. R. stations and from connections at all junctions for points on or via the Boston & Maine R.R. except livestock, perishable freight, Boston & Maine R.R. fuel and supplies and freight consigned to an officer of the U. S. Government.

In order to effect reduction in accumulation of cars for the B. & M. R.R. an **embargo was placed April 7 by the Boston & Maine on all coal, except railroad supply coal**, from and via the Delaware & Hudson Co., New York Central R.R. and Rutland R.R. at all junctions. This embargo automatically expired April 16, 1923.

On account of accumulation **an embargo has been placed by the New York Central R.R. against all shipments of coke** consigned, reconsigned or intended for the **McKinney Steel Co.**, Charlotte, N. Y. Shipments originating principally at Cleveland, Ohio.

The embargo placed by the New York Central R.R. against all freight from connections at 60th or 68th Street, New York City, Weehawken, National Junction or Harsimus Cove, for points on or via the Boston & Albany R.R. **was entirely cancelled April 11.**

To prevent an accumulation the New York, New Haven & Hartford R.R. on April 7 **embargoed all freight coming from the B. & A. and B. & M.** for delivery on bulk (team) tracks of the N. Y., N. H. & H. at Boston, Mass., or in Boston switching district.

Newport News is making a determined effort to obtain lower freight rates on anthracite. The present rates of $4.30 and $4.96 per gross ton to Newport News via the two available routes are higher by 90c. per ton and $1.56 per ton than the corresponding rate in effect to Norfolk and Richmond, Va. It is contended that Newport News is located on the same harbor as is Norfolk and is geographically nearer the coal field and customarily takes the same rates on other traffic as do Norfolk and Richmond. The position of the Richmond interests is not to oppose a rate on anthracite to Newport News which is no greater than the rates they enjoy, but the Retail Coal Merchants' Service Bureau and the Chamber of Commerce of that city have intervened to oppose any order of the commission which might be interpreted by the carriers as justification to increase the Richmond rate.

Colonel T. Q. Ashburn, director of inland water transportation of the War Department, made a recent visit to Minneapolis, Minn., announcing that **the government would institute a barge service between the "Twin Cities" and New Orleans,** to carry freight at 80 per cent of railroad freights. Four oil-burning packets, equipped to carry 160 tons of freight, will be installed in the service by June 15, according to J. S. Brodie, president of the River Transit Co. The contract has been let to the Midwest Boat & Barge Co., of Grafton, Ills., for them. The packets will be steel, stern-wheel, and will carry 100 tons each. Colonel Ashburn is to return to the Twin Cities soon in search of freight for the government barges. The government will use the barges, which have been held by Colonel Goltra, of St. Louis, and were recently ordered seized from Goltra for non-performance of contract.

Rates on coal from certain mines on the Kanawha, Glen Jean & Eastern R.R. to destinations on the Chesapeake & Ohio Ry. and its connections have been **found to be unreasonable.** Any rate exceeding the group rates contemporaneously maintained from branch-line points on the Chesapeake & Ohio in the New River district to the same destinations will be regarded as unreasonable.

No less than three roads, the Chesapeake & Ohio, the Kanawha & Michigan and the Baltimore & Ohio, **seek entrance to the Nicholas County coal field.** The first two have already applied to the Interstate Commerce Commission for a certificate of necessity permitting them to extend their lines into this field. Nicholas County coal lands are largely undeveloped, because of their inaccessibility.

The Interstate Commerce Commission has set May 28 as the date of the hearing in connection with the case of the **Ragland Coal Co. vs. the Virginian Ry.** The hearing will be in Washington before Examiner Hillyer.

Rates on coal from Brookside and Drifton, Ala., to Sloss, Ala., have been found unreasonable to the extent that they exceeded $1 per ton from Brookside and $1.10 from Drifton. The finding was made by the Interstate Commerce Commission in the case of the Sloss-Sheffield Steel & Iron Co. vs. the Director General.

The Interstate Commerce Commission has decided that **rates on buckwheat No. 2 and smaller from the Wyoming field to the Albany district of New York have been unreasonable** and unduly prejudicial. An order has been issued to the N. Y., O. & W. Ry., the D. & H. and the Boston & Maine to desist from present rates on or before July 6 and to establish by that date rates which shall not exceed the rates maintained by the D. & H. from the Wyoming field to the Albany district on its own direct shipments. The West Virginia Pulp & Paper Co. is declared entitled to reparation under the finding.

The Coal, Coke & Iron Ore Committee, Central Freight Association Territory, announces a public hearing 10 a.m., April 26, at the Chamber of Commerce Building, Pittsburgh, Pa., **to consider cancellation, on account of no movement, of rate of $2.39 per net ton on bituminous coal,** carloads, from mines on the Sandy Valley & Elkhorn, Long Fork and Millers Creek Railroads, to stations on the Lorain, Ashland & Southern R.R., Ashland, Ohio to South Amherst, Ohio, inclusive.

Proposed increased rates on coke from Chicago, Peoria and St. Louis to destinations in southwestern Missouri and eastern Kansas have been found by the Interstate Commerce Commission **not to be justified.**

General Superintendent E. L. Bock of the western division of the Chesapeake & Ohio Ry. stated a few days ago that the recently authorized purchase of **2,000 new 70-ton coal cars** will enable the road to materially increase its car supply in the coal fields. Mr. Bock also states that the road Chesapeake & Ohio planning to add materially to its equipment also is engaged generally in rehabilitating the coal cars heretofore in use.

Rates on bituminous coal from points in West Virginia to Elizabethport and Jersey City have been found unreasonable by a Commerce Commission examiner. The attack on the rates was made by the Seaboard By-product Coke Co.

An enterprising coal man, searching the code of West Virginia, has brought to light a statute long overlooked, regulating car supply within the state. A section provides that "It shall be unlawful for any railroad company to engage, directly or indirectly, in the business of buying and selling coal or coke, or to promise, pledge or lend its credit, money or other property or thing of value to another, either natural or corporate, engaged in such business, but nothing herein shall prevent such corporation from purchasing such articles for its own consumption or when it is the owner of any such commodities from selling and shipping the same; provided in doing so, such corporation shall not discriminate in rates, distribution of cars or otherwise and against other shippers of like commodities on its lines . . . Every railroad corporation along whose lines of railroad the industries of mining coal or manufacturing coke is carried on, shall, without discrimination between or against shippers and without unnecessary delay, make a reasonable provision for the transportation of all such coal and coke offered for transportation over its railroad, and no such railroad corporation shall discriminate in rates, distribution of cars or otherwise against or among shippers of coal or coke offered for shipment on its line or lines."

Representatives of the Elkhorn & Hazard Coal Co., appeared before the State Railroad Commission, at Frankfort, Ky., April 12, in a **plea for reduction of rates from the Whitesburg district to points within the state,** holding that rates now in effect prevent competition with some other state fields.

Association Activities

Grand Rapids Coal Dealers' Association

The Grand Rapids Coal Dealers' Association at a recent meeting elected the following officers: President, Isaac VanHeulen; Vice-President, W. J. Breen; Secretary, C. F. Hatch, and Treasurer, A. B. Knowlson.

Obituary

Alexander Dick, general manager of the Dominion Coal Co., Montreal, Canada, died suddenly April 12 in New York of heart disease while seated in restaurant with friends. Mr. Dick was fifty years old.

John Cain, 47, superintendent of the National coal mine, near West Terre Haute, died suddenly at his home early in April of heart trouble.

Horace O. Stone, lawyer, inventor and chief assistant to William H. Taft in the Presidential campaign of 1908, died April 10 after a stroke of apoplexy suffered while he was sitting in the Union League Club, Chicago. Mr. Stone was born in the Kalamazoo County, Michigan, in 1852. He invented a glass device to prevent damage by freezing of water in engines, methods of producing coke from poor coal and methods of effecting saving in blast furnaces.

Catesby Woodford, 74 years of age, Paris, Ky., prominent as a big coal land owner on the Hazard field, and more prominent as owner, breeder and racer of thoroughbred horses, died at his winter home at Fort Meyer, Fla., on April 8, the remains being taken to Lexington for interment. "Raceland," his Kentucky home at Paris, was one of the finest estates in Kentucky.

Coming Meetings

Pennsylvania Retail Coal Merchants' Association will hold its annual meeting May 23 and 24 at Wilmington, Del. Secretary, W. M. Bertolet, Reading, Pa.

American Association of Mechanical Engineers will hold its spring meeting at Montreal, Quebec, Canada, May 28-31. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

National Association of Purchasing Agents will hold its eighth annual convention and Informashow at Cleveland, Ohio, May 15-18. Convention headquarters, room 219, Hotel Winton, Cleveland.

The National Association of Manufacturers will hold its 27th annual convention at the Waldorf-Astoria, New York City, May 14-16.

New England Coal Dealers' Association will hold its annual meeting at Providence, R. I., June 13-15. Secretary, C. R. Elder, Boston, Mass.

National Retail Coal Mechants' Association will hold its sixth annual convention June 25, 26 and 27 at Scranton, Pa., with headquarters at the Hotel Casey. The registration fee of $15 will include all meals except breakfast, transportation to and from the mines which will be visited, and the banquets. The only other expenses to be incurred will be hotel room and transportation to and from Scranton. Executive secretary, J. E. O'Toole, Philadelphia, Pa.

National Safety Council will hold its twelfth annual safety convention at the Buffalo Statler Hotel, Buffalo, N. Y., Oct. 1-5. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

International First-Aid and Mine-Rescue meet will be held Aug. 27-29, at Salt Lake City, Utah.

American Institute of Electrical Engineers will hold its annual convention June 25-29, at Swampscott, Mass. Secretary F. L. Hutchinson, 29 West 39th St., New York City.

Coal Mining Institute of America will hold its annual meeting Dec. 19, 20 and 21 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Chamber of Commerce Building, Pittsburgh, Pa.

The Virginia Coal Operators' Association will hold its annual meeting on April 21 at Norton, Va. Secretary, G. D. Kilgore, Norton, Va.

International Railway Fuel Association will hold its spring convention at the Hotel Winton, Cleveland, Ohio, May 21-24, Secretary-treasurer, J. G. Crawford, Chicago, Ill.

The American Mining Congress will hold its twenty-sixth annual convention in conjunction with the **National Exposition of Mines and Mining Equipment,** Sept. 24-29, at the Milwaukee Auditorium, Milwaukee, Wis. Secretary, J. F. Callbreath, Washington, D. C.

Indiana Retail Coal Merchants' Association will hold its annual meeting April 25 and 26 at the Claypool Hotel, Indianapolis, Ind. Secretary, R. R. Yeagley, Indianapolis, Ind.

American Society for Testing Materials will hold its annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City N. J., beginning June 25 and continuing throughout the week. Secretary, E. Marburg, Philadelphia, Pa.

The Colorado & New Mexico Coal Operators' Association will hold its annual meeting June 20 at Denver, Col. Secretary, F. O Sandstrom, Denver, Col.

The Electric Power Club's annual meeting will be held at the Homestead, Hot Springs Va., June 11-14. Executive secretary, S. N Clarkson, Cleveland, Ohio.

National Foreign Trade Council will hold its annual conference May 2-4 at New Orleans, La. Secretary, O. K. Davis, 1 Hanover Square, New York City.

The eleventh annual meeting of the Chamber of Commerce of the United States will be held in New York City May 7-10.

National Coal Association will hold its sixth annual convention June 19-22 at Atlantic City, N. J. Assistant secretary, C. C. Crowe, Washington, D. C.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 23 NEW YORK, APRIL 26, 1923 Number 17

The Injustice of Impartiality

DISCUSSING "Bituminous Coal Problems" in the current issue of the *Harvard Business Review*, C. E. Bockus, president of the Clinchfield Coal Corporation, gives expression to many truths about the soft-coal industry in a frank and engaging manner. No coal operator in recent years has told so much in print about his problems and given the public such a comprehensive picture of the situation. Being an operator of non-union mines he does not stress though recognizing the complications that are introduced nationally by large-scale strikes in the organized fields. Overdevelopment and the effects of insufficient transportation are set down as basic problems in his field.

Mr. Bockus quite pertinently ventures the suggestion that in seeking remedies, as by the present U. S. Coal Commission, "it is going to be difficult to make consumers buy and store coal when they believe there is a falling market or to make producers sell for a lower price than they can obtain." He thinks that if some plan could be devised by which a regular contract shipper of coal had some advantage in his railroad-car supply over a "sporadic" shipper who comes into the field only when spot prices are high it would help. It is, in fact, the almost universal experience of the older, well-established companies, whose business has been built up on sound lines, that at the very times when their regular contract customers are in most urgent need of coal they are least able to ship the coal. When the occasional producer—the intermittent operator—finds a market for high-priced coal he demands and receives a share of the cars and takes a portion of the labor. The buyer, forced to take a pro-rata share from his regular supplier because of reduced car supply, must then purchase spot coal to fill his requirements.

This is the old story. The railroads meet it by assigning cars, thus getting the preference, and furnishing evidence that they know that a short coal supply is not the result of lack of coal but of cars and the transportation for which they, the railroads, are responsible. The public utilities regularly cover their needs for coal by contracts and they have repeatedly said that they would be satisfied if they could be sure of getting the coal they had bought. They too would like assigned cars. Mr. Bockus wonders whether his suggestion is "too much like 'assigned' cars, that anathema of most coal operators," and then answers for himself by stating that he would rather have the railroads get their coal in times of stress by assigning cars than by confiscating coal he has shipped to commercial customers. Is it too much to say that the railroads, without assigned cars, fill out the deficiences in their supply by *taking* spot coal, for they pay the invoice price on coal confiscated, and the commercial buyer *bids* for his share of the same spot coal? Of course, railroads have been charged with taking considerable pains to cut out of a yard of loads those cars for confiscation they had reason to believe were moving on low-priced contracts.

Those operators who will most heartily disagree with the idea that some prefence in transportation should be afforded contract shipments will be those who, unlike Mr. Bockus, would like to have their cake and eat it too. That is to say, there are many soft-coal producers who would favor a special supply of cars to protect their contract customers if on top of that they could have an allotment of cars in which to ship on the spot market. The practice of apportioning contract and spot shipments on the percentage of car supply is a case in point, though it finds some warrant from the fact that short working time increases costs of operation and thus may justify the attempt to obtain a higher average realization for the total product than would be afforded by contract prices. Mr. Bockus cites a particular instance where costs in December, because of short working time caused by lack of transportation, were 41c. per ton over May with full time, a factor in the business of the coal operator over which he has no control.

Subjects for Investigation

IF THE interest displayed by state legislatures is any indication of the public thirst for information about coal, the report and findings of the U. S. Coal Commission will be among the best sellers when given to the public. The latest—to come to our attention—is a bill introduced in the New York Assembly last week calling for a commission to investigate the coal industry and to ascertain why New Yorkers cannot get all the coal they want when they want it, and to report on how much coal New York needs, anyhow.

It is true that interest this summer may swing from coal to sugar, that in fact sugar is the real topic at Washington already. Later, if what the railroads prophesy as to transportation shortage next autumn comes true, there may be state commissions to inquire into speculation in railroad transportation. In passing it may be noted that it is going to be simpler for the purely political investigator to find a tail to which to attach his can in the case of sugar than in the case of coal. Some are blaming the tariff, others attribute soaring sugar prices to speculation in the established exchanges. Neither will suffice to explain away a situation in the coal industry.

It is not fair to lay all the politicians' interest in coal to politics. The people are greatly stirred up over the whole question and the local outbursts have an origin "back home." We believe the individual states would be best advised, however, to start their inquisitions into coal after they have the advantage of the national commission's findings. Thus not only would public money be saved but better results be assured. Since no generalization ever applies to Greater New York, an exception should be noted for Mayor Hylan's personal expedition into coal investigation, were it not that his questionnaires probably will be filed with the janitor.

Immigration in Relation To the Coal Industry

WHETHER or not a labor shortage is a good thing may be a timely subject for debate among employers in general industry but it is not going to trouble the soft-coal industry for some time. Judge Gary opened the debate in earnest a few days ago when he took occasion to oppose the present restrictive immigration laws and to urge a policy on the part of the country of taking in more foreign labor. He was perfectly frank in saying that the iron and steel industry needed more men and would like to have fresh supplies from abroad. Many other large employers hold the same views, for it is traditional in this country to draw raw labor from fresh stock.

Economists will long debate as to whether the admitted higher labor costs that will flow, and now are flowing, from a national policy of restricted immigration in a period of active demand are in the national interest. It seems quite certain now that there is a decided public opinion favoring the present plan, quite aside from what the labor interests think. The possibility of more complete and better assimilation of foreign labor already within our borders and the ultimate elevation of standards of living of these men is attractive and will have ample opportunity for trial before there is a change in national thought on this subject.

The anthracite industry is not overmanned. The high rate of production in these mines that has obtained since last September has been reached by hard work and no little overtime. With the soft-coal industry there is a different story. Production now is well above 10,000,000 tons per week, a figure that in a year will give more tons than the country has used save in three years—1917, 1918 and 1920. Yet the soft-coal mines are working but half time. There is labor at these mines sufficient to maintain 20 per cent more production and—at least on paper—labor to double the present rate.

In the face of this it does not seem possible that there can be a labor shortage at the bituminous-coal mines, yet such is possible locally. Just as there often is a car shortage and a car surplus at the same time, the country considered as a whole, so some operators may be short-handed while others have men idle. Districts such as Pittsburgh and Westmoreland, adjacent to active industrial centers, often experience a labor shortage while fields more isolated, as eastern Kentucky and parts of central Pennsylvania, have a surplus. Furthermore, a coal operator who obtains business that insures full running time, as railroad contracts, may be and often is short-handed at the same time that his neighbor, working a few days a week, has more men than he requires.

In certain respects coal-mine labor is fluid, as other labor. During the strike of 1922 union labor floated across the river from southern Illinois into western Kentucky, where the mines were the busiest they ever had been. During the dull period of 1921 union labor from the Pittsburgh district, where scales were fixed and inflexible and work scarce because of competition from mines with lowered wages, found employment in the Connellsville and other non-union fields near by, actually maintaining their residence in the meantime in the company houses in the union field. Operators in the Logan field of West Virginia often report an influx or exodus of labor, depending on the activity of the mines.

It is almost universally true that the older mines in a field have the greatest difficulty in maintaining their forces. Men seek the newer and easier places and during times of high prices find work in the small openings that do not hesitate to pay bonuses because not fearing to set precedents. Thus, despite the evident overmanning of the soft-coal industry, considered nationally, it is fully to be expected that if the present rate of output is maintained this summer, by autumn there will be the apparent anomaly of complaints of labor shortage from soft-coal mines. It must be apparent, however, that such a shortage cannot impair the ability of the industry to meet the country's demand for soft coal.

The Export Outlook

WHETHER the deadlock on the Ruhr is destined to result in such a coal famine in Europe, and indirectly in other countries, as will reopen in earnest the foreign market for exporters in this country depends largely if not entirely on how long the present situation endures. Information is lacking as to the degree to which the French have been able to revive coal production in that important field, but reports agree that no coal or coke is getting into Germany and that only driblets of coal and coke are finding their way west and north into France and Belgium.

Simultaneously with the stoppage of the Ruhr there is a definite revival of industry on the European continent, calling for more coal than last year, and with less available. France, Belgium, Germany and Italy first turned to Great Britain to fill the gap. The coal industry in that country, with 40,000 more workers than before the war, working at top speed, is able to produce at a rate between ten and fifteen million tons per year less than in 1913, when the output was 287,000,000 gross tons. The principal reason for this decline, of course, is the reduction from the 8- to the 7-hour day. Another factor is the lack of development, particularly of new mines. For the last five years the uncertainties of business and paucity of profits in the British coal trade have discouraged new investment in that field. It is a striking fact that with all the urgency of demand the exports of British coal in the first quarter of this year were less than in either the third or the fourth quarter of 1922.

There seems then to be little expectation of filling the widening gap between expanding requirements and decreased supply of coal abroad. The only other source competent to furnish the tonnage of coal that is, or will be, required is the United States. Buyers in Germany, Belgium, France, Italy and South America have been quietly covering their urgent needs on this side, at current market prices. So far there has been no precipitate rush for coal such as characterized 1920. A repetition of that avalanche of export business is not to be expected for two reasons: one is that the requirements for consumption over and above production on the other side is by no means so large as three years ago and the other is that shipping is abundant now and the demand will not be backed up by lack of vessels, as in 1919.

On the whole the outlook is for a steady summer market for producers of high-volatile coal on the Atlantic seaboard, with a distinct possibility that by autumn the export demand will assume large proportions.

Acid-Resisting Alloys for Use in Mine Water*

Analyses of Three Filtered Mine Waters—Montour No. 1 Water Contains Much Chlorine—Metals and Alloys That Will and Will Not Resist Corrosion—One Metal Gains in Weight—Some Lose by Pitting

By George M. Enos†
Pittsburgh, Pa.

WATER from coal mines frequently is acid, and by corroding pumps and pump parts, pipe lines and other mining equipment causes much trouble. Trouble of like kind is experienced also in metal mines, but to a smaller extent. Data and discussion on the corrosion of a large group of metals and alloys in the acid water from coal mines therefore should be of much value to mine operators and manufacturers of mining equipment.

The water from coal mines is rendered acid by the presence of free sulphuric acid. Usually associated with that acid are considerable quantities of the sulphates of iron and aluminum and smaller quantities of the sulphates of calcium, magnesium, sodium and potassium. Silica and chlorides generally are present. The ferrous and ferric sulphates and the free sulphuric acid found in mine water result from the action of air and water on the iron pyrite (FeS_2) and marcasite (white iron pyrite) with which the coal is associated.

The methods of determining the free and total acidity of the water have been described by Selvig[1] and Ratliff. Free acidity is defined as that due to the presence of free sulphuric acid. Total acidity is the acidity due to acid of that character plus the sulphates of iron and aluminum. Free acid may be present in any quantity from a trace to several thousand parts per million, and as much as 18,000 parts per million have been reported. Total acidity varies between wide limits but usually will be between 2,000 and 15,000 parts per million.

It is beyond the scope of this paper to review the extensive literature regarding corrosion or to discuss any of the theories regarding the manner in which it takes place. It may be well, however, to note some of the common ways in which mining equipment fails as the result of corroding processes. Unless protected, pipe lines of cast iron, wrought iron or steel are corroded rapidly by acid mine water.

Pipe May Corrode Away or Fail by Pitting

The failure may result from pitting or from a gradual wearing away or rusting of the pipe. A common point of failure is at a joint. In order to reduce the replacement of pipes to a minimum most companies operating mines having acid waters use wood-lined pipes. Lead- or porcelain-lined pipes or all-wood pipes having a bituminous coating also are used, but not so extensively as wood-lined pipes.

There are disadvantages in the use of any of these materials: (1) In order to carry any given volume of water the iron pipe must have a much larger outside diameter if it is to be wood-lined. (2) All-wood pipes do not have the required mechanical strength, and if the wires that bind the staves of the pipe together are corroded through, the section bursts and is useless.

Note—Headpiece shows boxes at Calumet mine for testing effect of mine water in corroding metals and alloys.

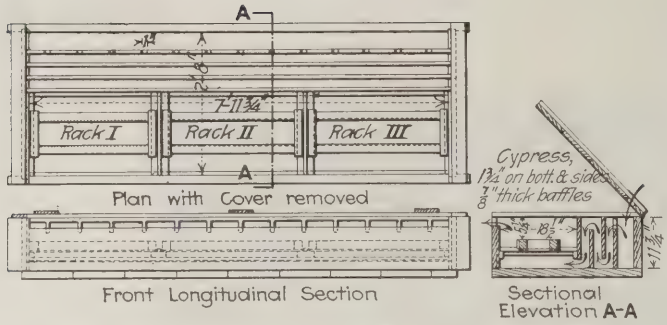

FIG. 1—BOXES IN WHICH METALS WERE TESTED

Metals were set in racks and mine water was passed through the boxes. The samples were only 2 x 6 in. and 16 gage where rolled materials and ¼ in. where cast.

(3) Lead- or porcelain-lined pipes are likely to cause trouble at the joints. The kind of pipe that should be used in acid mine water has not been determined beyond question, but so far the wood-lined pipe has been that most generally used.

The brasses or bronzes and the cast iron used in pump parts corrode fairly rapidly when exposed to the action of acid water. The valve seat, chamber, pump rod and other parts are subjected to the action of acid water flowing at a considerable velocity. It is fairly common practice to babbitt such parts as the chamber and piston, for babbitt resists the action of the water fairly well, although it is soft and abrades easily. In many mines it is not uncommon to have to change pump parts every month or six weeks, this renewal adding greatly to the pumping charge.

Less loss is caused by the corrosion of other equipment. Nevertheless it is important. Track frequently has to be replaced if exposed to the corroding action of acid water. A shovel may be ruined even if exposed to acid water for as short a time as over night.

Neutralization Underground Inexpedient

The question arises, Why cannot water be neutralized, thus saving the expense of frequent replacements of pump parts and pipe lines? Neutralization is practicable only above ground and here only after the water has already been handled by the pumping equipment. If it is necessary to use the water in the power plant, or if the products of neutralization—iron oxides—have a ready market the water can be neutralized with profit. Acid water cannot be neutralized profitably underground owing to the expense involved, not only in excavating the large sumps necessary for this purpose but also in lowering the lime rock, in filtering the effluent and in hoisting the resultant precipitate.

The U. S. Bureau of Mines, in co-operation with the industries, the American Society for Testing Materials,[2] and the Carnegie Institute of Technology,[3] has conducted several investigations into the corrosion of metals and alloys in acid mine water. In the tests already reported it was decided to test the metals and alloys as nearly as possible under service conditions—that is, to immerse the specimens in flowing mine water at the mines.

In the tests made in co-operation with the American Society for Testing Materials[2] test pieces of industrial grades of iron and steel, after weighing, were placed in racks, in suitable test boxes, and water from the mine was allowed to flow through the boxes at a carefully regulated rate. The test pieces measured 2 x 6 in., both 16- and 22-gage materials being subjected to the acid water. The pieces were frequently inspected and careful analyses of the water were made in the course of the test, which was made at the Calumet coal mine of the H. C. Frick Coke Co., Calumet, Pa.

In the second series of tests, made in co-operation with the Carnegie Institute of Technology, specimens of both ferrous and non-ferrous metals and alloys were employed. The non-ferrous alloys included brasses, bronzes, cupro-nickels, nickel-silvers and aluminum alloys. The ferrous alloys included only high-silicon cast irons, high-chromium steel and nickel-chromium-silicon steels. Nickel, copper, iron and aluminum also were included.

The test boxes were of an entirely different design from those in the first test, and the pieces tested were, for rolled materials, 2 x 6 in. and of 16-gage, and, for cast materials, 2 x 6 x ¼-in. The tests were conducted

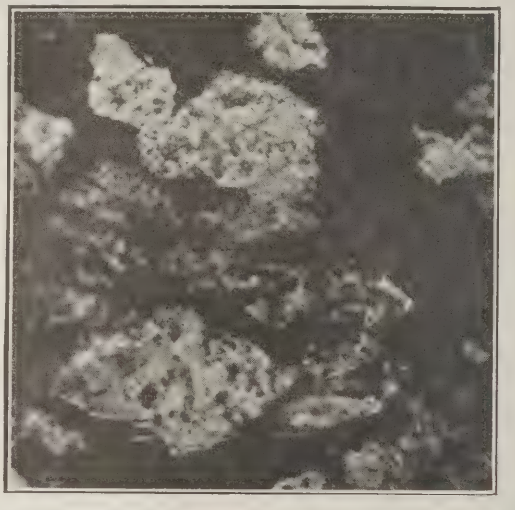

FIG. 2—CORRODED EDGE OF NAVAL BRASS SAMPLE

This alloy consists of copper, 60.40 per cent; zinc, 38.83 per cent; tin, 0.77 per cent. The light colored areas are what are known as Alpha crystals and they are relatively uncorroded. The surface is etched with $NH_4OH + H_2O_2$. Magnification 500 diameters.

at three mines in the western Pennsylvania coal region—namely, Montour No. 1 mine of the Pittsburgh Coal Co., at Southview, Washington County; Edna No. 2 mine of the Hillman Coal & Coke Co., at Wendel, Westmoreland County, and Calumet mine of the H. C. Frick Coke Co., at Calumet, Westmoreland County.

The weighed and measured pieces were totally immersed as in the previous test, the flow of water was carefully regulated and recorded, and inspections and analyses of mine waters were made at regular intervals.

In both series of tests the specimens were considered to have failed if the test piece had been corroded through or if the edge had been corroded to a depth of ¼ in. When the pieces failed they were removed either during the course of the test or at its conclusion. In either case they were cleaned and weighed, and the loss in weight was recorded. The headpiece of the article shows the arrangement of the boxes for the second test at the Calumet mine, and Fig. 1 shows the manner in which the boxes were constructed. Typical analyses of the mine waters from the three mines in which tests were made are given in Table I.

The first tests made at the Calumet mine showed that all the ordinary grades of iron and steel corroded

TABLE I—TYPICAL ANALYSES OF FILTERED MINE WATERS

Constituent	Montour No. 1 Parts per Million (a)	Edna No. 2 Parts per Million (a)	Calumet Parts per Million (a)
SiO_2 (Silica)	160	129	67
Fe ++ (Ferrous iron)	1,216	516	11
Fe +++ (Ferric iron)	56	1,303	213
Al (Aluminum)	1,434	1,225	236
Ca (Calcium)	415	307	164
Mg (Magnesium)	9	122	191
K (Potassium)	373	332	0
Na (Sodium)	1,316	512	61
Cl (Chlorine)	590	37	17
SO_4 (Sulphate radicle)	11,898	11,750	2,229
Suspended matter (on unfiltered water) dried at 105deg. C.	26	19	43
Free acid (b) due to free sulphuric acid	1,200	1,940	340
Acidity (b) due to free sulphuric acid plus sulphates of iron and aluminum	11,070	13,280	2,950

(a) To convert parts per million to grains per U. S. gallon, multiply by 0.0583.
(b) Free acid and total acidity are reported in parts per million in terms of sulphuric acid.

rapidly, and the corrosion losses did not show any materials to be remarkedly superior to the others in resisting the action of acid mine water.

In the second tests the pieces showed a different loss in weight in each of the three mines, as, indeed, would be expected, although the relative order of loss was the same in nearly every case. In the water from the Edna No. 2 mine the losses were greatest. Table II gives the designation, composition and a number which expresses the relative loss in weight of the pieces exposed to the action of Edna No. 2 mine water. This number is based on the daily loss in weight expressed in milligrams per square centimeter of exposed surface.[4] The analyses of the metals in Table II are those given by the co-operating companies wherever they are marked with the notation (a).

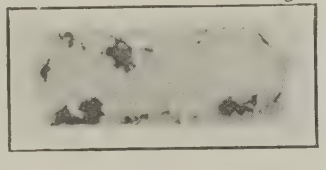

FIG. 3—CAST MANGANESE-ALUMINUM ALLOY

Shows deep pitting. Alloy consists of manganese, 1.81 per cent and aluminum. Unetched; magnification two diameters.

It was found that none of the brasses tested would resist the action of the acid mine water. Fig. 2 shows the corrosion edge of a brass of the Muntz metal type. The manganese brasses have a lower loss number, but on account of the rapid formation of a brittle copper-rich coating, they probably are but little better than ordinary brasses for resisting attack by mine water.

As bronzes have been used so extensively in pump parts, their losses from corrosion are of particular interest. It will be noted that of seven typical bronzes, five have a relatively low loss number. As physical properties may be the determining factor in choosing material for pump parts, it is not possible to say which is the best bronze to use in such cases, but it would seem that from the corrosion viewpoint the leaded bronzes are better adapted for such parts.

The cupro-nickels and nickel-silvers all show relatively high losses, and cannot be considered as having much value for use in acid mine water. Aluminum and aluminum alloys have a low corrosion loss number, but are of no value in acid mine water on account of the extreme rapidity with which they pit and the depth of the pitting. An example of pitting in a cast manganese-aluminum alloy is shown in Fig. 3.

[4]When 0 is used to denote the relative loss, it is understood to mean a corrosion loss of less than 0.5 mg. per square centimeter per day. The exact average loss figures in mg. per square centimeter per day for the Edna No. 2 mine are: High-silicon cast iron B, 0.00374; rolled rustless steel A, 0.00015; rolled rustless steel B, 0.00074; rolled high-chromium steel, 0.00030; rolled nickel, 0.00299, and rolled nichrome, 0.01812.

FIG. 4—CORROSION EDGE OF HIGH-SILICON CAST IRON A

Alloy consists of silicon, 14.5 per cent; carbon, 1.45 per cent; iron and minor impurities, the remainder. Surface is etched with $HNO_3 + HF$. Magnification 300 diameters.

There is a marked difference in the corrosion loss numbers of the high-silicon cast irons tested, which probably is due to the difference in the methods of melting and the difference in carbon content. Fig. 4 shows the corrosion edge of the high-silicon cast iron *A*.

The high-chromium steel and the chromium-nickel-silicon steels have a very small corrosion loss, and it would seem that for mining equipment which could be made of steel, either of these two materials could be used.

Pure nickel shows a very small loss in the Edna No. 2 mine water, but the loss was considerable in the other mine waters in which tests were made. Nichrome had a very small loss in all the waters. The group of copper-lead alloys had neither a high nor low loss number, as did monel metal and for certain purposes these alloys might find considerable use in acid mine water. A peculiar feature in connection with a 96-per cent lead alloy which was tested was the fact that it actually gained in weight during the tests, but as the surface was blistered and the ends cracked on test pieces it cannot be recommended for use in mine water.

An extensive discussion of all the phenomena observed cannot be given here, but the foregoing should be of service in making selections of metals and alloys for use in mining equipment which is to be exposed to the action of acid water.

Careful examination was made of all corroded test pieces, and the nature and extent of deposits, coatings, pits, pinholes and other phenomena were noted and are discussed in Bulletin 4.[5] Microscopic examination was

FIG. 5—COATING ON HARD-ROLLED PHOSPHOR BRONZE

Alloy consists of copper, 89.8 per cent; tin, 5.6 per cent; lead, 4.6 per cent; iron, a trace; phosphorus, 0.5 per cent. maximum. Surface is etched with acidic $FeCl_3$. Magnification 200 diameters.

made of the entire series of metals and alloys corroded in the Edna No. 2 mine water, and the results will be published shortly.[6] In order to arrive at an intelligent understanding of corrosion processes, also of the relative value of various metals and alloys, it is necessary to consider not only the data as to loss in weight but also the condition of the test pieces after corrosion, as shown by careful visual and microscopic examination. Deep pitting, for example, may not result in much loss in weight, yet would render the material unfit for use in acid mine water.

In the course of the examinations made coatings were observed on many of the metals and alloys. These coatings may result from the decomposition of the specimen, by deposition from the water or from both causes. Many of the coatings could be easily removed, and it is not possible to say whether they accelerate or retard corrosion. Other coatings were relatively hard and impervious and could properly be designated as protective in nature. Such a coating is shown in Fig. 5.

As a result of the various investigations the following general conclusions may be drawn regarding metals and alloys for use in mine water:

(1) Ordinary industrial grades of iron and steel, brasses, cupro-nickels, nickel-silvers and aluminum and aluminum-alloys will not withstand the action of acid water from coal mines.

(2) A high-silicon cast iron, a high-chromium steel, two chromium-nickel-silicon steels and nichrome were very resistant to the action of acid mine water.

(3) Certain bronzes, copper-lead alloys, nickel and monel metal may be of value for special purposes where it is not desirable to use the materials previously mentioned.

The writer wishes to acknowledge the aid received from A. C. Fieldner, supervising chemist of the Pittsburgh Experiment Station, U. S. Bureau of Mines, and from W. A. Selvig and R. J. Anderson, also of the Pittsburgh station.

Wahlen Micromanometer Accurately Measures Static And Velocity Heads in Mine Ventilation

Will Measure Differences of Pressure to Ten-Thousandth of an Inch of Water Pressure and Even Less—How to Separate Resistance Pressure from Velocity Head—Reliable Coefficients Need to Be Worked Out

By Louis W. Huber*
Urbana, Ill.

RELIABLE indications of air pressure are essential if the effect of turns, contractions, expansions and surface irregularities, such as steel and timber sets, rough ribs and roofs and standing props, in reducing the flow of air are to be measured. Economies that conceivably may be of great importance have not been made owing to the fact that up to the present we have not been able to evaluate with sufficient exactitude the savings that certain improvements in air channels would effect. The question is now being put under careful and scientific investigation, and it has been found that to make the necessary tests the introduction of new apparatus is needful. Here again it will be noted that the necessities of a line of inquiry remote from that of mining have furnished the coal-mining investigator with a valuable tool for the development of his industry.

The Wahlen gage or Illinois micromanometer is, strictly speaking, an alcohol gage for determining differential pressures. It was developed by F. G. Wahlen for the University of Illinois engineering experiment station. The need for such a gage was felt by the staff of that station for use in connection with its researches into warm-air furnaces. A manometer was needed for measuring the pressures associated with low air velocities of from 2 to 7 ft. per second or velocity heads of about 0.0015 to 0.0120 in. of water.

Exceedingly Sensitive to Pressure Changes

What was desired was a measuring device that would offer no frictional resistance to the flow of air, that would be exceedingly sensitive, readily portable and easy to operate. It was felt that a Pitot tube, used in connection with an extremely sensitive gage, would fill all requirements and allow the flow of air to be measured directly. A Chattock† gage was constructed and tested, but, although it was sensitive enough, operating difficulties prohibited its application to the work.

F. G. Wahlen was detailed to this investigation, and he developed a gage so sensitive and accurate that it would measure heads of less than 0.0001 of an inch of water and respond almost simultaneously to the slightest fluctuations in pressure.

The essential features of the Wahlen gage as shown in the illustrations (Figs. 1 and 2) are a rigid base supported by three leveling screws and leveled by means of a right-angle or "cross" spirit level, and two large glass bulbs (*A* and *B*) communicating with one another by means of an inverted U-tube, and supported by the rigid base. The left-hand bulb, *B*, is firmly and rigidly attached to the frame and is always stationary. The right-hand bulb, *A*, is fixed on a carriage which permits it to be moved vertically up and down. This motion is controlled by frictionless guides which eliminate all side motion. The bulb is raised and lowered by a micrometer screw reading to 0.001 of an inch direct, a slight swiveling action in the joints of the hinged connection of the glass tube at *E* admitting of this movement.

Alcohol saturated with kerosene of a specific gravity of 0.8195 and colored with aniline dye to a distinctive red color about half fills the two bulbs and the U-tube. The upper half of the U-tube is filled with a clear mixture of kerosene and ligroin, so apportioned that its specific gravity is about 0.0095 less than that of the alcohol. Ordinary kerosene may be used as the lighter

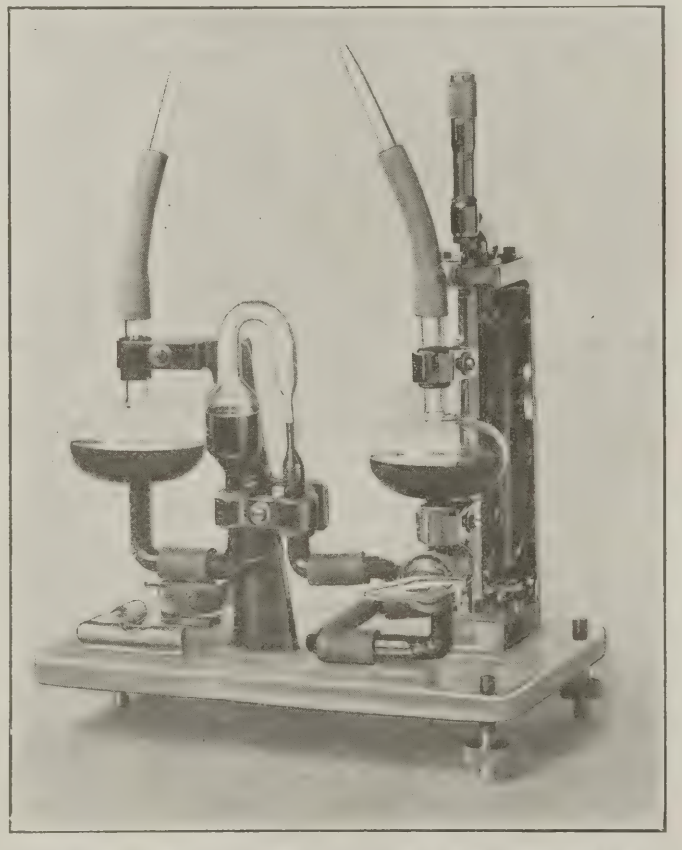

FIG. 1—WAHLEN GAGE OR ILLINOIS MICROMANOMETER
Air is received under different pressures in the two flasks, or bulbs, on either side of the instrument, and this disturbs the level of the fluid so that to keep the level constant it is necessary to raise the right flask. This is done by a micrometer screw the movement of which records that motion. The parts of the connecting tube which appear empty or filled with air contain pure kerosene or more usually a colorless mixture of kerosene and ligroin. The darker liquid in the tube and flasks is alcohol saturated with kerosene and colored with aniline dye. The junction of the two liquids, the level of which is manipulated by the raising of the right-hand flask, is brought to coincidence with an etched line in the constricted part of the tube.

*Graduate assistant in mining research, University of Illinois.

†See "Report on Wind Tunnel Experiments in Aerodynamics," by J. C. Hunsaker and others, page 12 and following pages. Published by the Smithsonian Institution, Washington, D. C., Jan. 15, 1916.

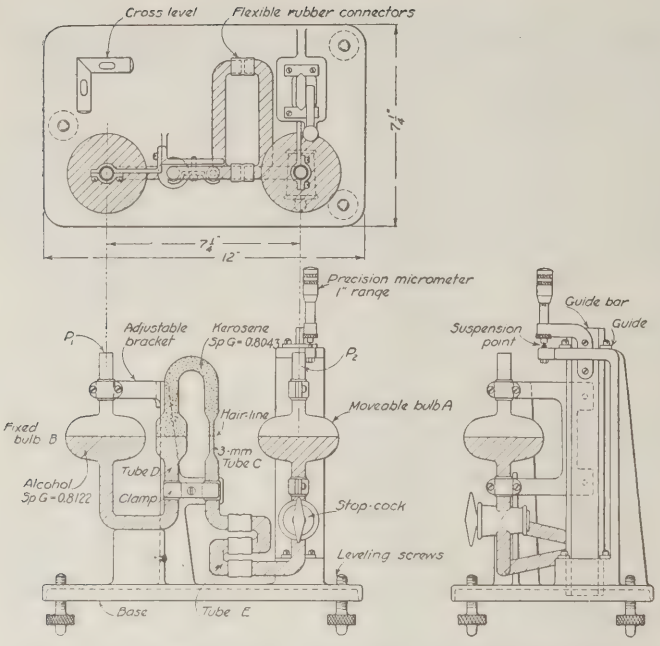

FIG. 2—DIAGRAMMATIC DRAWING OF WAHLEN GAGE

The adjustment of the instrument always is to the hairline in the 3-mm. tube *C*. Raising the right flask, or bulb, *A*, one-thousandth part of an inch moves the liquid in the 3-mm. tube ½₅ of an inch. This large multiplication of the movement of the bulb makes the adjustment of the gage quite delicate and gives a remarkably accurate measurement of the difference of pressure. The adjacent enlargement of the tube at the same level also makes it possible to adjust the instrument with remarkable accuracy.

liquid if the above difference in density is maintained.

It will be observed in the illustration that the right leg of the inverted U-tube is constricted at *C* and the left leg enlarged at *D*. These points are where the alcohol and the kerosene join. The left leg is enlarged so as to provide for maximum sensitiveness. The constriction in the right leg is for the same purpose. A hairline is etched around the middle of the constricted part of the tube.

In making a zero setting with equal pressure on the surfaces of the liquids in each bulb both bulbs are opened to the air so that the pressure in each is equal and the meniscus, or the juncture of the kerosene and alcohol, is brought to the hairline by raising or lowering the right-hand bulb with the micrometer screw. The reading of the micrometer when the meniscus is at the etched reference line is called the zero reading.

Meniscus Always Restored to Etched Line

It is seen then that if bulbs *A* and *B* were connected directly to pressures P_2 and P_1, respectively, and if P_1 were greater than P_2, greater pressure would be exerted on the surface of the liquid in bulb *B* than in bulb *A*; this pressure would tend to depress the liquid in *B*, force the liquid in *D* upward, and the liquid in *C* downward. This would tend to cause the meniscus to descend from the etched reference line, but this tendency can be neutralized by raising bulb *A* and thus causing a "head" of alcohol to work against the pressure tending to move the meniscus.

By means of the micrometer the bulb *A* is raised as high as is necessary to neutralize the pressure difference between P_2 and P_1. The exact distance that the bulb is raised is obtained from the difference between the zero, or initial, reading of the micrometer and the final reading. This means, then, that the difference between pressures P_1 and P_2 is equal to the head of alcohol obtained by raising bulb *A*. The distance the bulb is raised is measured directly to 0.001 of an inch on the micrometer and if necessary it can be measured to 0.0001 of an inch.

Knowing the head in inches of alcohol and knowing the temperature of the alcohol, which is, of course, the temperature of the surrounding air, the specific gravity of the alcohol can be found from a temperature-specific gravity curve and the head or pressure in inches of alcohol can be changed to inches of water, pounds per square foot, pounds per square inch, or whatever is desired. The specific gravity of alcohol varies with the temperature, so a specific gravity-temperature calibration curve is made of the alcohol in the gage each time it is filled. (Fig. 3.) A final zero reading always is taken after using the gage, and the initial zero reading and final zero reading should check within at least 0.001 of an inch.

Before filling, the glassware and rubber tubing of the gage must be chemically clean so that the liquids and particularly the meniscus or juncture of the alcohol and kerosene will rise and fall easily and cleanly. The red, or alcohol, liquid is put in the gage first so that it completely fills the inverted U-tube *C*, all the connections, and about one-third of the bulbs.

Care Used in Filling Micromanometer

A small measuring pipette with a stopcock to govern the flow and a small rubber tubing attached to the end is filled with kerosene. The kerosene is allowed to fill the rubber tubing completely so as to insure the absence of air bubbles, and the tubing is inserted down through bulb *B*, around the bend below *B*, and up through leg *D* of the inverted U-tube. The stopcock below bulb *A* is left open so as to permit equal displacement in bulbs *A* and *B*, and the kerosene, or colorless liquid, is allowed to ascend into the inverted U-tube and displace the alcohol. Enough kerosene is admitted (controlled by the stopcock in the glass pipette) to displace the alcohol and bring the two juncture points of the liquid within the constricted tube *C* and the enlarged tube *D*.

The specific gravity of the alcohol is obtained at several different temperatures by means of a Westphal specific-gravity balance, and a calibration curve, con-

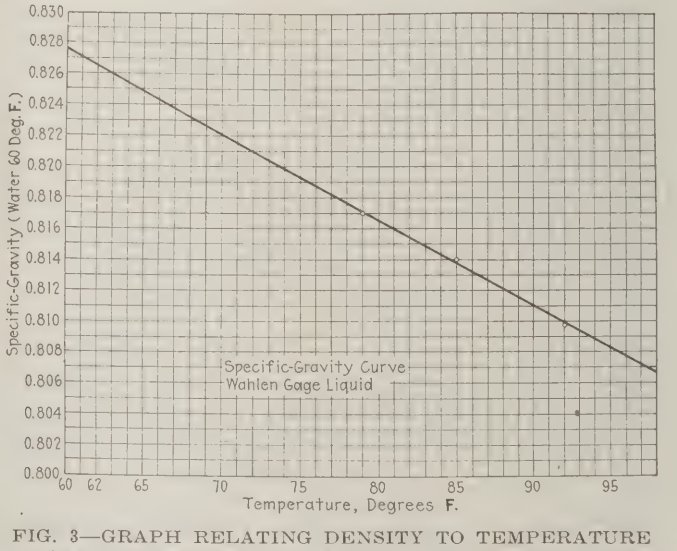

FIG. 3—GRAPH RELATING DENSITY TO TEMPERATURE

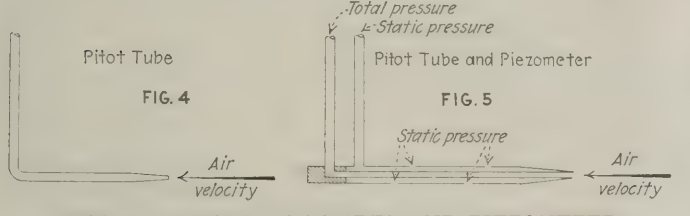

It has been determined that 0.8195 is a good working specific gravity for the mixture of alcohol and kerosene, but whatever it is its specific gravity must be known for every temperature likely to be encountered. This graph, starting at 60 deg. and ending at 100 deg., is adequate for intake temperatures, though only in places for those in the real workings.

necting specific gravity with temperature, Fig. 3, is drawn for the range in temperature under which the gage is likely to be operated.

A thousandth of an inch movement of the micrometer screw moves the meniscus about a sixteenth of an inch. This movement of the meniscus, however, can be adjusted to be greater or less by adjusting the difference in the specific gravities of the two liquids to be greater or less than 0.0085. This density, however, has been found to be about the "happy medium" for ordinary work.

In operating the gage after the bulbs are connected to the differential pressures P_1 and P_2, the stopcock below A is opened slightly until the direction of the movement of the meniscus is observed; it is then closed and bulb A raised or lowered to neutralize the pressure tending to move the meniscus; this is repeated until the pressures are balanced and the meniscus is stationary and at the etched reference line. In this way, by careful and delicate manipulation, the meniscus is never permitted to move out of the constricted part of the tube C.

It is evident then that, as there is no movement of

FIGS. 4 AND 5—PITOT TUBES AND PIEZOMETER

The pitot tube is affected by both velocity and static head, but with the piezometer attachment and the Wahlen gage the total head can be partly balanced by the static head and the difference will be the velocity head. The static head is obtained by openings the edges of which lie in the plane of the current and not at right angles to it.

the liquids, no corrections need be made for capillarity, viscosity, variations in the bore of the tubes, or conditions of the glass surfaces. The sensitiveness of the gage depends upon the relation between the areas of the cross-section of the large bulbs and the cross-section of the constricted tube, the viscosity characteristics of the two liquids, the small difference in specific gravity, and upon the fact that the constricted part of the U-tube is short. Other connections are large and free. The micrometer used is a standard machinists' micrometer with three-quarters of an inch to an inch measuring range.

The gage was developed primarily for measuring low air velocities with a Pitot tube, and it can well be used for this down in the mine, for no matter how carefully and accurately an anemometer traverse be made of a mine entry the results are not trustworthy as there are friction losses (especially if an anemometer cannot be rested on a firm base), mechanical defects in the anemometer, and quick changing puffs of air in the main flow due to innumerable projections and constantly changing eddy currents.

An anemometer cannot be calibrated so as to correct these defects and irregularities. When velocity readings are made with a sensitive gage and Pitot tube the readings are reliable, for by this system velocity pressure, and hence velocity, is measured direct, and the only requirements are that the Pitot tube be held out firmly so as to be stationary and meet the air flow squarely.

However, a plain Pitot tube such as is shown in Fig. 4 would measure not only velocity pressure but the static pressure as well. Air flowing in restricted passageways such as air duct, galvanized pipe or airways down in the mine is under three distinct pressures: the velocity pressure, static pressure, and dynamic pressure. The velocity pressure is that pressure necessary to change a quantity of air from a state of rest to a state of motion. It is, then, the pressure or head necessary to accelerate a mass of air from a state of rest to the final velocity attained.

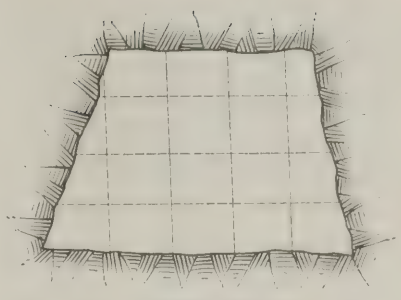

FIG. 6—MANNER OF DIVIDING AREA FOR PRESSURE SURVEY

Measurement of the pressure can be taken at the center of each square or at the intersections of the lines shown. In this way an average result for the airway may be obtained.

The static pressure, or head—also termed the frictional, or resistance, pressure, or maintained resistance—is the pressure necessary to overcome the resistance offered to flow. It is in reality the pressure exerted against the sides of the airway that the air is flowing in and is measured as such with the ordinary pressure gage. The dynamic or total pressure—also termed the impact pressure—is the sum of the pressures required to overcome resistance to flow and create the velocity of discharge. It is equal to the sum of the static and velocity pressures.

Modifying Pitot Tube to Get Static Head

Obviously then the pressure recorded by the Pitot tube in Fig. 4 would be the total pressure. We desire to measure velocity pressure, and can do so because velocity pressure equals total pressure minus static pressure. By measuring the difference between total pressure and static pressure we can measure velocity pressure alone. This is accomplished by attaching the two separate bulbs of our differential gage to the total pressure and to the static pressure and measuring the differential pressure, which is the velocity pressure or head. This is accomplished by means of a Pitot tube as shown in Fig. 5.

The piezometer and Pitot tube are combined in one tube in the above illustration. This is the standard tube which the American Blower Co. uses for fan testing. Static pressures are exerted through the small holes in the side of the outer tube whereas both velocity and static pressures are exerted through the center or Pitot tube. These tubes are completely separated from each other so that different pressures are exerted in each one, and the difference between them is measured.

By means of such a tube and a Wahlen gage a careful and accurate traverse of a mine entry can be made in a comparatively short time and the different velocity pressures or heads accurately determined. The best sort of a traverse is made by dividing the entry area into a number of squares (Fig. 6) and taking a reading either in the center of each square or at the cross points of the division lines and averaging the resulting heads.

The formula for getting velocity in feet from head in inches of water is derived from the formula for the

velocity of falling bodies, $v^2 = 2gh_x$. When g is the acceleration of gravity in feet per second per second, h_x is the head, or height in feet, of the flowing medium and v is the velocity of the flowing medium in feet per second. We cannot measure the head or height of air column inducing flow directly in feet of air, so we measure and express it in inches of water.

If h_x = head, or height in feet of the flowing medium, or air, and h_v = head in inches of water:

$h_x d = \frac{h_v k}{12}$, where d = density of air, lb. per cu.ft. and k = density of water, lb. per cu.ft.; 62.4 lb. at 70 deg. F. Then, $12\,dh_x = h_v k$

$$h_x = \frac{h_v k}{12\,d} = \frac{v^2}{2g}$$

$$v^2 = \frac{2gh_v k}{12\,d}\ ;\ v = \sqrt{\frac{2gh_v k}{12\,d}}$$

$$v \text{ in ft. per sec.} = 18.27\sqrt{\frac{h_v}{d}}$$

h_v is measured directly in inches of water and d can

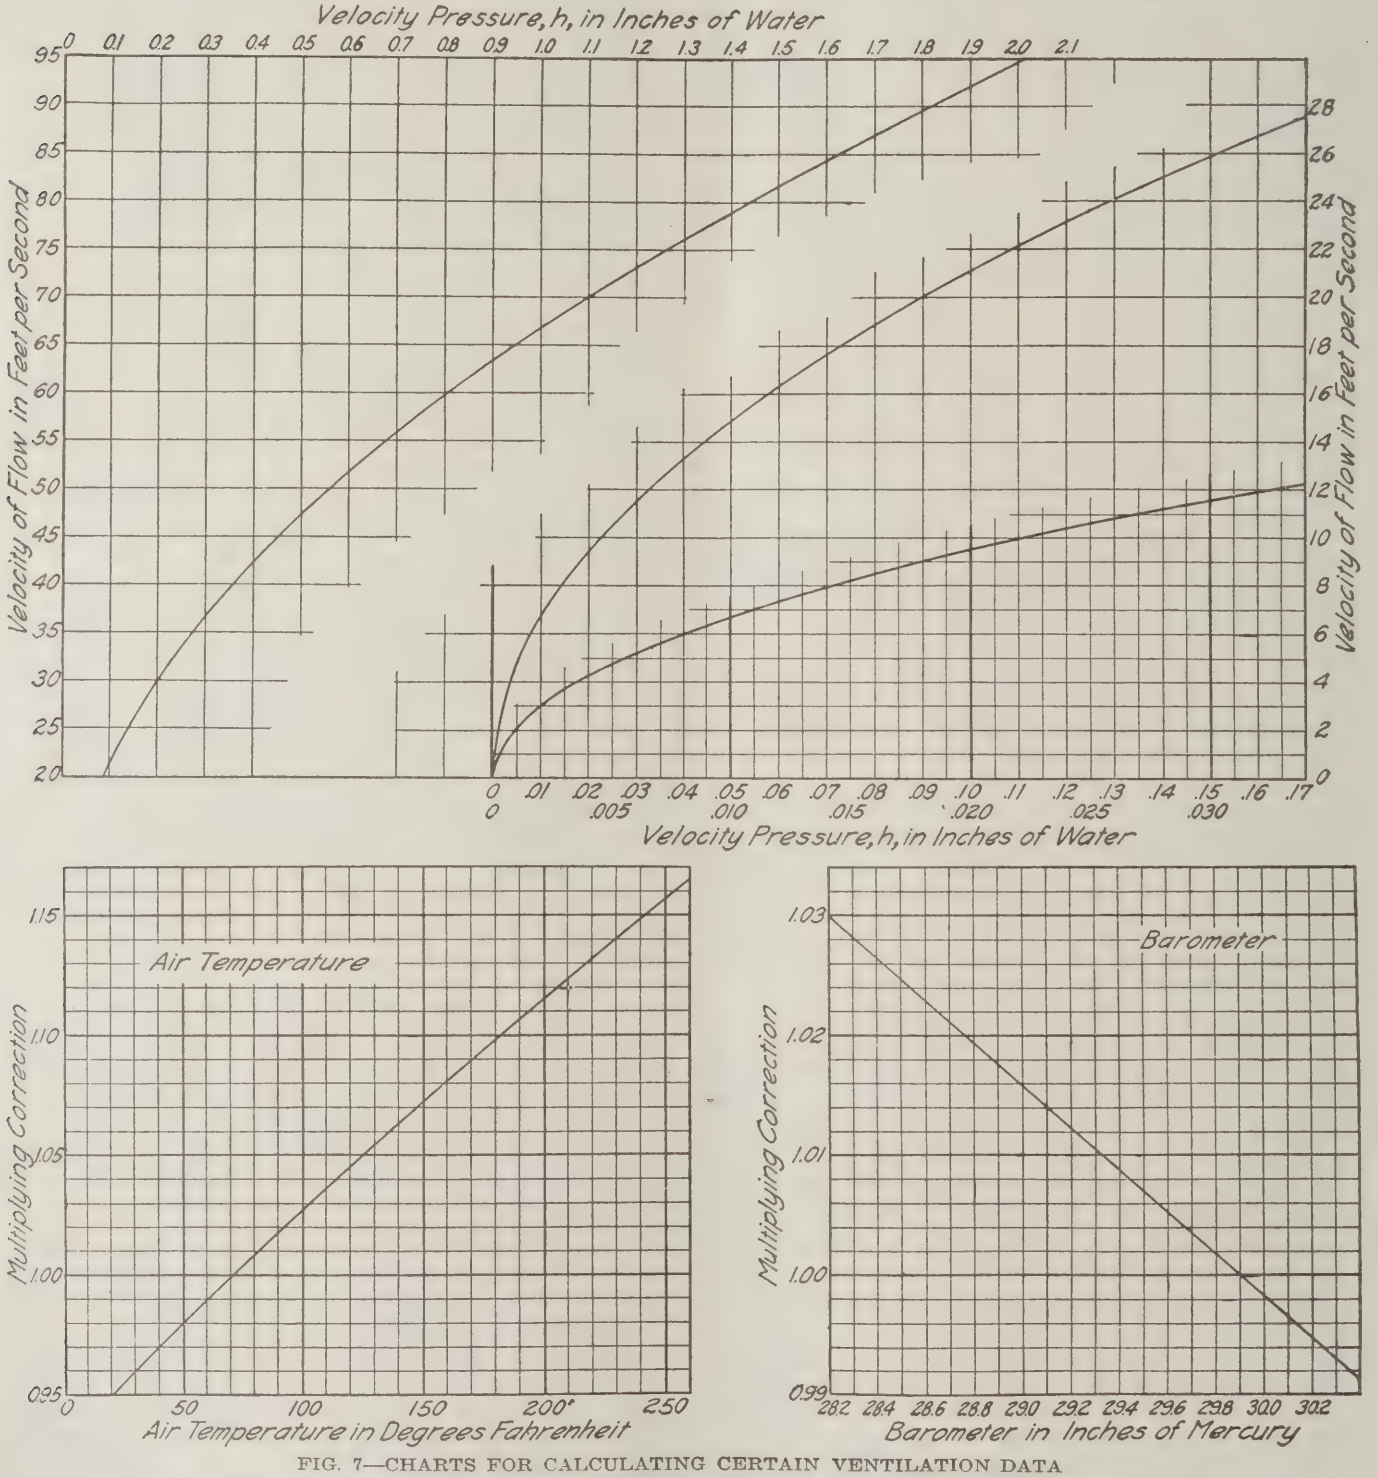

FIG. 7—CHARTS FOR CALCULATING CERTAIN VENTILATION DATA

The upper curves give velocities corresponding to velocity heads in inches of water, but these have to be corrected both for air temperatures and barometer readings. The gage-water density correction is negligible. $v = gkh/6d$ when g = 32.17; h = velocity pressure in inches of water; k = water density at 70 deg. F. = 62.4 lb. per cubic foot; d = air density at 70 deg. F. and 29.92 in. of mercury = 0.0749 lb. per cubic foot.

be calculated for any temperature and barometric pressure by means of the formula

$$d = \frac{1.325\,B}{T}.$$

B = barometric pressure in inches of mercury.
T = absolute temperature in degrees Fahrenheit.

This latter equation is derived from our formula for a perfect gas, namely $PV = MRT$. Air acts as such a gas and obeys this law within normal conditions of temperature and pressure.

P = absolute pressure in pounds per square foot.
V = volume in cubic feet.
M = weight of air in pounds = 1.
T = absolute temperature in degrees Fahrenheit.
R = 53.37, the constant for air.

$$PV = MRT \quad d = \frac{1}{V} = \frac{M}{V} = \frac{P}{RT}$$

$$d = \frac{144 \times 0.491 \times B}{53.37 \times T}$$

$$= \frac{1.325\,B}{T}$$

Much calculation, necessary to convert from inches of water to feet per second, can be avoided by means of the curves shown in Fig. 7. The results obtained from these graphs are accurate enough for all practical purposes.

The Wahlen gage is a precise and valuable instrument for measuring air velocities, but it has further values of some consequence in mine ventilation. The coefficient of friction for shaft lining and for sections of entry can be easily and quickly determined by means of the Wahlen gage and the static-pressure boxes developed at the University of Illinois mining engineering experiment station.

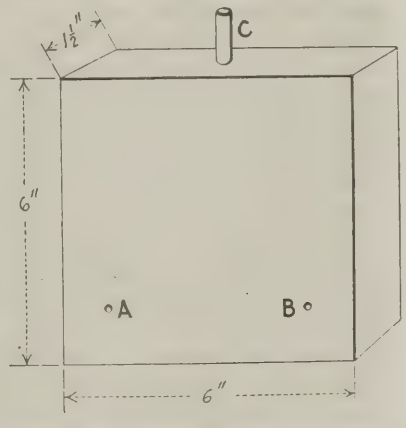

FIG. 8—STATIC-PRESSURE BOX

With the 1½-in. side of this empty airtight box facing the ventilating current the air has no easy task to find the minute holes *A* and *B*, and consequently the air in the box is subject to none of the pressure that is due to the velocity of the air in the passageway. The static pressure of the airway is all that affects the pressure in the box. That pressure is communicated through pipe *C* and thereby to one of the bulbs in the Wahlen gage.

These static-pressure boxes (Fig. 8) are empty galvanized-iron boxes, 1½x6x6 in., completely airtight, except for two No. 60 drillholes in each of the two broad sides and a hole in the top. Around this hole in the top a short piece of brass tube ¼ in. in diameter is soldered. When the box is set down in the mine entry with its narrow side facing toward the wind, only static pressure is transmitted through the small No. 60 drillholes in the sides, thence through the brass tubing acting as a nipple on the top, and thence through rubber or other flexible tubing to the gage, where it is measured. The distance through which the pressures are transmitted is immaterial, providing the pipe or tube through which they are transmitted is airtight and providing enough time is allowed for the pressure to become constant through the entire pipe or tube.

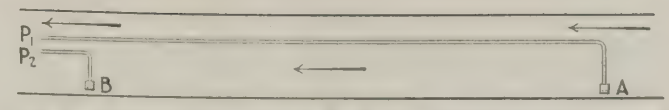

FIG. 9—METHOD OF USING BOX TO DETERMINE CHANGE OF STATIC PRESSURE IN ENTRY

The pressure P_1 from box *A* is taken to one bulb of the Wahlen gage and the pressure P_2 from box *B* is taken to another. The difference in pressure determines the loss of head resulting from the resistance of the airway.

In Fig. 9 the pressure boxes at *A* and *B* record the static pressures, P_1 and P_2, that exist at those points. These pressures can be transmitted through the tubing to a convenient spot where the Wahlen gage is located, and the difference between them measured. The difference between P_1 and P_2 represents the static pressure loss or the pressure necessary to force the quantity of air flowing (this quantity must also be measured) from point *A* to *B*. This is the pressure necessary to overcome the resistance offered to this quantity of air and is the part of the total water gage for which this section of entry *A* to *B* is responsible.

With two static pressure boxes, enough tubing, and a Wahlen gage an observer can go throughout the air courses of a mine and find the main causes of loss of pressure, and hence the power losses. The resistances offered by and the pressure lost in overcoming the resistance of each obstruction, bend, section of irregular and jagged entry, section of heavily timbered entry, approach and retreat to and from overcasts, sharp turn, and sump occurring in the air courses can be segregated and the mine resistance thoroughly investigated.

Are Bends and Obstructions Bad as Stated?

If the exact pressure and power loss caused by some obstruction or irregularity in the ventilating system is known, it is easy to calculate whether or not it would pay to remedy the obstruction. At present the mining engineering experiment station of the University of Illinois, College of Engineering, is investigating the power losses caused by sharp bends and sumps at the bottoms of airshafts.

In a paper read before the West Virginia Coal Mining Institute at its summer meeting in 1910, Thomas W. Fitch, Jr., stated that: "The resistance offered by turns can be disregarded for low velocities, but where the velocities are high, the loss of pressure becomes serious. Where air is forced around a right-angled turn, with the corners square, the pressure loss usually is assumed to be double the velocity head. For example, if air is traveling in an airway at a velocity of 1,000 ft. per minute, its velocity head is 0.06 in. water gage, and the loss due to a right-angle turn would be 0.12. Where a curve is used this will be greatly reduced."

Mr. Fitch's conclusions were not based on actual experiment in the mine but rather on similar experiments with piping systems. With the Wahlen gage and static-pressure boxes sufficient data can be collected showing at different velocities the resistance of all sorts of turns, expansions and contractions which Mr. Fitch asserts are serious sources of pressure losses when the velocity is high. From these a reference curve or table can be constructed.

By referring to such a curve or table for bends and irregularities and using a dependable coefficient of friction for stretches of entry, the mine resistance and

operating water gage could be estimated much more closely than it is now by means of the coefficient of friction alone.

The coefficient of friction to which reference most frequently is made is that advanced by Atkinson and is 0.0000000217. This is the resistance, in pounds, offered by 1 sq.ft. of rubbing surface to air flowing at the rate of 1 ft. per minute. This coefficient will suffice for rough, crooked, irregular and timbered air passageways, but is much too high for average airways. Much work must yet be done before good standard and reliable coefficients for different conditions are established, for from Atkinson's time to the present the general coefficient for average airways has been given values of from 0.000000001872 to 0.0000000219.

Operators and superintendents are coming to realize more and more that power losses in the ventilation system are much more serious than they seem to be, because the ventilating fan and system is in operation 24 hours a day seven days a week. If we consider a small mine producing 1,000 tons of coal per day as requiring 50,000 cu.ft. of air per minute; in a week the mine will produce 6,000 tons of coal, but the fan, working continuously and blowing air at the rate of 50,000 cu.ft. per minute through the mine, will have handled

$$\frac{50{,}000 \times 0.075 \times 60 \times 24 \times 7}{2{,}000}$$ or 18,900 tons of air.

This means that for every ton of coal that was hoisted 3.15 tons of air was forced through the mine.

The Wahlen gage is not as yet a practical gage for everyday use, because it is delicate and heavy and must be manipulated carefully in order that trustworthy results can be obtained. It is an extremely valuable instrument in the hands of one who has become accustomed to its manipulation while making accurate ventilation determinations or while making researches into the flow of air and ventilation.

To Discuss Equipment Problems in Forum At Mining Congress Convention

THE national expositions of mines and mine equipment have become a permanent and important feature of the annual conventions of the American Mining Congress, which are the recognized meeting place for mining men from all parts of the United States. At the two previous expositions the attendance was made up largely of mine executives and high operating officials. The attendance of these men have been of great value but naturally the exposition, with its comprehensive display of every type of mechanical equipment entering into mine production, is of special interest to the operating men, who have daily problems to solve in connection with the handling of particular phases of mechanical equipment.

As a matter of fact the objective of these expositions has been and is primarily to furnish the mine operator with an opportunity of studying and comparing all of the different types of equipment in order that through such comparison he may be able to solve his equipment problems and to obtain the exact type of equipment particularly adapted to the working conditions in his mine.

The value of this opportunity can hardly be overestimated, says E. C. Porter, convention manager, but the greatest benefits will never be obtained until the mine owner and mine executive makes it a point to see that the different operating men in his mines dealing with electrical equipment, transportation problems, the handling of explosives, etc., are sent once a year to these expositions at company's expense to study and report and thereby be in a position to use the knowledge thus gained as a basis of saving money and of lowering costs through intelligent purchase of the right type of mining machinery and mine equipment.

In order to give operating men an opportunity of discussing in an informal and practical way the day-by-day equipment problems which are met in mining enterprises, the convention and exposition management has arranged this year as a special feature of the Milwaukee meeting, Sept. 24-29, a series of group conferences between the representatives of the exhibitors and the operating men which has been designated the "Open Forum."

Will Educate Coal-Mine Operatives

PENNSYLVANIA STATE COLLEGE, through its president, Dr. John H. Thomas, has outlined a plan for helping ambitious young men who are engaged in mining to learn more of the technical as well as the practical side of the work.

State College already has a course in mining engineering but Dr. Thomas plans a short course in practical mining where young men may receive instruction either personally or by mail. The course is designed to teach how to operate pumps, fans, mine cutters, fan systems, electrical apparatus and other machinery with which mines are now equipped. This is not the work of the mining engineer, but the work incident thereto pays well nevertheless and operators and mining companies are finding it increasingly difficult to get competent men to fill these positions.

Heretofore operators could get skilled men for such jobs only by training them at the mines. Men with the proper training and ability are paid from $200 to $400 per month, and the jobs are well worth while to the young men who equip themselves for that purpose. This work has been conducted in a haphazard manner in the past and it is the opinion of Dr. Thomas that a school such as is planned can do much to bring about better results, especially in the central Pennsylvania bituminous field.

State College is situated near a field that mines one-twelfth of all the coal produced in the United States. The school will be designed distinctly for coal miners. No technical or educational attainments will be required for entrance into the school save a reasonable, natural aptitude and the ability to read and write. Thus there will be no barriers to keep out ambitious young men.

Dr. Thomas is of the opinion that such a course would tend to keep young men in the business and increase their earnings. In connection with the course, camps of instruction would be established at central locations, near a well-equipped mine, where practical instruction could be given.

MINERS APPEAR CONFIDENT, for some reason, that the Government could run the coal mines better than it ran the railroads.—*Washington Star.*

WHAT WE NEED just now is not the output of the best minds so much as the output of the best mines.—*New York Tribune.*

Tank for Cleaning, Classifying and Thickening, in One Operation, Fine Anthracite or Bituminous Coal

Water Near Top of Tank Drawn Off by Centrifugal Pump and Fed in Slowly Revolving Jets to Bottom Stratum, Where It Loosens Mixture, Permitting Coal to Float to Base of Clear Zone

By John F. Hardecker
Brooklawn, N. J.

TO THE coal industry, breaker, or washery, slush is at present an ever-growing nuisance. In fact in most cases it represents an actual monetary loss to the operator. It is essential that this, as indeed every other waste, should be eliminated. Breaker water in itself is in many instances a source of no inconsiderable expense. To recover most of the coal in the slush and clarify the water so that it may be used again and to do both of these things economically and practically would be an advantage to everybody. If this could be done the apparatus would not only save coal but render the water from the breaker available for re-use. Such a device, therefore, would be to the operator a source of additional output and profit.

Before examining the method to be advocated it might be well to review the means by which efforts are being made in some few places to eliminate this waste. These involve the use of three machines. A classifier is used to remove from the breaker slush all coarse granular matter, but that, unfortunately, includes all the impurities. An effluent much diluted, but carrying nevertheless much coal and impurity, is discharged from the classifier. This discharge is then treated in a thickener, which thickens it to about 50 per cent moisture. Even this is not a perfect action, as much fine coal escapes with the water that leaves the thickener. The product of the classifier contains such a large quantity of impurities that it is necessary to treat it in a concentrator, which at best leaves from 8 to 12 per cent of impurities in the final product.

Cleans, Sizes and Thickens Product

The machine to be described does the work of all three machines, acting at once as a thickener, classifier and concentrator. Furthermore, it will catch all of the extremely fine and all the coarse coal, separate the impurities, and leave the coal product in a thickened state ready for distribution.

The machine is illustrated by a sectional view in Fig. 1, an exterior view being shown in Fig. 2. It is intended for washing and purifying the finer grades of coal direct from the crusher or breaker, separating them in particles of a size suitable for the grade they are to occupy, and collecting and thickening the extreme fines, which are ordinarily washed to waste. The entire operation is performed in one passage through the machine and is applicable to both bituminous coal and anthracite. The machines can be made of any size and for any capacity. They have been made to deliver 500 tons per day but can be designed to have even greater output.

The machine is so constructed that when filled with a dilute mixture of solids circulation is caused by withdrawing liquid from above through an annular suction conduit, *A* (see Fig. 1), and projecting it toward the bottom from rotating jet nozzles, *B*. These nozzles rotate automatically about a cylindrical base, *C*, being suspended from above by a cylindrical shaft, *D*.

The arms from which the jet nozzles project, *E*, are immersed in the liquid, and due to their relatively slow velocity, scarcely disturb the liquid through which they are passing. The overflow launder takes out all excess water that accumulates in the system as a result of the continuous introduction of slush-laden water. The circulating pump, *F*, has a bypass above it for regulating the volume of circulation and controlling the strength of the current issuing from the rotating nozzles. To aid in the work of classification the tank is constructed with sloping sides. It also has a V-bottom for the better accumulation of the impurities.

The circulating pump withdraws thin liquid from the suction level and forces water through the rotating arms. This water escapes as jets from the revolving nozzles and sweeps through the solids to the bottom of the track. These streams, impinging on the bottom, cause a continuous return movement of water to the suction inlet. This upward flow in the tank extends only to the suction level, *G*, below which all the solids fall and are confined. The space above, termed the "clear zone," is a quiescent settling basin, undisturbed by any action from below.

The jet streams merely loosen the submerged strata and allow the impurities to settle back into place, the coal floating upward. It is a well-known fact that when sand or fragments of impurities heavier than coal are kept in close liquid suspension they will cause the coal, which is of lower specific gravity, to float to the

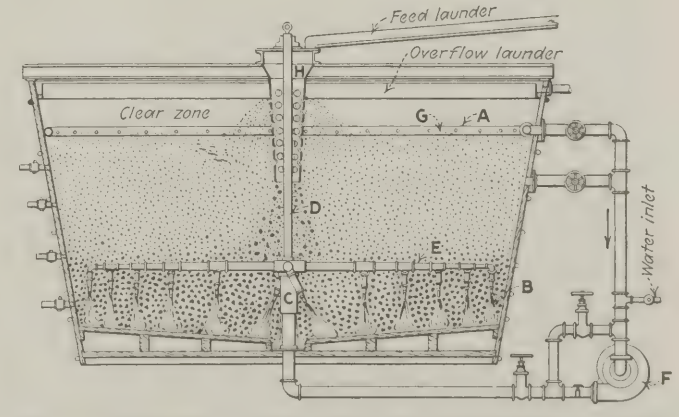

FIG. 1—SECTIONAL VIEW OF TANK THAT WILL CLEAN, SIZE AND PARTLY DEWATER COAL

By this tank the water is so freed from coal and impurities that it can be used over and over again in the washing process. The finer coal rises to the bottom of the clear zone and when removed is in a fairly thick condition. Middling coal may be discharged separately and still further reduced in size by crushing, after which it can be returned to the tank for further purification. The slate, sand or clay particles and the pyrite can be removed by a pipe near the bottom. An overflow launder is used for the discharge of clear water. Concentration and classification take place also as the tank is being fed with slush.

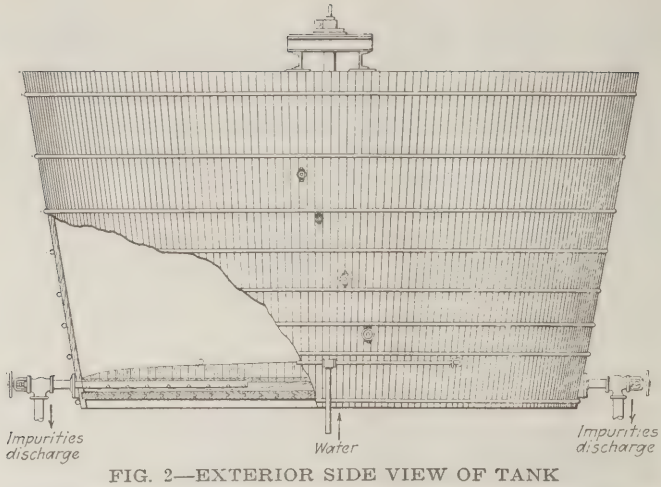

FIG. 2—EXTERIOR SIDE VIEW OF TANK

Note the flaring sides which with the growing decrease in the crowding of particles make the velocity of the water and coal on rising continuously decrease so that both finally come almost to rest, permitting sedimentation of even the purest and smallest of particles and the formation of a zone of clear water near the surface of the fluid in the tank. The impurities are drawn out at the bottom.

surface of the denser medium. To this extent the machine becomes a classifying thickener, which gathers the inflowing solids and stratifies them according to size and quality.

When the solids in the form of finely crushed coal (more or less impure) are introduced into the distributor, *H*, either in the dry or dilute condition, the coarser and heavier particles fall directly to the bottom of the tank, where they accumulate and augment the thickened strata. The lighter particles of coal spread above the impurities. When sufficient solids have accumulated in the tank the jets passing among them cause pulsations, which allow the coal to rise and form a separate stratum above the impurities, permitting the heavier particles, consisting of sand, slate, bone or other ash-forming material, to form a bed on the bottom of the tank.

Jets Loosen Impurities in Bottom of Tank

As the coarse solids thus accumulate the jets loosen the impurities so that any coal particles imprisoned by them are released and thus can pass upward in the liquid. The bed of impurities usually is allowed to accumulate to a considerable depth, as it will be more completely impure at the bottom, from which point it is discharged either continuously or intermittently.

As the bed of impurities is increased in depth it will contain a higher percentage of coal toward the top, and as the column ascends it will merge into clear coal. Therefore the mergence may be automatically controlled by regulating the discharge of impurities. (See Fig. 2.) This will be especially desirable where the coarse particles discharged are reground so that further impurities may be released.

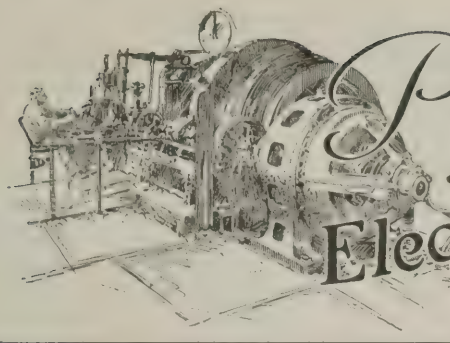
The coal, forming a suspended stratum or column above the impurities, automatically stratifies with its heavier particles below, graduating upward to the finest. The greatest upward velocity of the liquid is between the coarser particles, through which it first passes. As the liquid rises, the tank widens and there is less obstruction from solids, and so the velocity of the liquid decreases. The upward current gradually subsides to minimum velocity and holds only the finest of the coal in suspension. Some of the extreme fines may flow with the circulation through the pump, but, due to the velocity in the tank, they must always return upward into the current when released into the tank by the jets.

When a charge has accumulated, the content of the different strata may be continually discharged from one or more outlets, the hydrostatic pressure being sufficient effectively to force coarse material from the lower outlets, the finer sizes being easily extracted from outlets higher up. To conserve water it is essential to keep the coal strata at maximum density before discharging. Under ordinary conditions, if the coal is fed into the machine with excess dilution, all excess water will escape at the overflow in a clear state.

The apparatus contains no gears or complex mechanism of any kind. It is a rugged, simple, completely balanced machine and is almost foolproof. The circulating medium has a balanced head. There are no torsional stresses or unbalanced resistances, and there is little greater stress on the mechanism when operating at full capacity than when at absolute rest. This is due to the fact that all moving parts are balanced in liquid suspension.

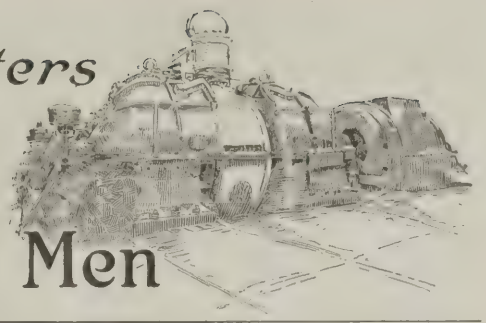
The machines can be modified so as to be purely classifiers for extremely fine coal or they can be used as classifiers for fine grinding machines or they can be employed for separating fine coal into merchantable sizes. As thickeners for gathering and thickening fine coal from water they have great capacity and will produce an extremely dense discharge.

When operating in connection with a fine grinding machine for eliminating impurities and producing fine coal for special purposes, water admitted through the water inlet at the right (see Fig. 1) will assist in regulating the discharge to extreme fineness.



Elements of Mining

FULL credit should be given to George J. Young for his book entitled "Elements of Mining." The material in it is well selected and carefully grouped. It follows a well-conceived plan and evidently represents many years of methodical correlation.



Unfortunately for the coal-mining man, the author does not have the coal problem definitely in view. It seems even to appear as an aside or after-thought, even as any unwelcome, unbidden guest. As a result the book is better suited to the metal-mining man than to those whose duties are connected with the extraction of coal. Yet it must be confessed that this is in fact a merit in the book rather than a defect. Many readers would testify that a book with a predominance of metal-mining was just exactly what they wanted.

The treatise also keeps closely to a certain class of information and does not attempt in its 671 pages, measuring $5\frac{3}{4} \times 9$ in., to cover the multifarious side issues of the mining problem, the mechanical and electrical equipment or the subject of preparation.

The duties of mining, mechanical and electrical engineers at mines tend to overlap and the information needed by each is difficult to define with exactitude. This book, however, is written for the first of the three and especially for the man who is engaged in metal mining. To coal-mine engineers it may be said, however, that no technician safely can afford to shut his eyes to the developments of sister sciences, so readily may the achievements and concepts of one be transferred to the other. The book is published by the McGraw-Hill Book Co., 370 Seventh Ave., New York City.

Practical Pointers for Electrical and Mechanical Men

An Important Point with Reference to the Polarity of the D.-C. Generator

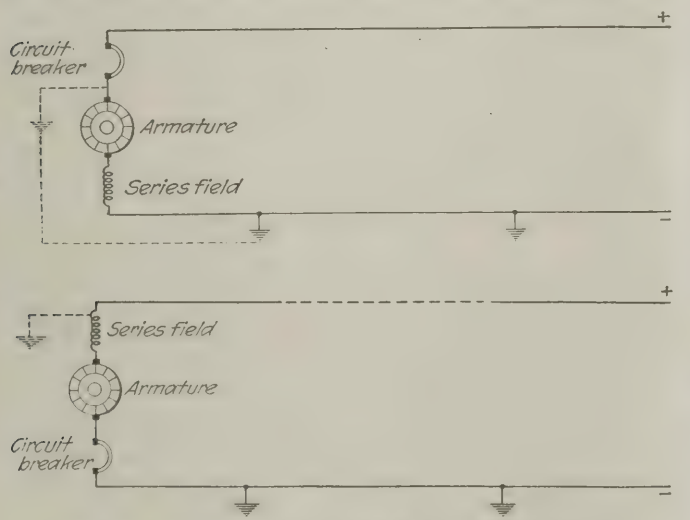
Where there is danger of lightning which connection and polarity should be used?—Can the circuit breaker be located to relieve short-circuits in the generator?

I HAVE heard it mentioned that there are some installations of generating equipment at coal mines where the series field winding is operated as the positive of the generator feeding direct current to the haulage and general direct-current system.

Sometimes one of our generators builds up with the wrong polarity but we are always careful to change it so that the armature lead is positive.

If there are any particular advantages in operating the machines with the series-field lead positive I would like to know.

A READER.



Here is a page or two of what you have been looking for. Not that it is new in "Coal Age" but it is brought together particularly for your convenience. Send in your ideas, experiences and questions. These pages of Practical Pointers are for you.

One of the greatest advantages and arguments in favor of making the series field end of a generator positive is attained where the feeder line or trolley line is run on the surface of the earth some little distance before entering the mine. Here the trolley line or feeder on the surface is exposed to lightning.

Looking at Fig. 1, where the armature lead is positive and the circuit breaker is in the positive line, a stroke of lightning near the lines in the case of the negative line would run off to ground because it is grounded, but in the case of the positive it probably would seek a path to ground through the machine; if lightning struck the armature it probably would break down the insulation there. The armature winding is difficult to repair and, furthermore, the circuit breaker would be of no avail in breaking the short-circuit thus resulting, as shown by the dotted lines.

In Fig. 2 the series field is positive and the circuit breaker is in the negative lead. A stroke of lightning now coming in on the positive line no doubt would break down the insulation of the series field. The series field insulation usually can be more readily repaired than the armature insulation; also, since the circuit breaker is in the grounded side the short-circuit resulting from the breakdown of the series field would be immediately opened by the opening of the circuit breaker.

Frequently machines are designed so that the series field should be the grounded side and of course not heavily insulated. Under these conditions it is not always possible to make the series field positive and ground the other lead, because this puts full voltage strain on the insulation of the series field.

TWO CONNECTIONS FOR THE D.-C. GENERATOR

In the first figure it is evident that a ground between the circuit-breaker and armature is not cut off by the circuit-breaker. The second figure shows a connection which may be used to advantage where the positive line is exposed to lightning disturbances.

An Easy Method for Obtaining the Diametral Pitch of Gears

ONE of the most difficult pieces of repair equipment which the electrical or mechanical man about the mines is called upon to order is a gear or pinion. Numerous catalogs and bulletins are published and available around the mines which explain various formulas about the design of gears and gear teeth. In these bulletins the pitch circle, diametral pitch, tooth root, tooth addendum, etc., are explained in detail. All of these points are interesting, but when a new gear is to be ordered the difficulty lies in this fact: Who remembers the mass of gear formulas he thought he had learned?

The importance of having the proper pitch of the teeth in a gear or pinion needs no argument, yet the question of determining this pitch from an old gear perhaps several miles underground is a real difficulty for almost anyone.

There are two ways of measuring the tooth pitch of gears, one is called circular pitch, which generally is used to measure the pitch of cast gears, and the other

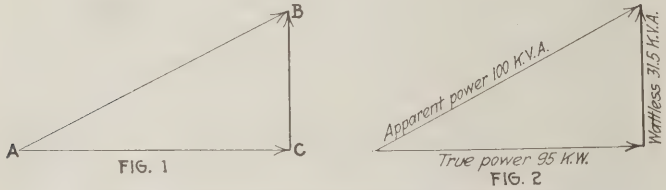
is known as the diametral pitch, which generally is used to designate the pitch of cut gears. It is this last group which is most popular and the one which we will now consider.

First of all it is important to understand what diametral pitch means. Diametral pitch is the number of teeth per inch of pitch diameter, or, in other words, the result obtained by dividing the number of teeth in the gear by the diameter of the pitch circle, expressed in inches. For example, a gear may have 69 teeth and the diameter of the pitch circle be 23 in.; in this case 69 teeth ÷ 23 in. gives 3 diametral pitch. Note that this 3 is not 3 in. It is important to remember this point because 3 in. would be altogether incorrect, and would result in a gear far different from that desired.

The diametral pitch of a gear usually is an even number or common fraction thereof, the most popular for mining equipment being 3, 3¼, 3½ or 4.

So far we still have that difficulty in determining what the pitch diameter of our gear is. Fortunately, certain relations exist in cut gears which greatly simplify our difficulty. Perhaps the easiest method of obtaining the diametral pitch is from the formula: number of teeth + two ÷ by outside diameter = the diametral pitch.

In other words when getting data for a new gear the electrical or mechanical man need only have a rule for measuring the outside diameter of the gear and count the number of teeth. This information will give him or the manufacturer sufficient data for determining the diametral pitch.



Example: A gear has 69 teeth and the measured outside diameter is 23⅝ in. Therefore, 69 + 2 ÷ 23.625 = 3.005. The actual outside diameter of the gear was 23.667 in., but 23⅝ or 23.625 in. was the measured diameter with the rule, which shows the diametral pitch to be 3, since the calculation with the slightly inaccurately measured outside diameter indicates close to 3 and far distant from either 2¾ or 3¼.

An Advantage of the Reactive-Factor Meter Over the Power-Factor Meter

WHEN buying switchboards and equipment for alternating-current systems we frequently have the choice between power-factor meters and reactive-factor meter. All of our meters at present are power-factor meters, yet I would be pleased to have a discussion of these two meters in your paper.

PURCHASER.

A discussion on these meters would no doubt be interesting. The subject of power-factor is one which most customers were introduced to by the power companies during the war. Many coal operators had not given much thought to the matter of power-factor and are now paying the costs. The question of high wattless current in the lines and equipment is not only a live one for the purchaser of power, but also for the isolated power plant at the mine.

FIGS. 1 AND 2 SHOW VECTOR RELATIONS

In Fig. 1 the ratio $\frac{AC}{AB}$ represents power-factor and $\frac{BC}{AB}$ reactive-factor. Fig. 2 shows a condition of high power-factor but a large proportion of wattless kva.

The principal difference between the power-factor meter and the reactive-factor meter is that one indicates a ratio between true power and apparent power, sometimes called the cosine; while the other indicates a ratio between the wattless component of apparent power and the apparent power, called the sine.

With reference to Fig. 1, power-factor is the ratio AC ÷ AB, while reactive-factor is the ratio BC ÷ AB. In the figure AC represents true power, BC wattless component and AB apparent power.

Under some conditions the reactive-factor meter seems to be the more desirable; to illustrate, Fig. 2 shows a right triangle representing 95 kw. true power, 31.5 kva. wattless component and 100 kva. apparent power.

The power-factor meter under these conditions shows 95 per cent, while the reactive-factor meter shows 31.5 per cent. In this case the power-factor meter reading of 95 per cent is good, but althought it is what is called good, it does not give any indication of the amount or ratio of the wattless component, which it will be observed is one-third of the true power, thus indicating that the wattless component is of a very appreciable amount.

Why Choose 440 Volts for Distribution Instead of 220 Volts?

WE HAVE a new bank of transformers for use on a new line which can be laid out for 220- or 440-volt equipment. The bank of transformers has a secondary winding suitable for either 220- or 440-volt connection. What are your recommendations as to which voltage we should use? REPAIRMAN.

From the question as presented it is probable that the equipment to be used on this line will consist for the most part of induction motors.

Induction motors are made to operate satisfactorily on 10 per cent under-voltage or 10 per cent over-voltage. This being the case the low limit of voltage on the 220-volt motor is 198 volts or an allowable 22-volt drop; the low limit of voltage on the 440-volt motor is 396 volts or an allowable 44-volt drop. The 440-volt motor therefore gives us twice the permissible voltage drop allowed the 220-volt motor.

For a given load the current at 440 volts will be half that at 220 volts; therefore the size wire, from this point of view alone, would be half that for the 220-volt load.

The two factors of greater permissible drop in volts and reduced current in favor of the 440-volt system mean that the size wire for the 440-volt distribution need be only one-fourth that required with 220 volt.

Get out your pencil and paper and figure this out for your personal satisfaction; it is an interesting point.

As a result of such advantages and economies the development in the application of alternating-current is along the lines of higher voltages. A few years ago it was considered a dangerous and novel feat to use 2,300 volts in the mines but today it is common to operate even small motors at 2,300 volts or higher, thus obtaining better operation from the equipment.

Reforesting Denuded Timber Land a Means of Reducing Freight and Material Costs of Roof Support*

Timber Shortage in Sight—Trees Should Be Cut When Mature, Leaving Smaller Trees Uninjured for Later Cuttings—Individual Better Than State Ownership—Ill Effect of High Local Freights and Excessive Taxation

By E. S. Stackhouse†
Shickshinny, Pa.

THE growing scarcity of timber of all kinds and the increasing exhaustion of producing areas brings to our attention problems regarding the cultivation, production and marketing of timber, not alone for general use but more especially for mine purposes. Particularly acute is the need of the anthracite districts of Pennsylvania. The policies of the past have brought about present conditions, and it goes without saying that these are far from satisfactory. As we look back on the last thirty to forty years we can see in relation to our timber supply nothing but blunders and neglect, ignorance and wastefulness.

A resource and an industry of prime importance has been allowed, through get-rich-quick methods, to dwindle into insignificant proportions just as the need for its ministrations is greatest. Would that man's foresight might be at least in small measure equal to his hindsight. The trouble is that during this period there has been no broad policy at all and nothing constructive until within the last few years and the efforts made since the importance of the issue has been recognized have all been too puny to stay the big economic fact that a timber shortage is in sight.

A Spoliation and Restoration Forest Policy

The government has adopted a policy of conservation which, however, applies largely to the Western domain. Pennsylvania and other near-by states as well as the larger coal companies have adopted a reforestation policy and are carrying it out vigorously. This takes the land after it has been denuded of its timber, and by a long, tedious and costly process restores in part its timber productivity, but the pity of it is that forest lands should ever have been allowed to become a wilderness when a far-sighted constructive policy in their handling would have kept them forever in a productive state. This is a crime against civilization and posterity, and, as usual, our children will pay the bill. It is worth our while even in this late day to examine the matter critically and to see what may be done to ameliorate the situation—to study how we may change our present destructive policy to a constructive one. The two main elements which enter into this problem are wrong methods of cutting and neglect.

The section in question, the northeastern portion of the United States, has been blessed with some of the finest forest-growing conditions in the world, with a great variety of timber growth well adapted to the varied needs of its inhabitants. The conifers which so abundantly clothe its valleys are easily reproduced in a natural way by seedlings as quickly as an opening is made in the ground, and the hard woods which cap its hills and ridges immediately respond through sprouting to the great laws of reproduction. Nature has done well, but man has deliberately defeated her most beneficent plans. He has walked with the precision of a devastating army throughout the length and breadth of the land and for the sake of a little quick gain, which has been followed by neglect, has absolutely destroyed a golden heritage, a most precious possession—the reproductivity of our forests. The devastation of the Germans was child's play to the destruction wrought by the "lumberjacks" in our own land during the past fifty years.

But as we talk time passes. It serves no good purpose to dwell on the mistakes of the past except as we learn the lessons they teach. Our problem now is to

TREES ON AREA REFORESTED AND GUARDED FROM FIRE

Scene on the property of the Kingston Coal Co. The average smoker or hunter might hesitate to devastate a thrifty growth of timber like this but he counts the early stages of timber development as of little importance and throws his matches and builds his fires without scruple.

*Article prepared for *Coal Age* but read before Foresters' and Timber Owners' Meeting at Wilkes-Barre, Pa., an assembly at which most of those present were interested in the development of the burned-over and reforested lands of the anthracite companies.

†President, E. S. Stackhouse Coal Co.

look into the needs of the future and prepare as best we may by wise, constructive and courageous action to meet them. In order to accomplish this we must analyze somewhat our present methods of cutting and make such changes as the conditions demand. It would seem that in the serious situation now facing us every branch of the trade—owner, producer, dealer and consumer—would cheerfully co-operate in any common-sense methods that would conserve their interests for the future and perpetuate their chosen industry.

We have inherited an entirely wrong conception of handling our timber lands, coming down from the days

ARTIFICIALLY PLANTED AREA AFTER A DECADE OF PROTECTION AGAINST FIRE

European larch of 10 years' growth may be seen in the rear. In the foreground is Norway spruce of 9 years' development. These trees are on the property of the Kingston Coal Co.

of our unlimited primeval forests. Methods that might have been excusable in those days may be absolutely inexcusable in the changed relations of the present. Germany, France, Switzerland and other European countries have long since been forced to adopt improved methods, and our time is at hand. Will we have the courage and determination to enforce those measures which are absolutely necessary to conserve our already sadly depleted forest reserves?

Planting forests is all right but the old adage applies—an ounce of forest conserved is better than a pound of forest planted. Coming back to basic facts, the trouble is that by wrong methods we are destroying our forests by wholesale. We cut them clean and then abandon them. We kill them ruthlessly and then do not even obtain the services of an undertaker to care for the remains. Then along comes the kindly disposed, fatherly State, takes over the corpse and by ample funds, tender nursing, loving care and watchful waiting, attempts to bring the dead to life again. I submit that this is not fair, that it ought to stop and stop quickly. The love for quick gain ought to submit to a broad conservation policy for the good of all.

Such methods of cutting as will preserve our forests should be put into practice. Provision should be made for the reproduction of timber and every protection against fire afforded. When this is accomplished we can look forward to a time when the forest growth will take care of the people's needs, which will, of course, adjust themselves to the supply. Then our forest problem will be placed on a sound economic basis instead of the uncertain, slipshod, headlong conditions now prevailing. The methods needed are exceedingly simple. To apply them is not so easy.

First of all, education is necessary, to create a wholesome public sentiment that will welcome and stand by any measures necessary to the end in view. It is surprising how a new policy will change the whole attitude of a people. Evidence of this may be found in the public viewpoint as to forest fires. The "Smith and his woods be damned" attitude has changed to "I'll be glad to help you put it out." Every timber owner and lumberman realizes the devastating effects, the losses, the ruin of present policies and, I believe, would submit more easily than we think to a curtailment of his privileges and a slight regulation of his methods to the advantage of all. He would soon learn that his interests in improved methods would be largest of all for it would protect him by assuring him that his industry would last indefinitely. The public is ready right now, in my judgment, for such action as would assure protection to our remaining forests.

Every Clearing Should Be Proved Necessary

Broad visioned and firm, yet fair and practical legislation should be passed and strictly enforced preventing any owner from cutting any forest clean except for a clearing that can be justified. No cuttings should be allowed under certain limitations except for improvement purposes. The protection of young timber should be encouraged in every possible way. By this method the conditions of the problem would be radically changed. All privately owned forests would immediately become part of a general conservation system. Every forest owner would stand for protection on account of the equity which he is forced to retain in his forest. The general indifference to cut over land would give place to an increasing interest and to a careful study on the part of owners to get by prudent management the greatest productivity from their holdings; self-interest thereby advancing conservation.

The greatest force for conservation remains with individual owners. They should be encouraged, instructed, urged and legislated into handling their forests in the interest of conservation. In the final analysis it is their job, and I submit that a host of interested owners scattered all over the state, living mostly near their holdings, incited by self-interest and economy can better work out this problem than the State. It is a question that belongs to the State only should others fail. The Commonwealth cannot do it as well nor as cheaply and should not undertake it except as a last resort. What has been done by Pennsylvania and other states has been forced on them by the mistakes of private ownership.

It is not my intention to discuss the importance of care in culling, cutting and handling to protect the younger growth and the importance of greatest and best utilization. These are details of the general prob-

lem of conservation and bear an important part in the policy as a whole.

Other matters now may be suggested whose influences are not so obvious, but are nevertheless real in their bearing on the question. One is the fact that the local railroads serving the territory in question, the anthracite coal roads, are discriminating heavily against local timber shippers in their rates and favoring shippers of the South and West. They probably have their own arguments for this policy, but I venture to say that in arriving at their conclusions they have not taken into consideration the influence which a fairer rate, meaning a greater realization to the local timber owner, would have had on his attitude toward conserving and preserving his timber supply.

I wish to suggest that a close community of interest should and must obtain between the consumer and the grower of wood products if the best results are to be attained. The purchaser should understand the problems of the lumberman in his relation to the general conservation scheme and be willing to adjust himself in as far as he can to the interests of the scheme as a whole. He may have to discard some of his old customs, theories and requirements, but he will be glad to do this when he sees the interrelation of his business with the conservation idea.

Purchasing Agents Should Aid Timber Men

One of the most important groups in local timber conservation should be the anthracite coal companies' timber purchasing agents. They are being forced by economic conditions to open their eyes to the problems involved, but if they were fully awake there would be less discrimination and greater co-operation in their contact with timber growers. To cite one instance, if during the devastation caused by the chestnut blight the purchasing agents had found ways and means to use more of the dying chestnut in lumber and mine timber, thousands of cars of valuable forest products which have been going to waste could have been substituted for other material which might then have stood untouched for the future, when it will be so badly needed.

The tax question is most intimately associated with forest conservation where this work is being undertaken by individuals. The State has a great advantage over the private owner, but inasmuch as it is greatly concerned that individual owners shall practice conservation and reforestation, every effort should be made to lighten the burden on forest lands undergoing rehabilitation or subject to conservation. A long series of years must elapse while nature by a slow process restores the wealth which has been taken from the land. Forest lands on which conservation methods are practiced are put at a great disadvantage because the costs of cutting, skidding and hauling are higher than with the old clean-sweep methods of lumbering. As a matter of fact the interest on the investment, the taxes and the interest thereon for many years, the cost of fire protection, the hazard of investment and the long deferred return must cause any individual to pause before attempting to rehabilitate in forest growth a denuded piece of land. Finally to cap the climax the federal government, according to present laws, comes along and says that when the long-deferred harvest is reaped from lands purchased since March 1, 1913 (that deadly dead-line date), the original investment alone, which is only a small fraction of the total investment constantly increasing by accruing interest, can be depleted and that all other net returns are subject to federal income taxes. In the face of conditions such as these it takes a courageous investor and one of large faith to attempt forest rehabilitation on any considerable scale. The whole problem is so acutely serious that all who are familiar with it should unite to obtain a fair show to the man who seeks to perform a great public service and at the same time obtain a practical and sound investment for his posterity. Our own and other states have done much to lighten the tax load on land under timber, but the problem is one that goes to the heart of conservation and deserves careful thought and action especially in its relation to federal taxes.

The railroads and mining companies are showing greater interest in forest protection. Nevertheless one of the principal causes of fires is the cloud of ashes from their locomotive stacks. These in both large and small locomotives should be equipped and carry at all dangerous times some form of spark arrester that will arrest. Many mining companies as well as the railroads every year through sheer carelessness unnecessarily burn over thousands of acres.

ALL THAT REMAINS AFTER A FOREST FIRE

The ground, no longer protected by trees or leaves is easily swept away by drenching rains, filling up the water courses and giving any future vegetation reduced humus for sustenance. Many years will be required to overcome this handicap.

A pointer should be given to forest owners whose chestnut has been destroyed by the blight. The roots on this land are now sprouting and forests of the same kind of tree probably will ultimately be re-established. We believe that many of these sprouts will be immunized from the blight, just as mankind is freed from certain diseases by once having been subjected to them. We are becoming more confident of this each year and now have on our own lands four-year sprouts free from blight. We notice these have a lighter colored bark than those they succeeded. Let us encourage these growths in every way possible, especially in the way of fire protection, for if this land is burned over it probably will forever lose all chance of ever coming back in chestnut, which in many ways was our most valuable timber.

To sum up, let us by every force of education, encouragement and law protect our remaining forests from denudation. Let us make it easy and profitable to conserve timber and thus encourage forest rehabilitation and conservation by individuals and corporations, and wherever the people fail individually to promote these ends, let the State carry forward its splendid plans to reforest those large areas which were so blindly denuded many years ago.

Problems of Operating Men

Edited by James T. Beard

Coal Brokers vs. Co-operative Sales Agencies

Possible Valuable Service of Coal Brokers Not Fulfilled in the Past—Little or No Invested Capital—Co-operative Sales Agencies Needed

IN SUPPORT of the brokerage system of marketing coal, which has grown to large proportions during the past few years, M. R. Atkinson writes in an interesting manner, *Coal Age*, Mar. 22, p. 493; but his arguments are not convincing to my mind.

It will be readily agreed that the coal broker does, under present marketing conditions, fill an economic need. He renders, to both the industry and the consumer alike, a distinct service by giving the buyer a wide variety for selection and the operator a broader market for his products. It cannot be denied, however, that he has not been scrupulously conscientious in the performance of this service or that it has not been economical in respect to the public or beneficial to the industry.

Logical Result of Brokerage Systems

It is probable that an unbiased survey of coal-market conditions covering the past few years would show that the brokerage system is largely responsible for the public antagonism to the mine owner. During periods of coal shortage the broker has skimmed the cream from the profits of the mine owners and fleeced and outraged the public.

Analysis, I believe, will show that this is the logical and unavoidable outcome of the system. The broker has no heavy investment in mines and equipment, and takes no special interest in the establishment and maintenance of those valuable commercial relations between producer and consumer that insure fair prices and an honest product. His actions are governed largely by the desire for immediate profit.

If this is the true condition in respect to the brokerage business the best interests of the producer and the consumer alike can be served by the complete elimination of the coal broker and the setting up of other machinery or employing methods that will perform a more useful service than the broker has yet rendered the industry. The functioning of a properly organized system would certainly be free from the evils inherent in the brokerage system.

Co-operative Sales Agencies the Remedy

The solution that most readily suggests itself to my mind is the organization of a system of co-operative sales agencies, in the different fields, sufficient to take care of the output of those mines whose production is too small in volume to justify the maintainance of a private sales office.

This would probably embrace not more than twenty per cent of the total production of the district; but the efficient distribution of even this proportion, at a fair price, would do much to clear the entire industry of the charge so frequently made of profiteering and unfair dealing.

The co-operative sales agencies would be financed by the mine owners and the actual selling expense would be added to the mine price. This would insure lower prices to the consumer and in many instances, better profits to the operator.

————, Ky. KENTUCKY OPERATOR.

Superstition Giving Place to Facts

Beliefs of early miners in the supernatural—Advance in knowledge dispels superstitious fears—Risks common to mining to be avoided.

SOME time ago, I remember reading an interesting article that dwelt on the superstitious beliefs of miners, having particular regard to accidents in mines (*Coal Age*, Vol. 22, p. 326). Since reading the article, I have done considerable thinking along this line and recall many things that have occurred in my own experience in that connection.

It is only fair to say that when first going into the mine, years ago, I possessed many of the same superstitious fears and beliefs. Among a large class of miners many of these beliefs still prevail and influence, to a large extent, both their lives and actions.

Many a time have I heard a miner say, "I don't feel like going into the mine today. I have a fear that something is going to happen." Still, the man would go in and nothing unusual took place.

No Wonder That Not Knowing the Causes Mine Occurrences Excited Fear

In the early days of mining, mysterious noises were heard in the coal; strange occurrences were observed in sections of the mine; lurid flames would burst forth in volume, leaving sulphurous fumes that could not be breathed; lights would go out and could not be relighted; and miners would become unconscious and die from no apparent cause. Is it strange that the poor miner, ignorant of the conditions that surrounded him in the mine, ascribed these doings to spirits or the work of a gnome?

There is a one common belief among miners that I first learned when a boy. A number of old Welsh miners told me that when the rats begin to leave a section of the mine, it is time for the men to go. They said there is sure to be a heavy cave in that section when the rats are seen to scamper for other quarters.

Perhaps there is more reason for this belief than for some others I could mention, inasmuch as these rodents run up and down the timbers and invest every nook and crevice of the workings. They are alert to

every noise and movement about them and it is not so strange that they should leave the place in a body when danger was imminent.

Not so reasonable, however, was the claim of some miners, who found their oil cans running low, that these knowing creatures would run their tails down the spouts of the cans and then lick the oil from their tails. The idea was a curious invention of the mind and not given general credence.

Advance in Mining Knowledge Explains Mysteries of the Mine

The rapid advance in the knowledge of mine gases and geological conditions, a little later, served to explain many of these mysterious (?) happenings. The discovery of the presence of mine gases explained both the lurid flames and the suffocating effects that produced unconsciousness and death when there was no apparent cause; while the mysterious noises heard were shown to be the working of the strata following the extraction of the coal.

It is hard to understand how intelligent miners will still hold to the belief mentioned by Mr. Edwards in the article to which I have referred, that "if a fatal accident occurs in a mine two more are sure to follow." The better judgment of men should teach them that the occurrence of a fatal accident has nothing to justify the claim that others will follow. Neither does an accident on the first trip down into the mine, in the morning, forecast bad luck for the day.

Let an accident occur in a mine and you will frequently hear a miner remark, "I just felt it in my bones that something was going to happen today." It is an easy matter for us to say, after a thing has happened, "I told you so." But, if such a presentiment was true, it should have had the effect of a forewarning that would have avoided the occurrence.

Let us come to believe and understand that behind every occurrence there is a reasonable cause and put aside the superstitious beliefs that have no basis in fact. For example, let us realize that the lack of ventilation in a gassy mine forecasts a gas explosion. Or, taking no precautions in the operation of a dry and dusty mine, especially where the coal is blasted with black powder, means, sooner or later, a dust explosion.

Failure of Officials and Men to Perform Duties Brings Disaster

Failure to properly timber a treacherous roof, or to make suitable provisions for safety on haulage roads and travelingways, or a failure to enforce safety rules and regulations, each and all spell disaster in the near future.

Not long ago I was looking over a mine with the foreman when we came to a bad fall, in an old abandoned working. Though the roof was hanging in a dangerous manner, the foreman insisted on going over the fall and went over alone, as I refused to take the risk, there being nothing to be gained by so doing.

With reference to the statement: "When a man takes a job in a mine he assumes his own risks," it is true there are many risks in the mining of coal. However, it does not occur to me that miners are any more indifferent to the dangers pertaining to their calling than are workmen of other occupations.

Compare, for example, the iron worker driving bolts at the top of a fifteen- or twenty-story building in the course of construction. While he is indifferent to the danger of his position, the same man would not consent to work in a mine, because of its assumed danger. On the other hand, the miner could not be induced to expose himself to the danger of working astraddle of an iron girder several hundred feet above the ground.

Each of these workers regard the other's occupation as a more dangerous calling than his own. The truth of the matter is that continued exposure to these dangers has a tendency to make the worker disregard them. While it is well for every worker to have a wholesome regard for the danger to which he is exposed, a superstitious fear or dread of impending danger has no tendency to safeguard the miner or make him immune from accident. My observation is that men who are naturally nervous and fearful of accident are, perhaps, more subject to such occurrences than those who are less concerned, regarding their own safety.

John Rose.

Dayton, Tenn.

Avoiding Squeeze in Miller Seam

Soft nature of coal invites squeeze—Action once started difficult to control—Good barrier pillars needed to safeguard entries.

ONE of the essential things to be borne in mind when laying out or planning the inside workings of a mine is the liability to a creep or squeeze in the later development of the mine. This thought has been impressed on my mind, particularly by reading the several letters regarding the working of the Miller seam, in Pennsylvania.

Those familiar with the conditions existing in that seam know that the coal is of a soft nature and crumbles readily. To make matters worse, the seam is underlaid with fireclay and when this becomes soaked with water, in the working of the mine, it is not able to withstand the heavy roof pressure coming on the pillars.

We all know that a creep or squeeze once started cannot be stopped in that particular place. All that can be done is to keep it from spreading to other sections of the mine. This may often be accomplished by the rapid extraction of pillars over a considerable area, so as to give sufficient room for a good clean break to take place in the roof.

Much will depend on the strength of the overlying strata. If the roof is tough and strong it will be necessary to extract a number of pillars, in a group, before a good clean break will occur. Following such a break, there will seldom be any further trouble from squeeze, provided the pillars are taken out clean and no stumps or timbers left standing in the waste.

Protection by Good Barrier Pillars

I have referred to the need of a good plan in laying out a mine and want to say, here, that the barrier pillars protecting the main headings should not be less than 150 ft. in width and the entry pillars at least 40 ft. wide if squeeze is to be prevented in working the Miller seam. On panel entries the barrier pillars should be 100 ft. in width.

While these dimensions may seem unnecessarily large, they will serve to arrest a squeeze should one occur, and prevent its crossing the headings. Where this system is adopted, I would favor driving the rooms and extracting the pillars as the butt headings are advanced. But room pillars should never be extracted closer than 40 ft. from the butt headings.

On the other hand, if there are no large barrier pillars left for the protection of the main and panel headings, I would drive the butt headings to the limit of the panel, before turning any rooms. The rooms should then be started from the inby end of the heading and when a sufficient number of these have reached the limit, the pillars should be drawn back in a group of six or more, so as to provide a good area for breaking the roof. I feel sure that such methods as these, if followed, will prevent any disastrous squeeze or creep.

Kantner, Pa. GRIFF GRIFFITH.

Standard Rule for Estimating Available Tonnage of Coal per Acre

Improved methods of mining have given increased extraction of coal—Old rules for estimating available tonnage per acre no longer apply.

REGARDING the question of formulating a standard rule for estimating the tonnage of coal available, per foot-acre, in a given property, as suggested by J. F. Healy, *Coal Age*, Feb. 15, p. 302, it seems to me that his assumed arbitrary figure of 1,800 tons per foot-acre will not fit all cases.

It is true, as Mr. Healy has stated, that this figure should be multiplied by an assumed percentage of extraction, which will allow for the different results obtained in the mining of coal. But there is another factor that must be taken into consideration before we can establish a general rule that will cover all conditions. We must allow for the varying hardness or specific gravity of the coal.

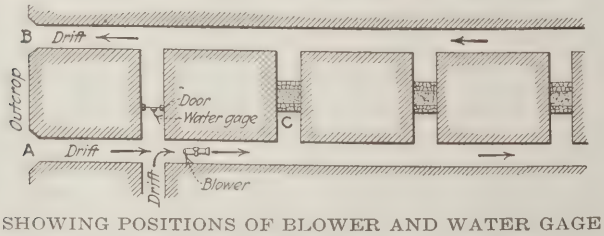
Reports of the U. S. Geological Survey and the Bureau of Mines show that the specific gravity of bituminous coal varies from 1.21 to 1.44, in different localities. Estimating on a short ton of 2,000 lb. and taking a coal of specific gravity 1.21 weighing 1.21 × 62.5 = 75.6 lb. per cu.ft., the number of cubic feet per ton of this coal would be 2,000 ÷ 75.6 = say 26.5 cu.ft.

Again, making the same calculation for a specific gravity of 1.44 shows that such coal would weigh 1.44 × 62.5 = 90 lb. per cu.ft., which gives 2,000 ÷ 90 = say 22.2 cu.ft. per ton. The tonnage per foot-acre, in the first case, is 43,560 ÷ 26.5 = say 1,644 tons. The estimated tonnage in the second case is 43,560 ÷ 22.2 = say 1,960 tons.

Clearly, the average figure of 1,800 tons, per foot-acre, lies between these two estimates and is only for use in making a rough estimation of the available tonnage when the specific gravity of the coal is an unknown or an undetermined quantity.

The point to which I wish to draw attention is that, in order to make an accurate estimation of the available tonnage, per foot-acre, it is not only necessary to know the percentage of extraction of the coal; but the estimate must be based on a fairly close value representing the average specific gravity of coal in the seam.

University, Ala. H. D. PALLISTER.



Inquiries Of General Interest

Effect on Water Gage Outby of Blower

Small Blower Located Inside Drift Mouth — Position of Water Gage Outby of Blower — Effect on Gage in this Position

IN A SMALL drift mine where I am employed, the ventilation is secured by means of a small blower located just inby from the mouth of the drift. The arrangement is shown in the figure, which though roughly drawn will help to make my meaning clear.

Not long ago, I attempted to get a water-gage reading, for the purpose of estimating the power on the air

SHOWING POSITIONS OF BLOWER AND WATER GAGE

and showing what efficiency we were getting from the blower installed in the drift. As indicated in the figure, the water gage was placed on the main door, in the first crosscut between the intake and return entries and, in this position, was outby from the blower.

Much to my surprise, the gage gave no reading and it looked to me as though a logical conclusion would be that we were getting no efficiency from the blower, though that hardly seemed to be the case, inasmuch as a fair current of air was passing in the mine.

Kindly explain why it is that the water gage gave no reading where it was placed. Also, explain where the gage reading should be taken for the purpose of determining the power on the air. W. B. L.

Besoco, W. Va.

The reason that the water gage gave no reading, in the position indicated in the figure, is that the pressure on both sides of the door where the gage was placed is practically the same; namely, the atmospheric pressure. Referring to the figure, the air entering the mine at *A* is under the atmospheric pressure, until it has passed the blower where the pressure is increased by an amount due to the action of the blower. This increase of pressure is the measure of the mine resistance, which is its cause.

Starting from the blower and following the air current in its course throughout the mine, the pressure moving the air decreases regularly as the resistance becomes less and less, until it is finally *nil* at the mouth of the discharge opening marked *B* in the figure. It is, therefore, clear that the pressure on the air both at *A* and *B* is only that of the atmosphere and, there being no difference of pressure, there can be no water-gage reading at that point.

In order to obtain a water-gage reading representing the resistance of the mine, the gage must be moved to a point inby of the blower, say at the second crosscut, marked *C* in the figure. Or, a partition could be erected at the blower and arranged so that all of the air passing sufficient size to make this arrangement practicable. into the mine must pass through the blower, if it is of In that case, the water-gage reading would be taken on the partition erected at the blower.

Examination Questions Answered

Examinations Under the Mine Act, Alberta, June, 1922

(Selected Questions)

QUESTION—*How should a safety lamp be treated when found to be full of flame as the result of being in an explosive mixture?*

ANSWER—Should this occur in the examination of a mine for gas, it will require much presence of mind, on the part of the fireboss or person holding the lamp, to avoid the danger that is imminent. Any quick movement, particularly in a sidewise direction, would be apt to force the flame through the mesh of the gauze and ignite the gas surrounding the lamp. The lamp should be lowered promptly but cautiously, holding it in an upright position and making no quick movement, which would increase the danger. In no case should the lamp be permitted to remain in the mixture, as the gauze would quickly become heated and the flame pass through the mesh, thus causing the lamp to fail.

QUESTION—*When the fireboss reports in his record book certain dangers he has discovered during his examination, what would then be your duty as mine foreman? If the report applies to the old workings, state how you would proceed.*

ANSWER—The law makes it the duty of the mine foreman to take immediate steps for the removal of the danger, if that is possible. In case it is not practicable to remove the danger at once, it is the duty of the foreman to withdraw all men working in proximity thereto or who may be in any way endangered by reason of this condition. The foreman must see that the place is safeguarded so that no one will run into the danger, not knowing of its presence.

Assuming that the danger reported by the fireboss exists in the old workings of the mine, the fireboss must act according to his knowledge of the situation and take prompt measures to insure the safety of the live workings. In any case, he must make sure that no air passing through the old workings finds its way into places where men are working. The investigation may show the need of sealing off the old workings, or changing the ventilation in such a manner that the air circulating through them will be conducted at once into the main return and pass out of the mine. There must be no delay in safeguarding the situation to avoid possible accident from poisonous or explosive gases finding their way into the live workings of the mine.

QUESTION — *What quantity of marsh gas in air crowded with coal dust will make the mixture explosive? Can this quantity be detected on the flame of a safety lamp?*

ANSWER—An atmosphere crowded with coal dust may be a dangerous condition though no gas is present. The danger will depend on the fineness and inflammability of the coal forming the dust cloud. The fine dust of a highly inflammable coal when held in suspension in the air will readily be ignited by the flame of a blown-out shot or the flame of an ordinary shot when black powder is used, no gas being present. Again, a dust cloud of a less inflammable coal would be rendered dangerous by reason of the presence of a small amount of gas, when neither the dust cloud or the percentage of gas present would be dangerous of itself when present alone in the mine air. Such a small percentage of gas would not ordinarily be detected on the flame of a safety lamp.

QUESTION—*Will coal dust extend a mine explosion throughout the entire mine in the absence of explosive gas?*

ANSWER—Yes. A local explosion of coal dust occurring at the face of a working place will often be propagated throughout the entire mine if the conditions are favorable. That is to say, if the timbers, walls and floors of the roadways, air-courses and travelingways throughout the mine are covered with fine dust and no means have been taken for its removal, with a view to making the mine safe. The extent of the propagation will depend very largely on the fineness and inflammability of the dust, assuming no gas is present. Any isolated accumulations of gas will greatly assist in the propagation of the flame.

QUESTION—*Give your opinion of the best method of rendering coal dust harmless.*

ANSWER—Experiments of the Bureau of Mines have shown that a harmless condition of fine coal dust is only attained when the dust is so wet as to become so plastic that it can be molded in the hand, which is hardly an obtainable condition in mine practice. An adequate distribution of fine stone dust or salt has been found efficacious in reducing explosive conditions in dry and dusty workings. This is not to say that a good spraying system is without benefit in such mines.

QUESTION—*Give your opinion as to the best method of humidifying the air in mines.*

ANSWER—The most successful means to this end is the introduction of steam in the intake current, after the latter has been heated to increase its capacity for absorbing and holding moisture. The air entering the mine is made to pass over steam coils arranged in the mouth of the air course. The steam is allowed to escape from the end of the pipe where it strikes a baffle or curtain to effect a better distribution in the air and a more complete saturation of the air current.

QUESTION—*What percentage of relative humidity would you consider necessary to render a dusty and gaseous mine safe?*

ANSWER—A high percentage of humidity is always desirable in working a dusty mine generating gas; but humidity alone will not make such a mine safe. The best working conditions are attained when the mine air contains from 60 to 70 per cent of moisture. In addition to this care must be taken to prevent any accumulations of gas or dust and to enforce strict regulations in regard to blasting, besides maintaining an ample ventilating current.

Corrections—In the reply to the third question (Mar. 1, p. 381), the second part of the answer should read as follows:

(*b*) The velocity of the air current being 350-ft. per min., the volume of air in circulation is 350 (8 × 12) = 33,600 cu.ft. per min.

Again (Mar. 8, p. 419) in the reply to the third question from the last on that page, the third line should read: 675 ÷ (1 — 0.04) = say 703 ft. per min. This would make the last line of the answer read: 703 × 66 = say 46.400 cu.ft. per min.

March Anthracite Output Equals Record

Anthracite production in March, according to the Geological Survey's revised estimate, based on final data of shipments in that month, was 9,382,000 net tons, including mine fuel, local sales and dredge and washery output. This figure equals the previous high record of monthly production made in March, 1918. An output of 9,000,000 tons per month has heretofore been attained only in the months of March, June, August and October, 1917, and in March, July and August, 1918, which were years of maximum anthracite production and also times of very large washery output.

The total production of anthracite in the coal year 1922-1923 was 56,576,000 net tons, 36.4 per cent less than in the coal year 1921-1922 and 38.3 per cent less than the average for the past nine coal years.

PRODUCTION OF ANTHRACITE IN MARCH AND TOTAL OUTPUT FOR THE COAL YEAR
(In Net Tons)

Coal year	March Production	Cumulative Output Coal Year to March 31
1913-1914	6,863,000	88,323,000
1914-1915	6,654,000	90,298,000
1915-1916	7,964,000	93,318,000
1916-1917	9,026,000	87,949,000
1917-1918*a*	9,382,000	100,372,000
1918-1919*a*	5,190,000	92,790,000
1919-1920	7,935,000	91,790,000
1920-1921	7,677,000	91,130,000
1921-1922	8,757,000	88,909,000
1922-1923	9,382,000	56,576,000

(*a*) Years of very large washery production.

New Production Records Made in March

Record productive activity in both raw and finished products occurred in March, according to the Survey of Current Business reprinted from *Commerce Reports*, while an increasing consumptive demand apparently digested the goods produced without an appreciable increase in stocks. Cotton consumption and pig-iron production broke all previous records since data for these movements have been available, exceeding even the high records made during the war. Steel-ingot production and locomotive shipments were the highest since 1920, and unfilled orders for locomotives made a new high record. Zinc production was the highest since 1917. March production of bituminous coal was exceeded only twice since 1920—in January, 1923, and March, 1922. The production of anthracite was the greatest since August, 1918.

Retail sales both by 10c. stores and by mail-order houses surpassed all previous records for this month since 1920, at the peak of high prices. Car loadings were the highest on record for this time of year. The wholesale price index advanced two points, being the highest since February, 1921.

Consumption of cotton by textile mills in March broke all records, and at 623,105 bales was about 8,000 greater than in May, 1917, the previous high month. More spindles were active in March than in February. Export of raw cotton declined to 318,210 bales in March. Imports of cotton, exclusive of linters, declined to 53,219 bales. Prices of cotton and cotton goods made substantial advances during March. Silk deliveries to mills declined from the high point reached in February.

Pig-iron production broke all previous records in March at 3,521,275 tons, and steel-ingot production, allowing for companies not reporting, amounted to 3,888,897 tons, the highest since March, 1920. Unfilled orders of the United States Steel Corporation increased to 7,403,000 tons, the highest since January, 1921. Unfilled orders for locomotives increased to 2,316, a new high record.

The output of pneumatic tires and the consumption of crude rubber in February, which figures have just become available, were the highest on record since these statistics were established, in November, 1921.

Automobile shipments for March increased, and on the basis of shipment figures the total production of automobiles for March is estimated as 346,000 cars and trucks, the largest monthly production on record, being double that of March, 1922, and 25 per cent greater than February of this year.

The total value of building contracts awarded in 27 Northeastern States in March was $334,000,000, or about 14 per cent greater than a year ago.

The cost of building materials as represented by the Department of Labor index is still upward, while the labor shortage in the building trades is growing more acute.

Wheat movement for March was about the same as a year ago, but the visible supply was 28,000,000 bushels larger. The 1923 winter-wheat estimate of 572,000,000 bushels by the Department of Agriculture on April 1 points to the smallest crop since 1918. Prices of wheat and flour in general declined in March.

Freight-car loadings for March were not only the greatest on record for this season of the year but on a level not normally reached until about midsummer or early fall. As compared with a year ago, the March average loadings of ore were 150 per cent greater, while coal and forest products were upward of 40 per cent greater, indicating pronounced consumption of raw materials.

Byproduct Coke Output in March Reaches Unprecedented Total of 3,256,000 Tons

Production of byproduct coke in March, according to the U. S. Geological Survey, reached the unprecedented total of 3,256,000 net tons, which was 16 per cent greater than the February output and 5 per cent more than production in January. This total is based on early returns from all but one active plant and includes an estimate for one plant not heard from. The estimated present capacity of byproduct ovens is 3,725,000 tons per month of 31 days. Thus the output indicates production at the rate of 87.4 per cent of total capacity and an average of 105,042 tons per day, which is an increase of 4,692 tons, or 4.7 per cent, over the daily rate of production in February. Of the 71 plants in existence 64 were active and 7 idle.

Production of beehive coke continued on the increase in March and for the month totaled 2,759,000 net tons, an increase over February of 18 per cent. The March rate of beehive coke production was more than twice the monthly average for 1922, nearly four times the monthly average for 1921, and the same as the monthly average for 1920.

MONTHLY OUTPUT OF BYPRODUCT AND BEEHIVE COKE IN THE UNITED STATES (*a*)
(Net tons)

	Byproduct Coke	Beehive Coke	Total
1917 Monthly average	1,870,000	2,764,000	4,634,000
1918 Monthly average	2,166,000	2,540,000	4,706,000
1919 Monthly average	2,095,000	1,638,000	3,733,000
1920 Monthly average	2,565,000	1,748,000	4,313,000
1921 Monthly average	1,646,000	462,000	2,108,000
1922 Monthly average	2,374,000	669,000	3,043,000
January, 1923	3,100,000	1,478,000	4,578,000
February, 1923	2,810,000	1,482,000	4,292,000
March, 1923	3,256,000	1,749,000	5,005,000

(*a*) Excludes screenings and breeze.

The coal required for coke production in March is estimated at 7,438,000 net tons, which is more than was consumed by the coke industry in the War years 1917-1918 and is 17 per cent more than the average in the active business year 1920.

ESTIMATED MONTHLY CONSUMPTION OF COAL FOR MANUFACTURE OF COKE (*a*)
(In Net Tons)

	Consumed in Byproduct Ovens	Consumed in Beehive Ovens	Total Coal Consumed
1917 Monthly average	2,625,000	4,354,000	6,979,000
1918 Monthly average	3,072,000	4,014,000	7,086,000
1919 Monthly average	2,988,000	2,478,000	5,466,000
1920 Monthly average	3,684,000	2,665,000	6,349,000
1921 Monthly average	2,401,000	706,000	3,107,000
1922 Monthly average	3,411,000	1,056,000	4,467,000
January, 1923	4,454,000	2,331,000	6,785,000
February, 1923	4,037,000	2,339,000	6,376,000
March, 1923	4,679,000	2,759,000	7,438,000

(*a*) Assuming a yield in merchantable coke of 69.6 per cent of the coal charged in byproduct ovens, and 63.4 per cent in beehive ovens.

A Report on Corporate Relationships in the anthracite industry is to be made for the U. S. Coal Commission by Prof. George E. Barnett, of Johns Hopkins University. Professor Barnett is an economist, who has made a careful study of many matters of finance and is the author of various books on banking and on labor relationships.

Keeney, Mooney and Blizzard Trials to Be Held at Lewisburg May 9

Although Harold W. Houston, counsel for C. Frank Keeney, president of District 17, United Mine Workers; Fred Mooney, secretary-treasurer of District 17, and William Blizzard, vice president of subdistrict 2 of District 17, opposed it, Judge Woods in granting the request of counsel for the defense for a change of venue, designated Lewisburg, the county seat of Greenbrier County, as the place where the trio of officials should be tried, beginning May 9. All three are charged with complicity in the Logan armed march. Lewisburg is a city of about 1,200. Houston opposed Greenbrier County, contending that it was a non-union stronghold, although it is the center of an agricultural county. There are approximately 100 other defendants against whom charges are pending in connection with the Logan march whose status was not affected by the order of the court entered on April 18.

An effort was made to have the charges against Keeney dismissed on the ground that the time when Keeney might legally be tried had elapsed. Judge Woods overruled such a motion.

Confirms Payment of Damages by Union to Willis Branch Coal Co.

Judge George M. McClintic, of the U. S. District Court for the southern district of West Virginia, confirmed the report of the payment of a sum of money variously estimated at between $400,000 and $500,000, by the United Mine Workers to William McKell and others interested in the Willis Branch Coal Co. when in dismissing the suit against the miners' union in federal court on April 16 he stated that the union had paid an enormous sum in order to keep its activities from becoming a matter of public knowledge.

The suit instituted by the Willis Branch company against the union was for $1,000,000. An agreement was reached last February under the terms of which the union paid over a large sum of money to the company for the damage the union admitted had been done to the Willis Branch plant. This is said to be the first instance in which the union ever settled for overt acts of its members.

More than sixty union miners were indicted in connection with the shooting up of the town, eight of whom were convicted, and indictments are still hanging over many others. Among those implicated was David Robb, international financial agent of the United Mine Workers, who is said to have furnished $80,000 to the local near Willis Branch for furthering the reign of terror.

Dull Market in Southwest Nearly Shuts Down the Field

An idea of the extent to which mines of Kansas, Arkansas, Oklahoma and Missouri were being closed because of lack of market as early as April 1 may be obtained from reports submitted by the Southwest Interstate Operators' Association to the U. S. Geological Survey.

The banner week of the winter for Kansas was that ending Jan. 13. In that week twenty-three companies reported that 82,876 tons of coal were produced in forty-six mines. For the week ending March 31 thirteen companies reported 43,509 tons from thirty-four mines. Reports from Missouri show the same week to have been the best of the winter in that state. Fourteen companies reported a production of 42,262 tons from twenty-five mines. The week ending March 31, reports were filed by eleven companies for seventeen mines. The production was 35,169 tons.

In Arkansas 14,630 tons of coal were taken by seventeen companies from twenty-three mines the week ending Oct. 7, 1922. In one week in December twenty-one companies reported 10,206 tons from twenty-eight mines. During the week ending March 31 only three companies filed reports, these for nine mines, with a production of 3,120 tons.

Eleven companies, operating fifteen mines in Oklahoma, reported a production of 23,652 tons for the week ending Nov. 4, 1922. For the weeks ending Feb. 17 and Feb. 24, this year, twelve companies reported on sixteen mines. The tonnage was 23,288 and 17,316 for the respective weeks. Eight companies were operating nine mines the week ending March 31, and that week produced 7,493 tons.

The week of March 31 was chosen for comparison as representing the last week of normally maximum production. The reports show that even before the usual spring shutdown, lack of market was forcing a big proportion of the mines of the southwestern district to close. The same report to the Geological Survey shows that 55 per cent of mining time was lost in the Kansas field that week. Twenty-nine per cent of this was lost because of no market. Missouri mines lost 26 per cent time. Of this total, 92 per cent was because of no market. Four-fifths of the 59 per cent of time lost in Arkansas that week was because of no market. And of 89 per cent time lost in Arkansas, 89 per cent was attributed to the same cause.

Wadleigh to Issue May 1 Stock Report

F. R. Wadleigh, Federal Fuel Distributor, is preparing to bring out another stock report, as of May 1. It had been his intention to wait until June 1 before taking another census of stocks, but developments of the last week are such that he believes that the public will be benefited by showing the situation at the beginning of May.

Due to the difficulty at this time in obtaining the attendance of a number of very busy coal operators at a meeting in Washington, Mr. Wadleigh is having each member of his advisory committee write him in detail his views as to procedure in his study of storage, transportation and collective selling. This survey which Mr. Wadleigh is conducting in his capacity as Federal Fuel Distributor is going forward rapidly.

So that the public utilities may be encouraged to continue the practice of last year in providing storage, Mr. Wadleigh has called upon J. W. Lieb, of the New York Edison Co., for suggestions as to the encouragement of this practice this year.

During the study of railway transportation which has been undertaken by the Department of Commerce, Mr. Wadleigh will act as liaison officer between the department and the car-service section of the American Railway Association.

Denies Coal Commission Found Basis for Gouging Charge Against Operators

The Bituminous Operators' Special Committee on April 18, gave out the following statement:

"A recently published press report stating that the U. S. Coal Commission had made a finding to the effect that bituminous-coal prices had been increased without any corresponding increase to the operators in the costs of coal production and that the operators were gouging the public, was today officially denied by the commission.

"E. E. Hunt, secretary of the commission, in a letter to Harry L. Gandy, executive secretary of the National Coal Association, official organization of the bituminous operators, stated that he had been instructed by the commission, in the absence of John Hays Hammond, its chairman, to advise the National Coal Association that the commission had made no statement or report 'upon which such recent press statements could be based.'"

DR. GEORGE S. RICE, chief coal technologist of the U. S. Bureau of Mines, has been authorized by Secretary of the Interior Work to visit Europe during the coming summer to make a study of European mine-safety methods and to gather information as to more efficient methods of operating coal mines. Dr. Rice will leave about May 1 and will visit all the leading European countries where coal mines are operated, including England, France, Germany, Czechoslovakia and Poland.

THE BITUMINOUS OPERATORS' SPECIAL COMMITTEE began moving its offices April 18 to Room 805, Southern Building, Washington, D. C., which hereafter will be the committee's headquarters.

Germany Buys British Coal

When the French occupied the Ruhr they cut off Germany's chief source of coal. The Germans turned to Great Britain for immediate supplies. By April 1 more than 250,000 tons of British coal had been bought by Germany. This photograph shows a cargo being unloaded from the steamer into barges at Hamburg. Any time in the past three months one looking from the upper floors of the Whitehall Building, on the lower tip of Manhattan Island, could have seen a similar sight, a cargo of British coal being unloaded into harbor lighters. The difference would have been that instead of a grab bucket, as at Hamburg, he would have seen a wheelbarrow at the Battery—so unaccustomed and unprepared are we for unloading cargo coal in New York Harbor.

British Columbia Tightens Safety Rules

As a result of recent fatal accidents in the Cassidy mine of the Granby Consolidated Mining, Smelting & Power Co., and the Wakesiah mine, of the Western Fuel Corporation of Canada, regulations under the Coal Mines Regulation Act have been announced by William Sloan, Minister of Mines of British Columbia.

They provide that "every percussive air drill used for the drilling of holes in coal shall be equipped with a water jet or spray, or other appliance equally efficient, to prevent the escape of coal dust. This jet or spray to be of a type approved by the inspector of mines"; that "the use of a compressed-air jet for forcibly removing accumulations of gas is strictly prohibited"; that "when accumulation of gas is being removed, the official in charge shall see that no person or persons or lights of any description are allowed on the return side of the gas being removed, except at such a distance that the gas thus removed shall have been so completely diffused that its percentage is at that point lower than that requiring withdrawal."

They further provide that "the term 'properly fenced,' as quoted in General Rule No. 6, shall mean a fence 4 ft. high built of not less than three boards, 1x6, spaced so as not to obstruct the ventilation and nailed securely to posts. Where there are no posts on the ribs, then the ends of the boards shall be hitched into the coal at least 3 in. and securely wedged." The rules also order that "all places fenced off as required under the terms of general and special rules shall have securely attached to such a fence in a conspicuous place a danger signal properly worded, with the lettering at least 4 in. high; the lettering to be stenciled in white on dark background, both to be of durable material that will not easily become obliterated."

In one of the accidents to which reference has been made the miner lost his life through disregarding a fence and entering a prohibited working. When he was found the boards were scattered and there appeared to be some doubt as to whether they had been in place when the workman, subsequently overcome by gas, left his partner. In the other fatality loss of life resulted in the course of removing gas by means of compressed air. The regulations, therefore, are designed to meet these two sets of conditions and to avert accidents having such origin.

E. B. CHASE, vice-president of the Berwind-White Coal Co., has suffered a nervous breakdown and will be compelled to drop all business affairs for several months.

DuBois Convention Votes Against Paying Officers' Salaries During Strike

It cost District No. 2, United Mine Workers, approximately $45,000 to determine whether or not to pay the officers and field workers of the union $15,000 for services rendered during the strike beginning April 1, 1922. A convention of delegates representing the 45,000 miners of the district was called at DuBois, Pa., on April 17. After almost four days of debate on the proposition the delegates almost unanimously went on record as opposed to paying for the period. This settles the controversy so far as the last strike is concerned and the matter of making a change in the constitution depriving officers of pay during strikes was left over until the next regular convention. In the matter of officers' expenses, an amendment to the constitution carried which provides that expenses of officials, organizers and board members shall be itemized each month and that a detailed printed form of such expenses be sent to each local in the district by the fifteenth of each month.

The trouble which led to the calling of this convention had its origin at the close of the strike late last year. During the strike, officers and field workers were said to be working without pay. Following the strike and the election of officers for the district it was charged that the officers and field workers collected their entire back pay. The constitution does not provide that officers' wages shall cease during a strike but it was the hope of the opponents of the administration that the constitution might be amended at this session to make provision for such cases in the future.

The crisis in the convention came when Delegate George Bassett, of South Fork, made a motion that the officers "not receive back pay for the two and one-half months at present." The wording of the motion raised the further question of bringing the matter to a head again, regardless of how it would be decided on a vote of the convention.

Richard Gilbert, district secretary of the union, declared against the motion on the ground that it would injure the credit of the union in that it specifically stated that the union refused to pay back salaries due officers. This aroused a bitter debate among officers and delegates. Officers generally agreed to abide by the vote of the convention. Vice-President James Mark made one of the strongest speeches of the convention, arguing that the officers are entitled to the pay as a matter of constitutional right.

Mr. Mark told why the salaries were suspended and the effect in the Somerset County field. He declared the refusal to pay the salaries would put the union in a peculiar position with the public and bitterly denounced the *Penn Central News*, published at Cresson, for agitating the matter and being responsible for the calling of the convention.

When motives were questioned, President Brophy defended the officers. "Personally," he said, "I have given my services for six years as president not for the pay which is in it but because I believe firmly in the principles of unionism and your organization. The others have done this too, and it is unfair to impugn their motives."

Shots Shatter Calm of West Kentucky Strike

A fusillade of shots fired April 19 at a small party of men coming out of the Pontiac Coal Co.'s mine near Madisonville, Ky., marked the first sign of violence in the strike of about 5,000 miners in three counties of the western Kentucky coal field. Nobody was injured though an automobile carrying the little party of mine men was struck. The riflemen kept out of sight. The strike, which began April 1 after the operators of Christian, Hopkins and Webster counties insisted upon a two years' continuance of the existing wage agreement instead of a one-year term, has run smoothly up to the present. The Circle City Coal Co.'s mine at Nebo surrendered two weeks ago and signed for one year and has been working regularly. One other mine, of the Hart Coal Corporation, has gone on an open-shop basis and has been getting out a few tons each day by the labor of officials and a handful of laborers, but generally speaking the three counties have been idle.

Anthracite Operators File Brief with Coal Commission On Handling of Recent Hard-Coal Emergency

The anthracite operators on April 21 filed with the U. S. Coal Commission a brief on the anthracite emergency of 1922-1923 and how it was handled. By statement, table and text the situation with respect to production and distribution is fully set forth. Supporting documents in the form of letters from state authorities with whom the Anthracite Distribution Committee came in contact testify to the good faith and helpfulness of the hard-coal operators.

Commenting on prices the report says:

"The Pennsylvania Fuel Commission and the state and federal distributors did not stop with their efforts to secure equal distribution but also undertook with the co-operation of the operators to protect the public against exorbitant prices and unfair practices. The Pennsylvania Fuel Commission fixed a price of $8.50 per gross ton at the mines as a maximum price for so-called domestic sizes of anthracite coal and, realizing that certain operators could not produce coal at this figure, designated a Fair Practices Committee to consider individual cases and determine what should be a fair maximum price for operators who could not produce at the $8.50 price. Over 98½ per cent of the industry co-operated with the committee and accepted the prices approved by this committee.

"The State Fuel Commission also effected an arrangement with retailers that the margin of cost for handling and delivering anthracite coal should not be above that prevailing in March, 1922, and the efforts to have this policy observed met with a large measure of success. The Governor of Pennsylvania subsequently ratified and adopted these activities of the Fuel Commission and the Fair Practices Committee, at the same time declaring the existence of 'a serious public emergency.'

"Subsequently the Pennsylvania Fuel Commission circulated among the State Fuel Administrators a list of producers comprehending 98½ per cent of the production of anthracite, which were co-operating with the commission, and the prices that each was to charge, together with a warning as follows:

> We wish to bring again to your attention that certain irresponsible individuals and firms are taking advantage of the existing shortage of anthracite coal to sell to the trade inferior qualities of coal consisting of a considerable extent of bone, slate and other impurities, in many cases requiring payment in advance of shipment, or sight draft against shipping documents, and disclaiming responsibility for the quality of coal supplied, and thus protecting themselves against claims, etc.
>
> In view of these facts, the Pennsylvania Fuel Commission urges and advises all distributors and retailers of anthracite coal to purchase their coal supplies exclusively from the producers named in the list issued by the commission or from such responsible agents as will give proper guarantees that the coal sold by them comes from such listed producers. Lists of these producers will be furnished on application to the Pennsylvania Fuel Commission.
>
> Distributors and retailers are most strongly urged to follow this advice and thus protect themselves and the consuming public against the fraudulent practices referred to.

"The commission thus attempted to confine trade to legitimate producers and dealers who were co-operating with it, in order that the public might be protected against the so-called outlaw and bootlegger. The willingness of some consumers and dealers to disregard this warning in order to secure coal of any quality at any price, was the cause of the few irregularities which were so greatly magnified, but even under these circumstances the regular operator kept his record clean."

The Committee on Distribution had the co-operation of 85 per cent of the total production and was able to furnish an accurate check and supervision on the weekly distribution of this production to some 20,000 communities. Reports were furnished to each state administrator, showing the amount of coal shipped to each community under his jurisdiction the previous year, the 60 per cent allotment for the pending season, and the amount shipped during the week covered by the report, so that he could determine the total amount shipped for the season to the end of the week covered by the report.

With the exceptions noted, the co-operation of the anthracite producing companies in the work of the committee has been unique, if not without parallel in industrial history, and the work of distribution, it is believed by the operations, has been as nearly 100 per cent perfect as it was possible to make it, labor, transportation and weather conditions being considered.

Concluding, the statement says:

"As a record of self-restraint and moderation on the part of an unregulated industry, we submit this is unsurpassed. In the face of a buyers' panic and considerable hysteria which made the supply of coal and not the price of coal the first consideration of most consumers, with few exceptions this vast tonnage was produced and sold at prices which in the public interest defied the law of supply and demand.

"The opportunities for graft, profiteering, adulteration and corruption in many forms offered temptations to which too large a percentage of people often yield, but the record of this industry, so far as the legitimate producers of 98 per cent of the nation's supply is concerned, is remarkably clear.

"These operators have also co-operated in efforts to stop the shipment of so-called 'fireproof' coal. The Fuel Distributor stationed an engineer of the Bureau of Mines in the anthracite fields to secure evidence as to shipments of unmerchantable coal and it is noteworthy that the list of thirty-three different names found by him to have been guilty of this reprehensible practice does not contain the name of a real coal operator. They are merely dishonest speculators, who came temporarily into action for the purpose of fattening on public misfortune. A number of the names are but different disguises for a single headquarters. We doubt if the entire group of legitimate operators ever heard of any one of these concerns as engaged in the coal industry. For all normal purposes they are non-existent in the coal trade.

"It is submitted that even government is not proof against some corruption and favoritism and has been notoriously incapable of overriding economic laws. We contend, therefore, that no form of government control would have served the public better during the recent emergency than did the voluntary co-operation of the operators.

"The general strike described by the United Mine Workers as 'the greatest industrial dislocation in the history of the world' and which brought about the emergency with its train of economic derangements and opportunities for exploitation, may well call for regulation which will prevent repetition, but the minor evils which grew out of that derangement will disappear when the major problem of industrial warfare is brought under control."

D. & H. Celebrates 100th Birthday

Dim lights, Old Glory waving in the spotlight, a huge "birthday cake" with 100 candles, music, 500 guests and some speeches, too, marked the Delaware & Hudson R.R. centennial celebration at the Hotel Astor, in New York City, on April 23, 1923. E. H. Outerbridge, chairman of the Port Authority of New York and a member of the board of managers of the D. & H., presided. L. F. Loree, president of the Delaware & Hudson, the first speaker, attacked regulation of railroads and commissions in general as forms of "sham legislation." He was followed by James S. Alexander, president of the National Bank of Commerce, who in the course of his address defended regulation as a necessity, although he decried the direction it had taken in certain quarters.

H. W. Dickinson, of the Science Museum of London and secretary of the Newcomer Society, the guest in this country of the D. & H., was the last speaker. He traced the development of steam power from the earliest time to the first practical locomotive and Robert Fulton's steamboat.

British Coal Awaiting Shipment Inland from Hamburg

British coal is helping save the day in Germany, since France is taking all the Ruhr output. This picture of a corner in Hamburg harbor shows some of the British coal Germany is getting. So active has the demand for British coal become that the prices have risen 40 per cent in three months.

Navy Department Awards Contracts for 653,000 Tons of Coal

The Navy Department has awarded contracts for 653,000 tons of bituminous coal. Accepting tenders for coal for Hampton Roads when the quotation did not exceed $7 a ton, the Navy was not quite able to fill all of its anticipated requirements. Officials announced, however, that the remaining 100,000 tons would be bought on the open market during the next fiscal year, as it was believed that savings could be effected by purchasing "distress" coal when the opportunity presented itself.

Coleman & Co. was awarded the New York contract for 12,000 tons, the prices for the three classes being $7.27, $7.52 and $8.22 a ton.

W. L. Irish & Co. was awarded the Philadelphia contract, its prices for coal in barges under chutes being $7.33 and $7.51 for delivery in lighters free alongside.

The coal contract at Hampton Roads was distributed between four companies. Castner, Curran & Bullitt was awarded contract for 100,000 tons of coal to be delivered into storage at Sewalls Point, the price being $6.68, while the Fayette Smokeless Fuel Co. will supply 30,000 tons at $6.72.

For delivery at Lamberts Point piers, the Navy contracted to buy 408,000 tons. The Pocahontas Fuel Co. will supply 200,000 tons at $6.72, the Fayette Smokeless Fuel Co. 108 000 tons at $6.72 and the Crozer-Pocahontas Coal Co. 100,000 tons at $6.50.

The Navy desired to buy 200,000 tons of coal for storage at Sewalls Point.

Eleven proposals were submitted, as follows:

Twelve thousand tons, for delivery at New York between May 1, 1923, and June 30, 1924—Coleman & Co., Inc., Philadelphia, delivered f.o.b. vessels under chutes at piers, $7.27 per ton; delivered f.o.b. barges alongside vessels in New York harbor or at Brooklyn, Navy Yard, $7.52; delivered in lighters in New York harbor, $8.22; additional charge for coaling in regular bunkers 70c. per ton; in side bunkers, 80c. per ton; furnished f.a.s. government vessels, $8.72 in lots of less than 100 tons; $7.82 in lots between 101 and 200 tons; $7.62 in lots between 201 and 300 tons; $7.57 in lots between 301 and 400 tons; $7.52 in lots of over 400 tons; additional charge for delivery, $40 per lighter at all North River points. Imperial Coal Corporation, New York, $6.69 delivered f.o.b. vessels under chutes at piers.

Three thousand tons, for delivery at Philadelphia from July 1, 1923, to June 30, 1924—Imperial Coal Corporation: Delivered f.o.b. vessels under chutes at piers, $6.22 per ton; alternate bid, $6.49. W. L. Irish & Co., Inc., Philadelphia, delivered f.o.b. vessels under chutes at piers, $7.33 per ton; delivered in lighters, f.a.s. wharf at Navy Yard, $7.51 per ton.

Four hundred and twenty-five thousand tons, for delivery at Hampton Roads, Va., between July 1, 1923, and June 30, 1924—Crozer-Pocahontas Co., Philadelphia, 100,000 tons at $6.50. Fayette Smokeless Fuel Co., Mount Hope, W. Va., 108,000 tons at $6.72. Low Volatile Consolidated Coal Co., Beckley, W. Va.: 200,000 tons in all, 100,000 at $7.28 and 100,000 at $7. Pocahontas Fuel Co., Inc., New York, 200,000 tons at $6.72. White Oak Coal Co., Macdonald, W. Va., 72,000 tons at $7.

Two hundred thousand tons for delivery f.o.b. cars into storage at Sewalls Point, Va. Castner, Curran & Bullitt Co., Inc., New York, 100,000 tons at $6.68. Chesapeake & Ohio Coal & Coke Co., New York, 10,000 tons at $4.48. Fayette Smokeless Fuel Co., 30,000 tons at $6.72.

Lewis Confers with British Mine Leaders

John L. Lewis, president of the United Mine Workers of America, had a conference April 24 with Frank Hodges, secretary of the Coal Miners Federation of Great Britain. Details of the parley were withheld. The secrecy that has surrounded Lewis' conferences with British miners' leaders has led to the conclusion that some understanding is under consideration. Lewis arrived in London by airplane from Paris, April 23, following a miners' conference in Brussels, where the allied countries and Germany were represented. Lewis would not confirm or deny the report of a move to bring about a closer affiliation of the several miners' organizations, particularly between the American and British.

Southern Indiana Coal Fields Developing

Development of the coal fields in the southern part of Indiana is progressing at a rapid rate and just now it seems that that section lying between Terre Haute and Evansville, on the Evansville, Indianapolis & Terre Haute R.R., has prospects of becoming one of the most productive sections in the state. Improvements being made on this railroad, which is now operated by the Big Four, is going hand in hand with the development of the coal fields.

Between Petersburg and Evansville activity is greatest. The new Gray stripping operations at Oakland City with a capacity of 90 cars a day will start loading coal before long. The Enos strip mine at Oakland City recently added another shovel, which will raise its capacity from 65 cars per day to 100 cars. The Pike County Coal Co.'s new mine at Petersburg has reached a capacity of 25 cars a day and has tipple capacity of 75 cars daily, which it expects to reach by July 1. Pike County mine No. 1, at Petersburg, which has been in operation several months, recently spent about $75,000 in increasing its tipple capacity, which gives it a capacity of 75 cars a day.

The General Fuel Corporation mine No. 1, which started operations about Sept. 1, is hoisting about 22 cars daily and it is expected that this mine will be loading 50 cars a day by July 1. The No. 2 mine, which started hoisting Nov. 15, has a tipple capacity of 75 cars daily, which it expects to reach the latter part of this year. This mine, however, is loading, while under development, five cars a day. The Francisco mine, near Oakland City, started Sept. 1 and is loading 20 cars a day. It expects to reach its tipple capacity of 75 cars a day by autumn.

Negotiations are under way, it is reported, for trackage to a large operation at Buckskin, which will open 5,000 acres of new coal at an output rate of 120 cars a day. Practically all of the coal land between Petersburg and Evansville has been taken over by various companies, all of which will be opened in the near future.

A number of smaller operations are being started between Terre Haute and Petersburg. The capacity of the mines on this road now in operation is 550 cars a day as compared with 125 when the Big Four took over the properties on March 1, 1920. Car supply on the Evansville, Indianapolis & Terre Haute R.R. for February was about 70 per cent of the demand, which is the best supply for several months. The line is being improved as to trackage and power.

Governor Marshall Decries "Holier Than Thou" Attitude Of Both Sides in Probe of Coal Industry

By Paul Wooton
Washington Correspondent of *Coal Age*

So much energy is being consumed by the separate branches of the coal industry in hurling brickbats at each other that it is apparent that there is apprehension on the part of at least certain members of the Coal Commission lest in the mêlée sight will be lost of the constructive suggestions which each factor in the industry is pledged to bring forward.

Hurling and dodging missiles require such close and constant attention that it tends to preclude study and research, each of which must be undertaken intensively if the intricate problems before the industry are to be solved. Each is held to be necessary to the exercise of the requisite amount of vision to meet the situation.

There is a feeling among many federal officials who may be described as disinterested but intelligent onlookers that advantage has been taken of the commission's invitations for information to submit much material for the benefit of the gallery. No one will be surprised if the commission should consider whether or not the request for future reports should be coupled with the suggestion that they be withheld from publication.

It is obvious that the commission is tiring of the ceaseless attempts to put the other fellow in the hole. It recognizes that each side has done things that cannot be justified. It wants to know more than anything else what the parties to these controversies intend to do to prevent the recurrence of unlawful acts and of acts which cause the public to suffer. Is the conflict irrepressible? Must it go on with increasing violence? These are questions which the commission would like to have answered.

Shows Pressing Need for Harmony

The commission evidently recognizes that there can be no solution if all one side does is to say that no one may work in a mine if he does not belong to the United Mine Workers of America. By the same token, the members recognize that it is no solution to advocate severance of all relations with the United Mine Workers. It is suggested that more constructive things must be forthcoming in the next ten years than has been the case during the last decade. During that period one side has striven to get rid of the miners' organization while the other has bent every energy to unionize all mines. It is believed to be the thought of the commission that some suggestions should be brought out by those most at interest for a relationship promising a much greater degree of harmony. If they have no such suggestions and if they can offer no solution for the existing intolerable relationship, it is certain that the commission would welcome a frank acknowledgment to that effect. In such an *impasse* the government, as a representative of the public, will have to try its hand in an effort to bring about a better functioning of the industry.

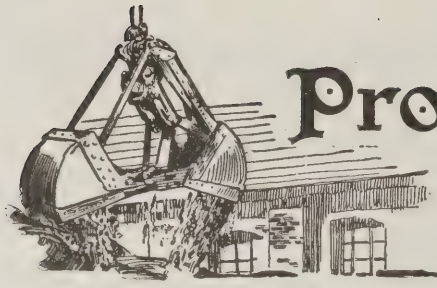
It is the plan of the commission not to make public at this time the material obtained in the report made by W. Jett Lauck in connection with the anthracite situation. Governor Marshall stated on Saturday that he has made digests of records of courts and of the reports of government agencies, such as the Federal Trade Commission, the Interstate Commerce Commission and the Geological Survey. Mr. Lauck's report, setting forth what he says are deductions of fact from these documents, is being submitted to the anthracite operators. They will be given an opportunity to take issue with any statement made in the report. The commission is not accepting as facts any statements, government or otherwise. If anything purporting to be a fact is questioned, it is only common justice, Governor Marshall pointed out, to hear testimony on it.

During Saturday's hearing Governor Marshall urged the representatives of the press to be constructive in their articles on the coal situation. It is a question in which the public is vitally interested, he said, and this interest should be rewarded by an opportunity to get the real facts as to the situation in the coal industry. He stated that he is not annoyed by articles that reflect adversely on the commission. Throughout his own career, he said, his chief concern had not been with the untruthful things that newspapers said about him but fear that they might learn, and print, the truth about him. He described the newspaper of today as "the moving picture of a restless age," and fault should not be found with what the camera catches. In the course of his conversation with the newspaper men Governor Marshall said:

"When this investigation began, we were assured by everyone who had a right to speak, or who said they had a right to speak, that they would bend their energies toward assisting the commission with constructive suggestions looking to peace in the industry, justice to all concerned, and to the continuity of employment, output and distribution.

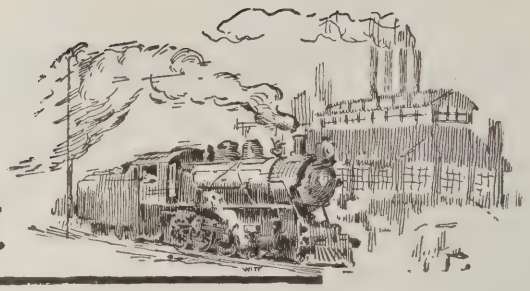
"I have no reason to believe there is any change in that purpose but I am a little bit alarmed as to whether or not the recent efforts to disclose the past history of the industry has not resolved itself into attempts to show that one side is without reproach and the other without virtue. Of course, no criticism can be offered justly against the pleading of a man's cause. The past has to be determined to reach any conclusion as to how past conduct should be changed in order to help the future, but I hope their promise to the commission is to be kept. After they have cussed each other out, I hope they then will be willing, during the life of the commission, to meet in a friendly way and assist in the formulation of such changes as will bring about not only better understanding and better feeling but which will be conducive to the good of the American people."

New Questionnaire Goes to Wholesalers



The wholesale section of the U. S. Coal Commission has prepared and sent out to wholesale coal dealers a new questionnaire designated as Form R-40 dealing with investments, profits, etc., of sales agents and wholesalers of coal. The questionnaire is quite elaborate, consisting of seven pages, in which information for the past ten years is requested as follows:

(1) Detailed information for classification of company.
(2) Data as to organization.
(3 & 4) Profit and loss statement.
(5) Analysis of wholesale coal and coke operating expenses.
(6) Balance sheet.
(7) Reconciliation of surplus account and statement of notes outstanding.



The report on Form R-40 is required by the commission only from such operators as conduct a sales agency or wholesale business involving the sale of coal other than tonnage produced by their own mines.

The Bituminous Operators' Special Committee will send speakers to the farming sections of the country during the next few months to tell the farmers why the production of coal has been seriously hampered and why this cost has mounted higher and higher since the war.

Viscountess Rhondda, the only woman director of large coal fields in Wales and also the owner of vast estates in the Principality, is disposing of part of her Monmouthshire properties. The occupying tenants were given the first opportunity to purchase and already have bought their holdings to the value of £90,000.

Production and the Market

Weekly Review

Spot prices in general continue their declining tendency. Current prices are below contract figures in some areas, as Pittsburgh, by as much as 50c., thus reflecting a normal situation for this time of year. *Coal Age* Index of spot prices of bituminous coal declined 4 points from 235 to 231 on April 23. The corresponding average price was $2.79. Buyers as well as producers appraise the outlook similarly, both calculating that as the summer passes into autumn, demand and price will mount. For the time being some buyers elect to enter the market and find steam coal available at around $2. At this price, on present wage scales, shippers are for the most part taking a loss and those who have no other outlet than the spot market are closing down their mines.

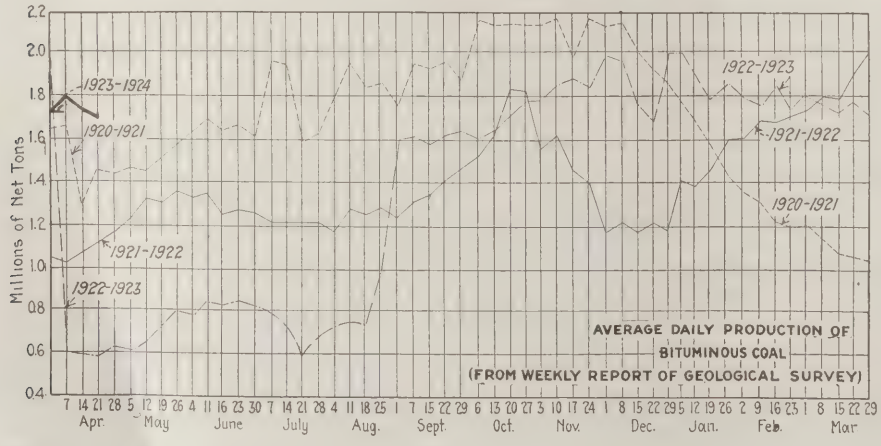
Typical of what is happening is the experience of one large company that during the severe car shortage period was obliged to prorate contract shipments. Adjoining operators without contracts were running, taking a share of the cars and selling on the spot market to the contract customers of the large producer. The spot market having fallen off, the intermittent mine is closed down, with cars of coal on demurrage, and the contract buyer is again getting all his coal where he originally bought it. Meanwhile the production in the district is practically unchanged.

Lake Movement Slowly Gaining

Present indications are that southern West Virginia non-union coal will maintain a commanding position for some time. Prices on the whole list are being well maintained and are such as will permit competition from all-rail central Pennsylvania steam coal, thus relieving, on the important New England market, a repetition of the strife of 1921.

The Lake season is slowly gathering momentum. Apparently, whatever tonnage of soft coal is wanted will be forthcoming, but on price there is no agreement generally between buyer and seller. Unless the unforeseen comes to pass, 1923 will be a comparatively light year for Eastern Lake shippers. Business is active in the Northwest, but so are coal shippers from the Middle West even as far south as Kentucky. All-rail competition has the Eastern coal-dock and coal-mine operator worried.

There is no disposition in the Middle West to run mines with prices below cost of production and many large properties and a host of small ones are already closed down. Steam-coal prices are below $2. Railroad fuel contracts have been closed at little above $2 on coals that commanded $2.50@$3 when the year began.



Export Market Quietly Expanding

The export market is quietly developing. France placed an order for high-volatile coal for delivery through the summer at $3.35 per net ton. Baltimore has been experiencing a revival in foreign coal trade, 174,283 tons of cargo and bunker having been loaded out in the first three weeks of April.

Final estimates of soft-coal production during the coal year 1922-1923 place the total at 418,734,000 net tons, according to the Geological Survey. This is a decrease of 21,783,000 net tons as compared with 1921-1922 and 115,006,000 net tons under the production of 1920-1921.

"The total soft coal raised in the week April 9-14," says the Geological Survey report, "including coal coked, local sales, and mine fuel, is estimated at 10,393,000 net tons, which is 764,000 tons more than in the short week preceding but is a slight decrease as compared with the week ended March 31. Preliminary reports of cars loaded in the week April 16-21 indicate decrease to between 10,000,000 and 10,200,000 tons."

Demand for anthracite domestic sizes continues brisk. Retail dealers are filling consumers' orders as rapidly

Estimates of Production

(Net Tons)

	1922	1923
BITUMINOUS		
March 31	10,469,000	10,430,000
April 7 (*b*)	3,835,000	9,629,000
April 14 (*a*)	3,656,000	10,393,000
Daily average	609,000	1,732,000
Calendar year	136,779,000	159,164,000
Daily av. cal. year	1,545,000	1,794,000
ANTHRACITE		
March 31	1,896,000	2,008,000
April 7	9,000	1,602,000
April 14	6,000	2,067,000
Calendar year	21,792,000	29,537,000
COKE		
April 7 (*b*)	175,000	428,000
April 14 (*a*)	140,000	420,000
Calendar year	2,123,000	5,557,000

(*r*) Subject to revision. (*b*) Revised from last report.

as they receive the coal and have not started to fill their yard bins. Steam sizes are beginning to accumulate, it being reported that some producers are sending part of their tonnage to storage. Production during the week ended April 14 is estimated at 2,067,000 net tons.

Most Midwest Trade Drags

The Midwest market for almost all coals is spongy indeed. Good domestic has been selling fairly well because of continued cold weather but spring appears to have come at last and even this trade is threatening to disappear for awhile until stocking business starts. Practically every middle- and small-size coal is in trouble. Southern Illinois screenings in Chicago have slumped under $2, central Illinois is suffering at $1.60 and there is no price at all on Standard district output. Indiana Fourth Vein is carried along by the fluctuations of southern Illinois. It is confidently expected that when domestic demand grows even softer within a week or two, steam sizes naturally will rescue themselves from these abnormal depths.

Household trade in anthracite and smokeless is fair, for there are a few far-sighted consumers in this region. Stove and furnace sizes of hard coal are offered by retailers at $15.50 and $16 now and Pocahontas mine-run at $9. A little easing up of rail congestion on coal from the East might drop these prices a shade but not much, for the opening of Lake traffic is expected to take enough cars out of long-haul service to make smokeless and Pennsylvania coals hard to get here.

St. Louis Does Little But Railway Business

Warm weather around St. Louis has practically stopped the spontaneous buying of cheap coal in small lots. Some coal is going into storage, however, because of price, which is $2 a ton less than it was thirty days ago. Mt. Olive deliveries are practically nothing, and Standard coal is moving slowly for domestic uses. Wagon-load steam has been good but carload steam shows a slowing up. Anthracite movement is fair. Coke and smokeless are dragging.

Railroad tonnage through this gateway has been easy for some time past. A little coal moves to the Northwest and some to Chicago.

West Kentucky Market Is Fair

Demand for western Kentucky coal while not heavy is fair, and prices are well maintained. Screenings are a little firmer and quotations for May delivery higher. Car

*Net tons, f.o.b. mines †Advances over previous week shown in **heavy type,** declines in *italics*

Coal Age Index 231, Week of April 23, 1923. Average spot price for same period $2.79. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

supply is 99 per cent on the Illinois Central, 60 per cent on the Henderson division of the Louisville & Nashville, and 37 per cent on the Owensboro division. Much new equipment and many mechanical coal loaders are going into this field to help meet Eastern competition.

Louisville Trade Is Awake

In Louisville trade is fair considering the facts that Lake movement hasn't opened much and that retail demand is slowing down. Prices are much higher than they were at this time last year. There is good demand from utilities, railroads scattered industries, steel and metal working plants and building-material producers. The brick and cement interests were never busier than they are now. Gas coal is in fair demand, as byproduct companies are busier and gas companies have worked down their stocks and are in the market again. River movement is awakening.

The price situation is practically at a deadlock. Operators assert that they are down to bedrock as a result of high union scales, and the fact that they are restricted to three days a week or less by car shortage and slow market.

Northwest in Lull Preceding Lake Season

The quiet before the storm would be an apt characterization of the market at the Head-of-the-Lakes at present. The market has dropped off with the advent of temperature above the freezing mark and everyone seems to be waiting to see which way the cat will jump after the opening of navigation. There are not more than 600,000 tons of bituminous coal on the docks now. Anthracite is exhausted, of course, and has begun to come in by rail to meet special needs. Hard coal by Lake is expected to start at $2 under last year.

Prices are firm. Screenings, of which there is a large amount, sell at $4.75, lump at $8.50 and run of pile at $7.50. Pocahontas mine-run is quoted at $8.75 and screenings, mostly dust, at $7. There is a fair supply of coke and briquets, the former at $12 and the latter at $10.50.

Some Kentucky coal, traveling all rail, has reached the Duluth market and is competing. The differential in freight rates makes this possible.

Extreme dullness prevails in Milwaukee coal circles. Cheaper coal is expected when navigation opens. There is a steady influx of anthracite and soft coal by rail and car ferry, but not any more than enough to keep dealers supplied promptly. Prices continue unchanged. A revision of prices probably will be forthcoming May 1. Coke is due for a substantial drop.

Western Business Is Light to "Rotten!"

In Kansas City and the region supplied by the Kansas, Oklahoma and Arkansas coal fields coal trade for the past week has been light but some coal has been moving most of the time from operating mines because the number of mines constantly dwindles and retail prices are dropping. Governor Davis' investigation to determine whether the shutdowns are necessary or just for fun is still going on.

Coal business in Utah is described feelingly as "Rotten!" Mines are working less than two days a week. There is no contracting and dealers report domestic consumption at a low ebb. There is no business from the Coast. As a result of the low production the slack market is tightening up. Smelters are using more of this grade than they did, but in most cases they have large stocks on hand.

Columbus Market Develops Strength

Slightly more strength has developed in the Columbus market due to the falling off in supplies as a result of the closing down of mines and reduced car supply. Contracting for steam tonnage shows more activity. Buyers are showing some anxiety as to future stocks and are placing contracts around $2.35@$2.50 for mine-run. Railroad, municipal and school contracting is going on to some extent.

In the Cincinnati market more talk of quality coals was heard and coals with established reputations brought good money. Better grades of steam coals are in better demand because large buyers believe that at current prices this coal is a good "buy." The Cleveland market is dull. Buyers want to contract at current prices while sellers are not disposed to tie up their output at such figures as now prevail.

Mines in Pittsburgh District Close

There is a continuance of the tendency in the Pittsburgh district to close mines particularly dependent on the spot market for an outlet, as that market has meant a loss for several weeks. The market is suffering from the failure of the Lake market to open extensively. Both industrial and railroad consumption of coal is excellent, while the steel industry continues its best showing for steady and sustained production.

Some of the shippers in the Buffalo market say buying continues to fall off.

New England Price Tendency Higher This Year

The only developments of the week in New England disclose a purpose on the part of producers to maintain a higher level of prices than prevailed during 1922. Recent bids for Navy supply, particularly at Hampton Roads, have been closely analyzed by the trade, and the basis is practically a dollar a ton more than quotations were being made a year ago.

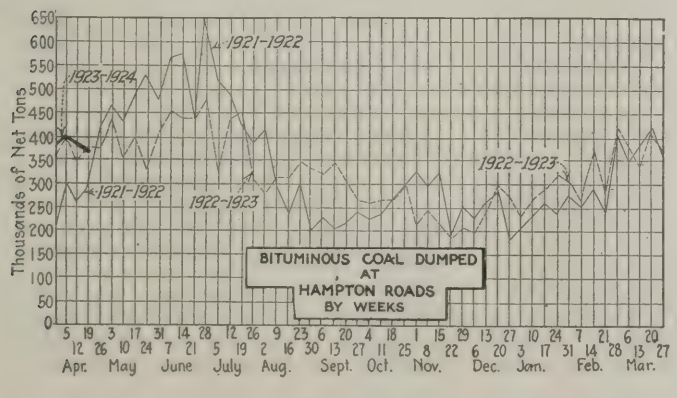
At Hampton Roads accumulations continue to about the same extent as for a month past, but quotations are not enough easier to justify predictions of a soft market later on. The agencies are proceeding on a month-to-month

basis as to price, and, for the present, notwithstanding the Navy bids, buyer and seller are not likely to agree on a season base price. For distribution inland from Boston, Providence and Portland $8.25 per gross ton on cars is about the current figure. There are still delays at railroad berths, but they are by no means as serious as during March.

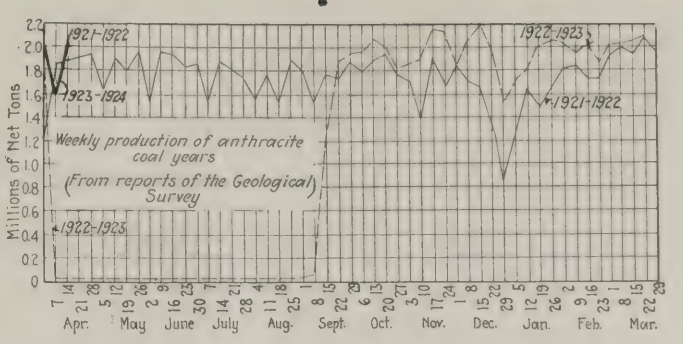
Buying is cautious and there are few intimations of any comprehensive purchases the next fortnight or so. Railroads have made purchases but along much restricted lines, and to the trade it was no surprise to see a large order placed in the usual channels. Less is heard from Scotch and Welsh high volatiles, and arrivals from British ports are likely to be few and far between during the balance of the season.

Sales agents for coals in the Pennsylvania districts are under more and more pressure to get business either spot or contract, and in consequence prices have reached a low ebb. It is nothing unusual now to have fair grades of Clearfield offered at around $2.25 per net ton at the mines, with better grades running up to $3 and $3.25. The really choice coals are still in position to command $3.25@$4 but most of these are specialties, and in some cases operators are finding it difficult to move current output. A small tonnage found its way to shoal points along the cost, where freight rates from Philadelphia as compared with Hampton Roads are slightly in favor of Philadelphia loading, but in the aggregate the tonnage was not large and not especially significant.

For the bulk of their market Pennsylvania operators must still look to the all-rail route, as far as New England is concerned, and if Pocahontas and New River are to be maintained a dollar or so above last year it is quite possible there will be an enlarged outlet for the better grades from Pennsylvania later in the season. It was the $6 or less price on cars at Boston a year ago that put all-rail coals into the discard for large sections of this territory.



New York Dealers See Bottom of Market



Some dealers in the New York market believe the bottom has been reached in prices and while demand continued slow last week there were numerous inquiries. It is said that a few large consumers had made heavy purchases. Philadelphia buyers on the other hand, do not seem to think the bottom has yet been reached. There is a general intention on their part to stock up when they consider the low point has been reached. The soft-coal market at Baltimore was soft, the export movement being the feature of the situation.

Steam Inquiry at Birmingham Disappoints

Inquiry for steam coal at Birmingham, Ala., was not as brisk as was desired. Railroads which use upward of one-third of the total annual production of the field are preparing to negotiate new contracts.

While there has been some buying for Lake shipment, the market has not opened extensively. Heavy ice is reported from various points and unhampered traffic is not expected until the end of the first week in May. During the week ended April 23 soft coal dumped at Lake Erie piers totaled 236,611 tons of cargo coal and 9,791 tons of fuel coal, making a total of 640,118 tons of cargo coal and 26,897 tons of fuel coal dumped this month.

Domestic Anthracite Active; Steam Dull

The demand for domestic sizes of anthracite is active. Retail dealers books are filled with orders. Steam sizes are causing some trouble because of the lack of demand.

"Production of anthracite recovered promptly from the depression due to holidays and again passed the 2,000,000-ton mark," says the Geological Survey. "The total output in the week ended April 14, including mine fuel, dredge and washery coal, and sales to the local trade, is estimated at 2,067,000 net tons. This was an increase of 465,000 tons over production in the holiday week preceding and was 59,000 tons more than the output in the week ended March 31. The cumulative output during the present calendar year to date stands at 29,537,000 tons, an increase of 7,745,000 tons, or 36 per cent, over the corresponding period in 1922."

Beehive Coke Output Declines Slightly

"The production of beehive coke declined slightly during the second week of April," the Geological Survey reports. "Using as a basis the number of cars loaded by the principal coke carriers the total output was estimated at 420,000 net tons, against 428,000 tons in the week preceding. The decrease was general except in West Virginia, where there was an increase of approximately 3,000 tons."

How the Coal Fields Are Working

Percentages of full-time operation of bituminous coal mines, by fields, as reported by the U. S. Geological Survey in Table V of the Weekly Report.

Foreign Market And Export News

British Mines Heavily Booked with Orders—Production Shows Further Cut

Output of Great Britain's coal mines during the week ended April 7 was 3,940,000 tons, says a cable to *Coal Age*. This is a decrease of 934,000 tons, when compared with the production of the previous week which was 4,874,000 tons. The week of April 7 included a national holiday, Easter Monday. The cutting of production made the scarcity of Welsh coal more pronounced.

About 46,000 men, or one-fifth of the men employed in the Welsh coal fields were involved in the recent strike, the object of which was to force the surface men, who have their own union, into the Miners' Federation. The men are now back at work, and the surface men continue to be independent of the Federation.

Over one-half of the present Welsh exports are going to France and Italy, but the exports to South America, coaling depots, the Far East, Belgium, and Germany are on a satisfactory scale.

Mines are booked with orders to the limit of their capacity. It is believed that if increased supplies were available the export coal trade would now be able to surpass the high level attained in former record years. Scarcity of supplies, however, acts as a deterrent to further export expansion. Mines in the Newcastle district are sold up well into **May.**

Coal exports officially reported from London for the weeks ended April 13 and April 20, in tons, follows:

	April 13	April 20
South Wales district	.....	2,647
Newcastle (Tyne) district	1,140	1,020
Clyde	4,700	.....

French Mine Strike Settled

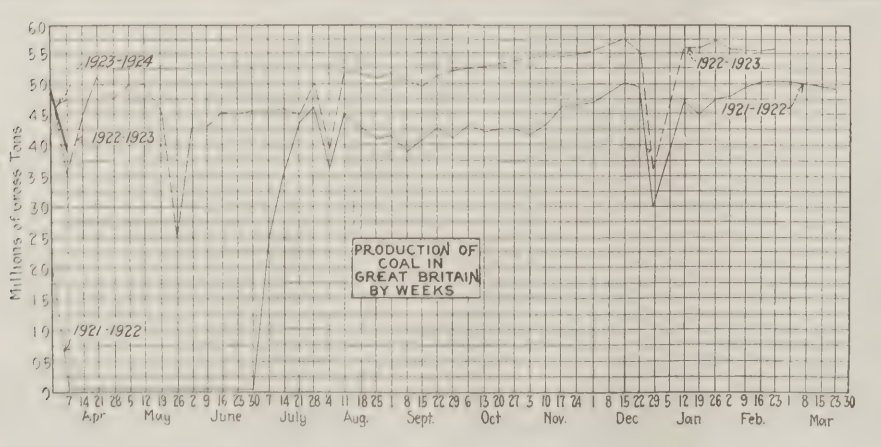
The strike that was in progress in the Lorraine coal fields for several weeks was settled early this month, work being entirely resumed in the mines on April 6. The settlement it was hoped would hasten similar action in the Saar region where the workers have been on strike for some time.

Demand for industrial coals continues heavy and consumers' supplies are low. The transportation difficulties which were mostly due to congestion at French sea ports owing to heavy imports of British coals have been much relieved. In the Loire and Center coal fields, the shortage of coals is none the less acute than in the north of France, and small collieries which usually have difficulty in selling their product are sold up.

The following bids for supplying coal to the Prefecture de la Seine have recently been accepted:

Eighteen thousand four hundred tons of half-fat run-of-mine, tendered by the Cie des Mines d'Aniche at 102 fr. 50 f.o.b. mines;

Ten thousand tons of anthracite (lean) cobbles, tendered by the Cie des Mines d'Anzin at 148 fr. f.o.b. mines.



Shipments of coke amounting to about 2,700 tons were made daily to France from the Ruhr toward the end of the first week in April. It was expected that this tonnage would gradually increase.

Business at Hampton Roads Brisk

Business was brisk at Hampton Roads last week, with prices stronger and inquiries and demand on the upgrade. Export business fell off but bunkers held good and coastwise shipments were fair.

Accumulations at the piers increased, as a result of an improvement in the car situation, which was about 60 to 70 per cent of normal. The demand, however, was sufficient to guarantee against demurrage.

Domestic dealers watched their business drop, because of the advent of summer, but were devoting their energies to launching the summer's ice business. The general tone of the market was firm, and the outlook for a good business during the spring and summer was favorable. Shipments to France continue in small quantities, with prospect of increasing.

Saar Production, 1922

During 1922 the Saar collieries produced 11,240,000 tons of coal and 253,120 tons of coke. The coal produced was distributed as follows:

	Tons
Mines' consumption (with annexed works)	813,837
Supplies to mine workers	347,762
Delivered to coke ovens	317,702
Shipments on sales	10,207,773
Total	11,687,074
Less: decrease of stocks during the year	447,071
Output	11,240,003

News Items From Field and Trade

ALABAMA

At a recent meeting of the stockholders of the **Burnwell Coal Mining Co., the capital stock was increased from $200,000 to $250,000.** The company operates commercial mines in Walker County, with principal offices in Birmingham.

The Porter Coal Co. has been incorporated with a capital stock of $10,000 and will take over the operation of the Porter Mine in Walker County, near Palos. K. E. Cooper, Sumner E. Thomas and Brewer Dixon, of Birmingham, are the incorporators, Mr. Cooper being president of the company.

The Alabama Company will soon be producing coal from its No. 2 mine at Lewisburg, Ala. This mine has been developed for several years but has not been operated for some time, but due to the company's pressing need for coal it has been decided to place the mine in operation.

J. J. Forbes, mining engineer in charge of the Birmingham station of the Bureau of Mines, **has been detailed with the U. S. Coal Commission to collect data** on coal losses in mines in the southern district. Dr. F. B. Meriwether, surgeon, Bureau of Mines, also is in the district assembling data on camp sanitation for the use of the Coal Commission.

ALASKA

So as to make more available the coal resources of the Moose Creek field, the Alaskan Engineering Commission has cabled the Secretary of the Interior, recommending the **immediate construction of a spur into the Moose Creek field.** W. P. T. Hill, of the Bureau of Mines' staff, who has been studying the situation in this coal field, reports that development has reached a point where the building of this spur is justified by the prospective tonnage.

COLORADO

Judge T. Blake Kennedy, of the U. S. District Court at Denver, on April 6, **issued a temporary injunction setting forth in detail the policy to be adopted by the Denver & Salt Lake R.R. in allocating cars to coal mines.** The injunction was issued on the application of the Interstate Commerce Commission in proceedings instituted on behalf of several other coal mines on the route which alleged that in assigning cars to the mines the railroad company had not taken into consideration those cars supplied to mines for the transportation of coal destined for the use of the railroad itself.

ILLINOIS

The No. 4 mine of the **Gartside Coal Co.,** at Murphysboro; the Tilden **mine** of the **Madison Coal Corporation** and the mine operated by the **Union Fuel Co. at Auburn** have been temporarily closed.

Pumps have been started at **the mine of the Kanawha Fuel Co. at Duquoin.** While no reports have been given out, **it is generally supposed that the mine is to be opened soon** either by the owners or under lease by another concern. The mine has been operated until about a year and a half ago by the Old Abe Mining Co., which is controlled by the same officials as the Kanawha Fuel Co., of Milwaukee, Wis. If the mine is opened much new machinery and equipment will have to be installed to take the place of that removed or destroyed by water since the plant was shut down.

The Coal Operators' Association of the Fifth and Ninth Districts of Illinois, including the operators of 99 mines in southern Illinois adjacent to St. Louis, has decided to **protest against the passage of a bill** pending before the Legislature **which provides for a tax of 8c. a ton on coal** as it comes from the mine. The tax, if placed, would be an additional cost to the consumer and besides would handicap the industry in Illinois in competition with other coal fields, according to Dr. C. H. Krause, president of the association and vice-president of the Willis Coal & Mining Co. The association will also oppose a bill which will put the regulation of the coal mines under the jurisdiction of the Commerce Commission.

The mines of the **Superior Coal Co. broke all its own weekly** records in the last week of March when the four mines hoisted a total of 117,242 tons of coal for the six days. Thursday of that week the four mines hoisted 20,191 tons of coal, the greatest tonnage ever hoisted in a day of eight hours by the four mines. The average daily hoist for the week was 19,540 tons. On Thursday, March 22, mine No. 2 broke its old record for tonnage and also established a new company record for mine cars hoisted in eight hours, by hoisting 1,648 mine cars with a tonnage of 5,625. T. T. Ferguson is the manager of the mine and William Harlow and Emil Viehweg are the engineers who made the hoist, working alternately one hour apiece.

On Thursday, April 12, **No. 6 mine of the Peabody Coal Co. made a record hoist** of 2,830 tons with a time loss of 23 minutes. The previous record at this mine was made on Feb. 24, 1919, when the tonnage raised was 2,667. The mine is in charge of P. W. MacMurdo, superintendent, and Owen Melkush, manager.

The following **mines in the Belleville district have been temporarily closed:** Columbia Colliery Co., Famous Mine at Freeburg and Royal Mine, Belleville; Star Coal Co. at Freeburg; B. & B. Coal Co. at Belleville; Signal Hill Coal Co. at Belleville; Summitt Coal Co., at Belleville; Fullerton Coal Co., at Belleville. Other mines closed recently are the Consolidated Coal Co.'s West mine at Breese and two mines operated by the O'Gara Coal Co. in Saline County.

There are two coal companies prospecting in Fulton County, one of which, the **Tiger Coal Co., is laying a switch** for a strip proposition.

The Colonial Collieries Co., 38 South Dearborn Street, Chicago, has incorporated with a capital stock of $500,000. Incorporators are Thomas J. Mylet, Edward G. Sternberg and Herbert Lanigan. The purpose is to mine, transport and sell coal.

F. W. J. Sextro, formerly officer and director of Rutledge & Taylor Coal Co. and Security Coal & Mining Co., **has acquired the Paramount Fuel Co.,** Chicago. Effective at once, Mr. Sextro will be actively associated with this company at 607 Fisher Building.

Charles C. Fitzmorris, recently Chief of Police of Chicago, who retired with the Thompson administration at the last election, **has been made president of the Eureka Coal & Dock Co. of Chicago.**

Paul Weir, for the past two years chief engineer of the Bell & Zoller Mining Co. properties at Zeigler, has just been appointed to the position of general superintendent over the same property. The promotion was a surprise to all, including Mr. Weir himself.

INDIANA

The Conveyors Corporation of America, Chicago, announces the appointment of **Irvin C. De Haven Engineering Corporation,** State Life Building, Indianapolis, as district representative. The new agency will handle the sale of the American steam jet ash conveyor in Indianapolis and surrounding territory.

Indiana miners will pay the lowest price for their powder for the next year of any district in the country and will save approximately $80,000 during that period, as a result of a contract signed by committees from the Indiana Bituminous Coal Operators' Association and United Mine Workers. Last year's price of $2.10 a keg is reduced to $2. According to the Terre Haute agreement, the coal operators of this state are to furnish black powder to the miner at cost, plus the expense of handling, transportation and insurance. These expenses were fixed at 25c. a keg and a reduction in the cost of the black powder from $1.85 to $1.75 brought the reduction in the price to miner. The contract dates from April 1, 1923, to April 1, 1924.

The Akin-Burton Coal Co., of Terre Haute, has incorporated to produce and sell coal. Charles T. Akin, Sedgwick R. Akin and Charles E. Burton are the incorporators. The capital stock is $50,000.

Retail coal prices in Indianapolis have declined about $1.50 a ton on all grades the last few weeks, a survey of prices shows. Summer schedules usually are issued after the middle of April, and a further decline is expected when these schedules are fixed. Pocahontas lump, which hit the high mark of $13 to $13.25 a ton in the winter, can be bought now at prices generally ranging from $11 to $11.50 a ton, though some firms are charging $12. Indiana fourth vein lump is quoted as low as $5.95 a ton. In the winter it was as high as $7.50 to $8. West Virginia and Kentucky domestic sizes are $9 to $10 a ton, a decline of about $1.50. The break in prices began about three weeks ago.

Work in the Atlas mines, at Petersburg, has been resumed following a brief strike of the machine operators which was settled by arbitration. The machine operators complained that the scale paid did not recompense them for cutting entries in the mine, as the Atlas mine is driving entries only during the summer months and the machine operators cannot make as much as they did formerly by cutting coal in rooms in which it is not necessary to move their machines so often. The Howe Coulter Coal Co., operating the Atlas mines, and the union reached an agreement whereby the coal company will be enabled to drive entries all summer and when the coal business is resumed next autumn 750 men can be placed in the mine, instead of the 500 now employed. Coal mines in Pike County are operating less than 40 per cent. Only the stripping mines are operating full time.

KANSAS

Governor Davis has been asked by the district miners' union at Pittsburg, **to require the Jackson-Walker Coal & Mining Co. to resume operations** at its No. 16 mine. It was asserted by the officials of the company that the mine had been shut down since March 28 because of inactive market

KENTUCKY

General offices for the development of the new Henry Ford properties in Kentucky will be at Stone, nine miles north of Williamson, in Pike County, on the Kentucky-West Virginia border. Stone has a population of 503 persons. This announcement was received by the Lexington Board of Commerce, which had been endeavoring to have the state offices located at Lexington.

The Elkhorn Coleman Coal Co., whose mine at Millard, Pike County, on the C. & O. Ry., was closed in May, 1921, reopened that operation in December last.

Elkhorn Marrowbone Coal Co., of Wolfpit, Pike County, on the C. & O. Ry., reopened their mine at that place in November last after being closed since May, 1921.

A report from Whitesburg, is to the effect that the **Consolidated Fuel Co.,** Pittsburgh, Pa., operating at Dalna, **has bought a large coal land acreage** near Livingston, in Rockcastle County, and is planning development.

The United Mine Workers, in a legal battle to collect $32,000 from the Mahan Jellico Coal Co. for alleged violation of contract, appealed April 18 at Frankfort from a decision of the Whitely Circuit Court that declared the wage agreement invalid. The miners contend that they signed in April, 1920, and that the company, after trying to get them to give up their union charter, closed the mine down in December, 1921, and refused to pay the miners the $2 a day provided in the agreement in case the mines were closed on account of any dispute and the company either failed to appear before an arbitration board or to abide by such a board's decision.

Terminal improvements under way or planned **in Louisville** for increasing car handling facilities of local yards **will cost about $8,000,000.** The Kentucky & Indiana Terminal R.R. has placed orders for several additional switch engines and has announced plans for a large increase in trackage. The C.C.C. & St.L. is planning to double track the Big Four bridge at Louisville. The Louisville & Nashville is building additional yards south of the city. Contracts for heavy car repairs have been placed in outside shops by some of the roads that operate into Louisville.

Tapping the water supply of a coal mining company after the city reservoir was exhausted **saved the coal mining town of Clay** in the western field from destruction on April 5. Six buildings were destroyed and others damaged, the loss being about $100,000.

The Burclut Coal Co., of Middlesboro, capital $30,000, has been chartered by John W. Burnett, W. L. Burnett and George A. Clutts.

R. M. Watt, district manager for the Kentucky Utilities Co., at Pineville, recently obtained an option on well-located property as a site for a new $1,500,000 power plant.

The Reams Hardware Co., of Middlesboro, has taken over the mine supply business of Rogan Brothers Co., a branch of the Kentucky Mine Supply Co.

MASSACHUSETTS

Allan M. Macleod has been appointed New England representative of Dickson & Eddy, of New York City, effective May 1. He will have offices at 60 Congress Street, Boston, and will look after the interest of the company in that territory, including the development of its bituminous-coal business. Mr. Macleod is well known in the coal trade, having been associated with it since Dec. 1, 1904. In January, 1915, he became connected with the Northern Coal Co., remaining with that concern until Nov. 1,

ALLAN M. MACLEOD

1917, when he joined the Fuel Administration at Washington, becoming manager of the Zone Coal Permit Bureau when it was formed. In May, 1918, he became director of anthracite distribution under James J. Storrow, New England Fuel Administrator in Boston. During the 1919 coal strike he served as a member of the New England Sub-Committee of the Eastern Regional Coal Committee. In February of 1920 Mr. Macleod became associated with C. H. Sprague & Son Co., and as a representative of that concern made a tour of the United Kingdom, Holland, Belgium, Switzerland, Italy and France, remaining abroad until October of that year. On Sept. 15, 1921, Mr. Macleod was appointed executive secretary of the Massachusetts Emergency Fuel Committee.

The F. W. Pray Coal Co., Boston, was recently incorporated to engage in the coal business. The capital stock is $50,000 and the incorporators are Henry N. Berry, president; Ralph Crocker, Swampscott, Mass., treasurer.

The Central Coal Co., Lowell, is a recent incorporation, to engage in the coal business, with a capital stock of $100,000. The firm will conduct yards at Lowell. The president is John F. Cunha, and the treasurer, Edward F. Cunha, of Lincoln Park, Somerville, Mass.

MINNESOTA

A representative of the Combustion Engineering Co., of New York, addressed a joint meeting of the St. Paul and Minneapolis chapters of the American Society of Mechanical Engineers last week on **pulverized fuel and lignites.** He predicted that pulverized fuel would be the coming fuel for industry, and said that lignite might cut a considerable figure in fuel in this market if certain processes under experiment were perfected. **Three carloads of North Dakota lignite are to be tested out in two stations of the St. Paul Gas Light Co.** on underfeed stokers and traveling grates, to determine its effectiveness. The tests will be carefully watched by many who hope that lignite will prove to be an available fuel for the Twin Cities. The gas-light company has a new plant under construction which will go into service next season that will use pulverized fuel. It can use lignite or peat, if tests shall prove either of these to be satisfactory as a commercial proposition. Both will be tried in the new plant, when it is completed and in operation.

MISSOURI

Coal mines in Randolph, Lafayette, Henry, Johnson and Morgan counties, where some of the largest pits of the state are located, **will be benefited by the decision of the Missouri Public Service Commission, which has ordered a reduction of 17c. a ton in intrastate rates on coal.** The present rate of 97c. a ton is reduced to 80c. The decision was returned in the appeal of Edward Aull Coal Co., of Lafayette County, which charged that the present rates were excessive and discriminatory in favor of interstate traffic. The action for reduction was brought against the Atchison, Topeka & Santa Fe, The Frisco, Burlington, Chicago & Alton and Missouri Pacific Railroads.

MONTANA

The Northern Pacific RR. announces that it will build a new line from the Rosebud district to Forsyth, Mont., a distance of 34 miles, at a cost of $2,000,000. It will make semi-bituminous coal deposits available for open-pit mining.

NEW YORK

Former Congressman Charles B. Smith, as one of the receivers of the L. R. Steel Co., on returning to Buffalo from Montgomery County, Virginia, where he went to inspect the mines of the **Merrimac Anthracite Coal Co.,** which is a Steel Company promotion, expressed himself as favorably impressed with conditions there and thinks the company may prove to be solvent and capable of achieving final success.

Foote Bros. Gear & Machine Co., Chicago, **have moved** their New York office from 145 Greenwich St. to **larger quarters at 100 Greenwich St.** J. R. Shays, who has represented the company for many years, remains in charge of the New York office.

Senator Downing, of New York city, has introduced in the New York State Legislature **a bill** (Senate Print No. 2,134) **appropriating $10,500 for plans and specifications for constructing tipples** for coal at Ithaca and Watkins with a view to facilitating transportation and delivery of coal within the state and utilizing the barge canal for that purpose.

OHIO

The Kearns Coal Co., Cincinnati, has been incorporated with a capital of $200,000 for the purpose of mining and selling coal and coke both at wholesale and retail. Incorporators are G. M. Kearns, U. B. Buskirk, Howard N. Ragland, R. H. McCormick and Carl T. Foley.

The Joan Collieries Co., Marietta, has been chartered with a capital of 500 shares, no par value, designated to mine coal. Incorporators are E. H. Wigginton, H. G. Healop, R. M. Noll, Benjamin E. Jones and John Jones.

The Euga Coal Co., New Lexington, has been chartered with a capital of $5,000 to mine coal in the Hocking Valley. Incorporators are: J. A. Curtis, R. F. Roberts, M. Herstam, and E. Holwick.

The Landson Coal Co., of Hopedale, has contracted with the Roberts & Schaefer Co., for the complete erection of a new tipple at its stripping operation at Hopedale.

The Cincinnati Chamber of Commerce **will conduct a trade excursion** to points on the Norfolk & Western in West Virginia, down the Big Sandy and into the Hazard and Harlan coal fields as a means of strengthening the bonds between the city's merchants and distributors and the coal fields to the south and east.

C. D. Boyd, traffic manager for the Hazard Coal Operators Association and the Southern Appalachian Operators Association addressed the traffic committees of both associations at a meeting held at the Hotel Gibson, Cincinnati, on April 17. Many matters were gone over relating to tariffs, traffic and rates, but the matter that received the most attention was the controversy on rates between the Illinois shippers and the dock operators at the head of the lakes over Minnesota tariffs. Both associations decided to keep out of the discussion on the ground that this was "not their fight."

PENNSYLVANIA

The Diamond No. 3 Mine, located at Grove City, on the Bessemer & Lake Erie R.R., has been purchased by the Bixler Coal & Coke Co., of Pittsburgh, which company intends to install modern equipment and operate the mine to its full capacity.

The Central Cambria Coal Mining Institute was organized April 12 in the public school building at Portage. The purpose and aim of the organization was discussed and the following officers elected: President, Dennis J. Keenan, of the Portage Wilmore Coal Co.; First Vice-President, Thorne Murphy, of the Sonman Shaft Coal Co.; Second Vice-President, James R. Cunningham, of the Forge Coal Mining Co.; Third Vice-President, Frank J. Burke, of the Sonman Shaft Coal Co.; Secretary, Jerome C. White; Treasurer, Leo M. Cronaur. The election of a Board of Directors was left until the next meeting. A committee on bylaws and constitution was elected and ordered to report at the next meeting. The institute has for its purpose to foster a better fellowship among those interested in the mining industry, to study and discuss the problems of the industry with a view toward their practical solution; to assist in accident prevention, to help collectively and individually to make a safe industry for those whose lives are given to this work, and to assist in educational work both for its members and mining men in general.

Schuylkill County Commissioners on April 13, forced an immediate issue with coal companies who have refused to pay a 1,000-per cent increase in coal-land taxation, by ordering the tax collectors to levy immediately upon and sell breakers, horses, coal, mules and coal cars, and even railroad cars where the tax increase has not been paid.

The Colonial Coal & Coke Co., Pittsburgh, has been appointed sole **selling representative of the Maple Furnace Coal Mine,** owned by the Argentine Coal Mining Co. The combined output of the North East Coal Mining Co., the Standard Coal Mining Co. and the Argentine Coal Mining Co., makes the Colonial company the largest shipper in Group 1 on the Bessemer. The company's coal is produced under the personal supervision of Harris T. Booker, formerly general manager for the Berwind White Coal Mining Co.

The Board of Education of Philadelphia on April 10 **approved the awarding of contracts for furnishing coal** for the school buildings for the ensuing year, at the following prices: Egg, stove and chestnut, $10.67 per ton; pea coal, $8.14, and buckwheat No. 1, $5.44. Hauling of anthracite is to cost from 90c. to $1.47 per ton. For furnishing bituminous coal the prices range from $8.36 to $8.40 per ton.

A well-defined break has appeared in the ranks of the United Mine Workers in the Ninth district, of which C. J. Golden, of Shamokin, is president, according to the *Wilkes-Barre Leader.* Representative of forty-five locals met at Ashland recently and went on record as opposing the institution of the colliery local plan, which is being put in force by the district officers. A committee representing these insurgent locals, issued a statement April 14 in which they declared their intention to resist every effort to change the present system. The insurgents admit that the colliery local plan passed the Shamokin convention by an aye and nay vote, but contend that when the plan was submitted to a referendum vote, it was defeated by at least 800 votes. Action of the District officers in throwing out votes sent in by locals opposed to the plan because returns were not made within the time specified, lost that number of votes to the antis, they claim.

The House on April 16 passed the O'Boyle bill requiring owners and operators of coal mines and operations to furnish and sell coal at current or market prices to hospitals, poor houses, schools, churches and municipal buildings. Representative Edmonds, Philadelphia, asked the sponsor of the bill the purpose of the measure and was told that during the coal shortage of the past winter the Delaware & Hudson Coal Co. would not sell coal at any price to a hospital and a school building near its operations in Lackawanna County. There was no opposition voiced on the floor of the House to the measure.

A bill authorizing the Chief of the Department of Mines to appoint a Mine Inspectors' Examining Board was introduced in the Senate April 17 by Senator George Woodward, Philadelphia. The board is to be composed of two mining engineers who have had experience in the anthracite district and two who have had similar experience in the bituminous mines, two who shall have passed examinations qualifying them as inspectors or mine foremen in the anthracite mines and two who have been qualified for similar positions in the bituminous mines. The minimum age limit of members of the board is thirty years. Mine inspectors are now named by the Governor.

Senator Buckman, Bucks County, offered a bill in the Senate April 16, amending an act of 1881 to provide that all domestic corporations and all foreign corporations which have at any time been registered in the Commonwealth, organized for mining, manufacturing or trading purposes, whether created by general or special laws, whose charters have expired or may hereafter expire or may be dissolved, which at the time of the expiration of the charter or dissolution are owners or holders of record of property in Pennsylvania, **may sell the property and make title as effectually as if their charters had not expired.**

The House on April 12 passed finally the first of the series of bills affecting the coal industry of Pennsylvania. It was the Post measure, which is intended to **relieve life tenants of land from the payment of taxes on the underlying veins of coal which they have no right to operate.** The bill provides that such coal shall be assessed to and the taxes on it paid by the owner of the coal. The bill was sent to the Senate this week.

Joseph J. Walsh, Chief of the Bureau of Mines and Mining, announces that but **eight examinations of candidates for certificates as mine foremen and assistant mine foremen will be held** in the anthracite region this spring because of lack of funds. In other years twenty-two boards sat in various parts of the region. The examinations will be held on April 30 and May 1 at the following places, and with the following acting as chairman of each board, consisting of the inspector, a mining engineer and two experienced miners: Carbondale—P. J. Moore, districts 1 and 2. Scranton—David T. Williams, districts 3, 4, 5, 6, 7. Wilkes-Barre—David T. Davis, districts 8, 9, 10, 11, 12, 13, 14. Hazleton—D. J. Roderick, districts 15 and 16. Coaldale—E. G. Evans, 17 and 18 districts. Pottsville—M. J. Brennan, districts 19, 20 and 21. Shamokin—P. J. Friel, 22, 23 and 24th districts. Lykens—Charles J. Price, 25th district. Instead of taking the examinations in their respective mine inspection districts candidates will have to appear before the boards as per the above schedule.

Joseph J. Walsh, of Wilkes-Barre, who has been serving as chief of the Bureau of Mines and Mining since Governor Pinchot took office, was **named by the Governor for a full term of four years** commencing April 17. The appointment was immediately confirmed by the Senate, the action being unanimous.

Fire, the origin of which has not been determined, on April 13, **gutted the entire upper half of the washery of the Lackawanna Valley Fuel Co.,** in the Pine Brook section of Scranton. Destruction of the entire wooden frame structure was prevented only by effective work on the part of the firemen. The loss is estimated at between $12,000 and $15,000.

Berne H. Evans, of Harrisburg, was the only speaker at the Senate judiciary general subcommittee hearing on the Joyce compensation bill at Harrisburg, on April 17. He represented the Pittsburgh Coal Producers' Association, the Central Pennsylvania Coal Producers' Association, most of the large producers of anthracite and many other large employers of labor. **These interests, he said, are unqualifiedly opposed to the bill, which will raise the maximum compensation to $20 a week** and base the compensation on 66⅔ per cent of the weekly wage. The present law has resulted satisfactorily, he said, for it has been humane to both labor and industry. Roger Dever, attorney for the anthracite mine workers; Thomas J. Kennedy, District 7, United Mine Workers, and J. B. Crumrine, District 5, spoke for the measure.

Contract miners at the Jeddo No. 4 and 7 collieries of the Jeddo Highland Coal Co. struck April 14 in a renewed **demand that they receive their wages on pay days at 2 p.m.** when they come from the workings, instead of being obliged to wait until 3:30, when the pay windows open. Both places were tied up and 600 men were idle. The men, it was stated by their leaders, would remain idle every pay day unless the hour for the wage distribution was changed.

RHODE ISLAND

Colonel George H. Webb, Fuel Administrator for Rhode Island, in his report to Governor Flynn **says that in no case has any dealer been found to have charged a customer more than $16 per ton for coal which did not warrant the charge,** and cases were found where coal selling at $19 and $20 per ton showed no profit to the dealer. "If the federal government," said Colonel Webb, "will correct the basic cause of the fuel conditions which periodically threaten the public welfare and health, protective state law can easily correct such unfair practices as may arise from time to time within the state." The report states that retail prices for coal were based on prices paid by the dealers, which ranged from $8 to $14.95 per gross ton f.o.b. at the mines. Sixty-five per cent of the coal was company coal, supposed to be sold from $8 to $8.50, and 35 per cent was independent coal, costing as high as $14.95 and inferior in quality to the $8 coal.

UTAH

The Carbon County R.R., being built for the Columbia Steel Corporation, to open coal deposits in Horse Canyon, **is expected to be ready for service the first week in May.** Work at the mine is under way and it is probable that coal will be produced on a commercial basis by August 1. The coke oven and blast furnaces should be ready early next year. Pig iron ought to be produced by Apr. 1, 1924.

Thomas E. M'Kay has been made president of the Utah State Public Utilities Commission. He was president of the Senate for two terms. He is a resident of Huntsville and a prominent church man in that section.

WEST VIRGINIA

Carrying a provision that it should be considered only as an emergency measure and should be in effect only for the next two years, House Bill 149—**the Zimmerman bill—imposing a privilege tax on the production and sale of coal** and other mineral products as well as on manufacture and sale of tangible property, sales at retail, a tax on the gross profits of wholesalers, a tax on the gross income of banks, railroads and other public utilities and on engaging in business, was reported to the House of Delegates on Tuesday, April 17, by the Finance Committee of the House. The measure as reported provides for an increase in the rate on coal, oil and gas from two-fifths of one per cent under existing law to 1 per cent.

During consideration of the **Helmick bill creating the West Virginia School of Mines which passed the State Senate** April 17, by a vote of twenty-four to two, the only discussion of the bill arose over the question of location, Senator Kidd, of Gilmer, stating that he was in sympathy with the measure but he asked if it should not be located at the University. He was assured by Senator Helmick, patron of the measure, that the bill created a commission of five to decide upon the proper location for the school especially with a view to avoiding duplication.

A bill designed to abolish the state police in West Virginia was removed from further consideration for two years by the Legislature when the House voted definitely April 18, **to postpone action on the measure.** Proponents of the measure declared the act creating the state police set up "a military regime," while its opponents contended the troopers were not a military force.

Clarksburg capitalists have launched the Bailey-Spraker Coal Co. for the purpose of mining coal in the Harrison County field, this company being capitalized at $25,000. The general office of the company will be at Clarksburg. Largely interested in the new concern are K. D. Bailey, C. F. Bailey, E. L. Spraker, Anna May Spraker and Harry W. Sheets, all of Clarksburg.

WISCONSIN

The Valley Coal and Dock Co. has purchased 500 ft. of dock frontage on the Menominee River at Milwaukee, and will proceed to equip it with facilities for unloading vessels and otherwise handling coal. Until the necessary machinery is installed coal will be discharged on the dock by self-unloading steamers. The company contemplates adding to its frontage in the near future.

The State Fuel Administration of Wisconsin is **investigating the sales methods of a Chicago coal company** which advertises that it will save "special agents" in Wisconsin from $1.50 to $2 per ton on coal and pay 75c. per ton commission on all sales. The company advertises that working agents without investment or experience should be able to earn from $100 to $200 per week as its representative. The Fuel Administration demands to know the name of the mine and operating company, and the shipping point.

A bill to increase the occupational tax on coal handled over docks in Wisconsin, now before the Legislature of that state, would increase from 1½c. to 2½c. the tax per ton on bituminous coal, and from 2c. to 3c. per ton the tax on anthracite. The measure is discriminatory in that it does not apply to coal received direct by rail.

WASHINGTON, D. C.

Bids are solicited for the transportation of four cargoes of Navy coal from Hampton Roads, Va., to the destinations specified below, in vessels of American registry. The destinations, guaranteed daily rate of discharge, cargoes required and approximate loading dates at Hampton Roads are as follows: 7,500 tons to Puget Sound Navy Yard; 5,000 tons to Portsmouth (N. H.) Navy Yard; 7,500 tons to San Diego (Cal.) Naval Fuel Depot, and 5,000 tons to Boston Navy Yard. Proposals, which should be submitted to the Bureau of Supplies and Accounts, Navy Department, Washington, D. C., will be opened at noon May 3.

Chambers of Commerce have indorsed trade associations for each important branch of industry in a referendum concluded by the national organization. Eight propositions were voted on, all of which were carried by large majorities, the negative votes being in five cases less than 100, and in 3 cases less than 300. It was voted that trade associations should be free from special forms of government control; that statistics of capacity, production, stocks, and sales should be collected, as well as statistics of acual prices in closed transactions but that any interpretation of statistics or other comment which would induce or facilitate concerted action by members should be omitted. It was also voted that statistics should be made available to the public and to government agencies.

"One of the first things Congress will try to regulate," said Representative Bacharach of New Jersey, "when we return next year, will be the question of coal. It is a well known fact that we had a coal commission that accomplished nothing worth while. I was strongly opposed to the government sending coal to Canada and other ports, while we ourselves were suffering from the shortage of fuel. There is hope, and I sincerely wish that it comes true, that **there will be a commission appointed at the next Congress** that will relieve the situation and do something for the benefit of the suffering public and not worry about other countries. **We should have a sales tax** and I am the sponsor of the movement and one of its heartiest supporters. At the present time, no matter what way you try to get around it, any tax you put on the rich man the poor man pays. Since this tax has been advocated eighteen states throughout the country have passed like taxes, and each has been successful. The tax prevents confusion and worry about the income tax."

J. F. Callbreath, secretary of the American Mining Congress, **will leave about May 1 for a tour of the West.** It is probable that Mr. Callbreath will address the National Foreign Trade Council in New Orleans May 2 or 3 on the silver situation, and the inquiry into that subject by a Senate committee. He will speak at the commencement exercises of the Colorado School of Mines May 18, and will make one or two other addresses before leaving that state; will attend the convention of the Northwestern Mining Association at Spokane, May 22-26, and will attend a meeting of the Board of Governors of the Western Division of the American Mining Congress at San Francisco, June 11-13.

CANADA

Production of coal in the province of Alberta is showing an increase. Last January 245,300 tons more were mined than in the corresponding month last year. The total output for January, 1923, was 845,806 tons, of which 347,673 tons is classified as domestic, 74,457 tons sub-bituminous and 423,676 tons bituminous. In January, 1922, there were produced 312,871 tons of domestic, 30,989 sub-bituminous, 246,788 bituminous and 9,858 anthracite. In January, 1922, some 829 tons of domestic were shipped to Ontario while in January of this year the export to that eastern province totalled 5,239 tons. Shipments to adjacent provinces also are growing so that it is clear that the campaign being carried on by the Alberta Collieries, assisted by the authorities of the provincial and federal governments, already is bringing results.

Minister of Mines Sloan has issued a statement **favoring the use of the new "self-rescue" gas mask** for miners if that little device, recently put on the market in the United States, fulfills expectations. It is a small tin can with a mouthpiece and a nose clip. A miner easily can carry it in his pocket. It is calculated to give 70 minutes protection against a considerable percentage of carbon dioxide but will not, of course, replace oxygen equipment, as it cannot be used in an atmosphere completely robbed of oxygen, as by a serious explosion.

Traffic News

Railroads of the country on April 1, 1923, had 50,107 serviceable locomotives, the largest number the railroads have ever had, according to the American Railway Association. Locomotives in need of repair on that date numbered 14,452, or 22.4 per cent of the total number on line. This was a decrease of 1,179, compared with the total on March 15, at which time there were 15,631, or 24.2 per cent. The total number in need of repair on April 1 was practically equivalent to July 1, 1922.

A total of 8,242 new freight cars of various classes and **208 new locomotives** were installed in service by the railroads during the semi-monthly period from March 15 to April 1 according to reports just filed by the carriers with the American Railway Association. This brought the total number of **new freight cars installed from Jan. 1 to April 1, 1923, to 39,172,** while **935 locomotives** were placed in service during the same period. **New freight cars on order on April 1 totaled 107,453,** or an increase of 1,117 over the total number on order on March 15. There were also 1,974 locomotives on order on April 1 compared with 2,113 on March 15. Of the total number of freight cars put in service during the first three months this year, 14,895 were coal cars.

The membership of the **Board of Directors of the Chesapeake & Ohio Ry. was increased from nine to eleven** at a meeting of the stockholders at Richmond, Va., April 17. A. Colston, Cleveland, and Walter L. Ross, Toledo, were elected to the new places. The other members of the board elected at the meeting are O. P. Van Sweringen, chairman; M. J. Van Sweringen, J. J. Bernett, C. L. Bradley, H. M. Hanna Jr., Otto Miller and J. R. Nutt, all of Cleveland; W. J. Harahan, Richmond, and W. J. Louderback, Chicago.

The Interstate Commerce Commission, on April 21, ordered **Service Order 22 vacated and set aside,** effective at midnight April 22, 1923.

It has been definitely announced that **the Virginian Ry. will be electrified from Mullens, W. Va., to Roanoke** and that contracts for the work will be awarded soon. The road will install motors of the largest capacity and will make every provision for the most modern system of electrification. It will take about a year and a half to complete the work, but by Jan. 1, 1925, officials of the road expect it to be able to handle about 12,000,000 tons of coal annually.

A refund of certain demurrage charges paid by the Republic Coal Co., of Minneapolis, was ordered.

The Interstate Commerce Commission holds that rates on **coal from Willard, Ky., to certain destinations in Kentucky, during February control, were unreasonable,** as was the rate on certain shipments to Cincinnati. The carriers were instructed to pay reparation to the Willard Coal Co. and to the Drayer Coal Co.

The Kanawha Central Ry. is a common carrier, according to a formal opinion rendered by the Interstate Commerce Commission. The line is the property of the Black Band Consolidated Coal Co. Its only connection is with the Chesapeake & Ohio at Brounland. In the same opinion the commission holds that **rates on coal from mines on the Kanawha Central to interstate destinations are unreasonable** to the extent that they exceed the group rates on like traffic from other mines in the Kanawha district which are served by the Chesapeake & Ohio. The commission expresses the opinion, however, that the **Kanawha Central should receive a greater proportion of through rates.** It is suggested that the two lines make an effort to agree on reasonable and proper divisions.

The Sturgeon Grain & Coal Co., of Muncie, Ind., has **attacked the rates on bituminous** coal from Springfield, Ill., to Muncie.

The Valley Camp Coal Co., of Cleveland, has filed a complaint **assailing the rates on coal** from mines in the Moundsville district of West Virginia to Lorraine, Ohio, for transshipment to Superior, Wis.

Consolidation of five Middle Western railroads under the direction of the Van Sweringen interests of Cleveland, was **officially consummated** April 12, when incorporation papers for the consolidated road, which will be known as the New York, Chicago & St. Louis, were filed with the Ohio Secretary of State at Columbus. Railroads which under the merger are brought together into one system are the New York, Chicago & St. Louis, Chicago & State Line, Lake Erie & Western, Fort Wayne, Cincinnati & Louisville and the Toledo, St. Louis & Western. Officers of the company include O. P. Van Sweringen, Cleveland, chairman of the board; J. J. Bernett, Cleveland, president; Walter L. Rees, Toledo, senior vice president; M. J. Van Sweringen, Cleveland, J. R. Nutt, Cleveland; C. L. Bradley, Cleveland, Otto Miller, Cleveland; John Sherwin, Willoughby; C. E. Denney, Cleveland, and W. A. Colston, Cleveland, vice presidents; George A. Ross, Toledo, secretary and L. B. Williams, Cleveland, treasurer.

Obituary

Joseph Meister, prominent coal operator of eastern Ohio and West Virginia, died on April 11, at his temporary residence 45 Zane St., Wheeling Island. He was in his fiftieth year and had resided in Bridgeport practically all of his life. He was president and owner of the Meister Coal Co. and officially connected with other mining operations in Ohio and West Virginia. He also was a director of the Bridgeport National Bank and a member of the Pittsburgh Vein Operators Association of Ohio. At the time of his death he was a member of the Bridgeport Council and had been a candidate for mayor. He was one of the benefactors of the Meister band, one of the best-known and most successful organizations in the Tri-state district. Mr. Meister was himself a talented musician.

R. C. M. Hastings, aged 56, president of the Crab Orchard Mining Co., which operates coal properties at Freeport, in Harrison County, Ohio, died suddenly last week at his home in Columbus, from heart trouble. He had been a resident of Columbus for about 12 years and was also in the telephone business. He leaves a widow and three daughters. Interment was at Athens, his former home.

John S. Hobson, 59 years of age, salesman for the Gulf Refining Co., Louisville, and for twenty years sales manager for the old Central Coal & Iron Co. mines, at Central City, Ky., recently died at his home in Louisville, where he has been living for the past nine years.

James S. Kuhn, 55, president of the Devoy & Kuhn Coal Co., wholesalers, died suddenly at his home in St. Louis of heart failure, April 12. For 31 years he had been connected with the Devoy & Kuhn company, which specialized in railroad fuels. Besides a widow he leaves two married daughters.

Edward Lippincott Bullock, mining engineer and former superintendent of the Dodson and Lehigh & Wilkes-Barre mining operations in Luzerne and Schuylkill Counties, died at his home at Hazelton April 8. He was 79 years old.

Association Activities

Cleveland Wholesales Distributors Association

The Cleveland Wholesale Distributors Association held its annual frolic on Wednesday evening, April 11, at Grove Hill, a popular summer resort just east of Cleveland on the shores of Lake Erie. About 150 of Cleveland's leading coal jobbers were present and addresses were made by the officers. Roy S. Bain, sales manager of the Central Coal Mining Co., is president of the association and Eugene Astel, of the Astel Coal Co., is vice president.

Baltimore Coal Exchange

The banquet of the Baltimore Coal Exchange held last week was addressed by William M. Maloy, chairman of the Public Service Commission and former chairman of the State Fuel Distribution Committee; A. S. Goldsborough, managing director of the Merchants & Manufacturers Associations; Walter R. Hough, Fire Commissioner and publisher, and Charles B. Crockett. J. Harry West was toastmaster. Hugh C. Hill is president of the exchange. Mr. Maloy predicted the coming of a form of regulation to the coal trade by governmental agency, but said that be believed that it would have a stabilizing effect which would be beneficial to the retail dealer rather than destructive to his interests.

Coming Meetings

The American Wholesale Coal Association will hold its annual convention June 12 and 13 at the Gibson Hotel, Cincinnati, Ohio. Secretary, G. H. Merryweather, Union Fuel Bldg., Chicago, Ill.

Illinois and Wisconsin Retail Coal Dealers' Association will hold its annual meeting June 12-14 at Delavan, Wisconsin. Secretary, I. L. Runyan, Great Northern Building, Chicago, Ill.

Southwestern Interstate Coal Operators' Association will hold its annual meeting June 12 at Kansas City, Mo. General Commissioner, W. L. A. Johnson, Kansas City, Mo.

Pennsylvania Retail Coal Merchants' Association will hold its annual meeting May 23 and 24 at Wilmington, Del. Secretary, W. M. Bertolet, Reading, Pa.

American Association of Mechanical Engineers will hold its spring meeting at Montreal, Quebec, Canada, May 28-31. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

National Association of Purchasing Agents will hold its eighth annual convention and Informashow at Cleveland, Ohio, May 15-18. Convention headquarters, room 219, Hotel Winton, Cleveland.

The National Association of Manufacturers will hold its 27th annual convention at the Waldorf-Astoria, New York City, May 14-16.

New England Coal Dealers' Association will hold its annual meeting at Providence, R. I., June 13-15. Secretary, C. R. Elder, Boston, Mass.

National Retail Coal Merchants' Association will hold its sixth annual convention June 25, 26 and 27 at Scranton, Pa., with headquarters at the Hotel Casey.

National Safety Council will hold its twelfth annual safety convention at the Buffalo Statler Hotel, Buffalo, N. Y., Oct. 1-5. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

International First-Aid and Mine-Rescue meet will be held Aug. 27-29, at Salt Lake City, Utah.

American Institute of Electrical Engineers will hold its annual convention June 25-29, at Swampscott, Mass. Secretary F. L. Hutchinson, 29 West 39th St., New York City.

International Railway Fuel Association will hold its spring convention at the Hotel Winton, Cleveland, Ohio, May 21-24. Secretary-treasurer, J. G. Crawford, Chicago.

The American Mining Congress will hold its twenty-sixth annual convention in conjunction with the **National Exposition of Mines and Mining Equipment,** Sept. 24-29, at the Milwaukee Auditorium, Milwaukee, Wis. Secretary, J. F. Callbreath, Washington, D. C.

American Society for Testing Materials will hold its annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, N. J., beginning June 25 and continuing throughout the week. Secretary, E. Marburg, Philadelphia, Pa.

The Colorado & New Mexico Coal Operators' Association will hold its annual meeting June 20 at Denver, Col. Secretary, F. O. Sandstrom, Denver, Col.

The Electric Power Club's annual meeting will be held at the Homestead, Hot Springs, Va., June 11-14. Executive secretary, S. N. Clarkson, Cleveland, Ohio.

National Foreign Trade Council will hold its annual conference May 2-4 at New Orleans, La. Secretary, O. K. Davis, 1 Hanover Square, New York City.

The eleventh annual meeting of the Chamber of Commerce of the United States will be held in New York City May 7-10.

National Coal Association will hold its sixth annual convention June 19-22 at Atlantic City, N. J. Assistant secretary, C. C. Crowe, Washington, D. C.

Michigan-Ohio-Indiana Coal Association will hold its annual convention at the Hotel Sinton, Cincinnati, Ohio, May 22-24. Secretary, B. F. Nigh, Brunson Bldg., Columbus, Ohio.

West Virginia Coal Mining Institute has tentatively set June 5 and 6 for its annual meeting, to be held at Clarksburg, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 23 NEW YORK, MAY 3, 1923 Number 18

The Massachusetts Pure Coal Law

MASSACHUSETTS is again to the fore. The authorities who procrastinate over an archaic state prison (built in 1801) are prompt and conclusive in dabbling with coal. A governor who deals pettishly with the officer who drove out two corrupt district attorneys now has the credit for forcing through a statute that deserves a place with legislative curiosities. After empowering "the Department of Public Health, local boards of health, the director of standards and local sealers of weights and measures, by themselves or by their authorized agents," to inspect and sample coal wherever "stored or kept for sale," the Pure Coal Law (approved March 23, 1923) includes the following extraordinary provision:

> If, in the opinion of said department or board, upon inspection, analysis or other satisfactory test, said coal is unfit for ordinary use, said department, or said board, with the approval of said department, may condemn, seize and cause the same to be destroyed forthwith or disposed of otherwise than for ordinary use.

The words "anthracite" or "bituminous" occur nowhere in the act; it is "coal" and "opinion," plus confiscation! Like poison is 10 per cent pea in chestnut, and the "health" experts are to determine whether long fracture or rectilinear faces are "fit for ordinary use." And what about drafts and flues? Must the dealer guarantee these also, or suffer seizure and disposal "otherwise than for ordinary use?" Shall he be allowed the comfort of seeing his fellow citizens supply their casual needs from the public dump while he pays the producer? We find ourselves wondering whether in Moscow political genius can match this. "Local sealers of weights and measures" have been modest functionaries, but now is their light hid under a bushel.

But, to continue with this enlightened law:

> Whoever, by himself, or by his servant, agent or employee, sells, exposes or offers for sale, or has in his custody or possession with intent to sell, coal unfit for ordinary use shall be punished by a fine of not more than one thousand dollars or by imprisonment for not more than one year, or both.

There are the teeth. "Quick! To the dump, or we are lost!"

No standards or tests are prescribed. "Opinion" only is to control. The provisions bear dangerous resemblance to decrees of absolutists; they have nothing in common with "due process" or "liberty under law." Like intrastate attempts to regulate trunk lines, such legislation is sophomoric, is based neither on sound principle nor on proper study. But there is still a Constitution, and not to any appreciable degree will neighborhood Rob Roys be permitted to "condemn" and dispossess.

There will be instances of pique and meddlesome interference, doubtless, but the vacation season is coming on. The local sealers and local custodians of the public health will not as a rule persist in "seizure" and "disposal." The act bestows no emoluments save upon hungry laboratories. The volume of really "fireproof" output is egregiously small, and will be precluded from the channels of trade in any case. A few—a very few—operators will blacklist Massachusetts for a time, but anthracite will come forward probably by leaps and bounds during the summer; Massachusetts will have retired her famous Commission on the Necessaries of Life; and in 1924 the electorate will be called upon to give suffrage to eminent statesmen who by once taking thought improved prodigiously the quality of coal for the people.

"It is a great privilege to preside over the destinies of Massachusetts." The rest of the nation must be made aware that pure coal and pure coal only will be received within her borders. Petty annoyances to retail dealers, yes; but dealers are inimical to the public good, anyway, and who cares? And around the whole proceeding, much as in 1903, will gradually fold the mantle of forgetfulness, if only there is no publicist lurking about with an axe to grind!

Publicity, Accusation or Information?

THERE are several reasons why information and statements from the mine workers, the coal operators, the railroads and groups of consumers, as the public utilities, prepared and submitted to the U. S. Coal Commission from time to time should be given to the public. The commission represents the public, and when all the evidence is in it has the responsibility of rendering decisions based on the facts. It is in a measure both judge and jury, with the public in the end passing judgment both on the facts as presented and on the wisdom of the commission. Public opinion therefore should be in the making as the matter of investigation proceeds. Publicity for the high points in the arguments of either side may well be depended upon to prepare the public mind in advance for the final conclusions.

The mine workers, the bituminous-coal operators and the anthracite operators have each been issuing statements to the press as well as to the commission. It is interesting to note the general tenor of these documents. In point of frequency of issue and of prolixity those from Ellis Searles, of the United Mine Workers, carry off first honors. Being a publicist and an able one, Mr. Searles has had an eye on the headline value of his stuff; he has had less concern over fundamental facts than news value. He opened up six months ago with the field to himself, in an attempt to be constructive by urging complete unionization of the coal fields as a cure for all the ills of the industry. This hope and ambition of the union has not subsequently been lost sight of.

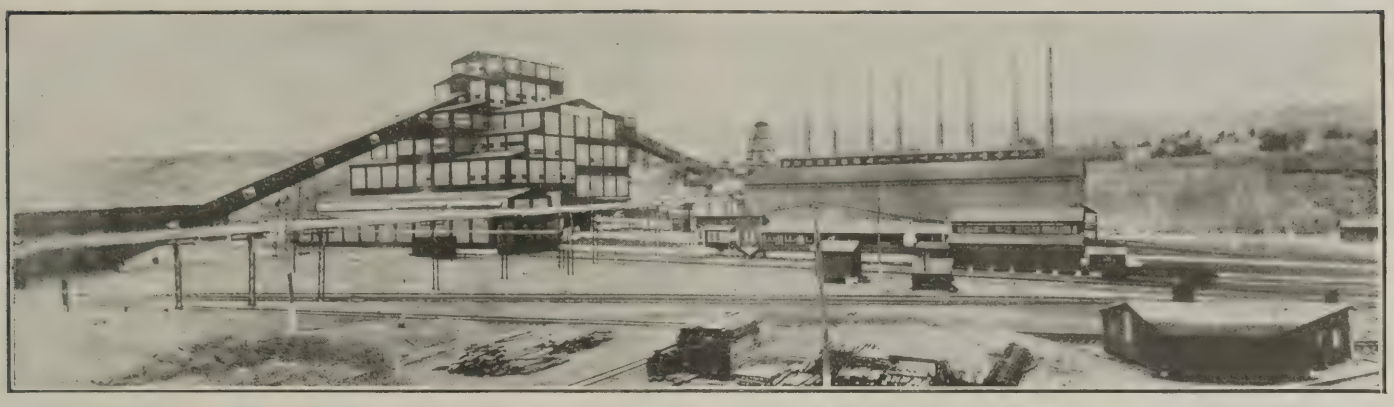
The virtues of the United Mine Workers have been expounded, the hardships and hazards, the patriotism and loyalty of the miners set forth. The "Reds" have been denounced and trounced, nationalization of the industry decried. Local strikes have been ascribed to overbearing mine foremen, major strikes described as lockouts by the employers. On the other hand the spokesman for the miners does not hesitate to lay high prices for coal to the conscienceless greed of operators, middlemen and speculators; to charge taking of undue profits. In short, the fault for all that is wrong, both as viewed by the consumer and the digger of coal, is laid at the door of the producer and distributor of coal. Serious enough at the beginning, the "press releases" of the United Mine Workers have descended to mere childish talk. Serious or facetious, the whole effect is that of *publicity*, not of helpful suggestions for the Coal Commission or the public on the very important matter of circumventing strikes.

The anthracite operators have had little to say to the commission. What they have put before it and the public is their record, first with respect to the strike of 1922 and second with respect to their participation in distribution of a short supply of hard coal last winter. In both their performance is clearly shown to have been overwhelmingly exemplary. They do not launch an attack at the miners' union; on the contrary they show the steps taken by the operators to prevent and later to terminate the strike. Mere recital of the things they were ready to do in that direction that the miners refused to consider is sufficient condemnation of the union. They offered the miners last year every possible form of conciliation and arbitration. It seems that they may be excused if the Coal Commission or the miners be now asked to suggest some other avenue of approach to strike prevention. There remain some very important topics for the anthracite industry to discuss, however.

The bituminous-coal operators, on the other hand, have not been telling people how good they are but how very awful the other fellow—the United Mine Workers—is. The soft-coal people have not attempted to prove that they are without reproach, but they have robbed the union of any claim to virtue. The attack has been forceful, direct, condemnatory. The running story of murder and arson by which the United Mine Workers has sought to maintain and extend its monopoly of coal-mine labor is conclusive in its grewsome details. Where does it lead? What does Colonel Stimson think is the answer? Is the union to be torn out root and branch? For its arrogant attitude and high-handed tactics since the war the United Mine Workers is deserving of the two-fisted pummeling the soft-coal operators are handing it but the fact should not be lost sight of that the stronger the case of union power is built, the greater is the evidence of weakness on the part of the operators.

Gloomy indeed will be the picture if all that is painted on the canvas is a hairy giant defying alike the President of the United States and the coal operators while battering at the portals of the non-union fields. The non-union operators may well be expected to resist to their utmost that entrance, but what about the union operators, of whom the majority most certainly would not abolish unionism if they could?

On the whole, as pointed out by Commissioner Marshall recently, this sort of publicity and report to the Coal Commission will get no one anywhere.



Dock Operators on Defensive

HEARINGS begin this week at the Twin Cities before the Interstate Commerce Commission on the complaint of the Northwest Coal Dock Operators' Association in the matter of the differential between the rail-lake-rail cost of hauling coal from the Appalachian fields and the all-rail rate from the Illinois and Indiana fields. It is the contention of the dock operators, as set forth in their brief to the Coal Commission in February of this year, that the "penalties, restrictions and discriminations against the use of the Great Lakes as a coal route have accumulated since 1916 in such number and in such manner that it can no longer claim the economic relation it has borne to our national transportation system." The specific complaint that is now under consideration concerns only the relation of rates from the upper docks to inland points as compared with the all-rail rates to those same points from Illinois and Indiana, but it is a part of the general campaign to reinstate the pre-war advantage held by Eastern coal in the Northwest.

These same dock operators have just been cited to appear before the Federal Trade Commission and answer to the allegation that they have been maintaining unlawful trade practices in the distribution of their coal. It is alleged, for instance, that the distributors of dock coal have "discriminated in price between different purchasers" and that the effect of this discrimination has been substantially to lessen competition and that it has tended to create a monopoly in the sale of coal. Thus while they are seeking to have restored a differential in freight rates comparable to that enjoyed when the dock coal business was built up, they are called upon to defend the trade practices that have been a factor in building up that business.

Specifically what has happened in the matter of rates is that the Interstate Commerce Commission in the course of advances from 1917 to date, and the Railroad Administration, during the war, have added $1.74 to the pre-war charge on rail transportation for the two short hauls for Eastern coal to destinations in the Northwest and have added $1.17 to the one long haul on coal from the mines in southern Illinois to the same destinations. That is to say, the price advantage for a buyer is now 57c. in favor of Illinois coal as compared to what it was six years ago. This has come to pass because the Interstate Commerce Commission has considered the movement from the mines in the East to a destination in North Dakota, for instance, as two unrelated hauls and has applied each advance in rates to each portion of the haul.

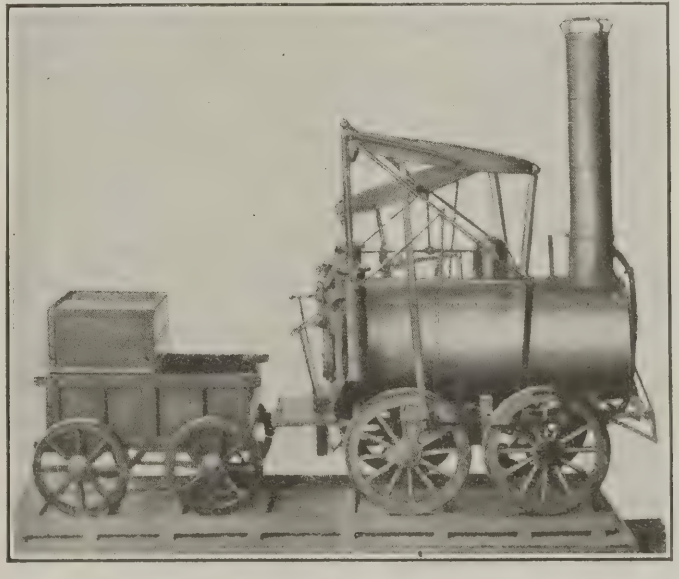
Shippers of Illinois and Indiana coal would like a larger share in the summer business offered by the Northwestern market. Lack of summer trade has always put a deep dent in the production curve of the mines in those fields and the Lake trade has for years put a hump in the production curve of the lake shippers during the summer months. Railroads serving Illinois and Indiana, likewise eager for coal traffic during the summer, have put in effect low rates favoring this long-haul business, as to the Twin Cities. Doubtless it will be contended that if the Western roads have equipment that would otherwise be idle during the summer months there should be no objection to permitting the long haul at the low rate and thus to enable Western shippers to even out their operating curve.

Delaware & Hudson, Chartered a Hundred Years Ago, Opens Mines and Builds Road and Canal to Hudson

Philadelphia Clothiers Prospect Around Carbondale—Try to Enter Philadelphia Market and Lose Heavily—Consequently Build Engine and Gravity Planes to Honesdale and Canal to Rondout—English Engines Purchased and Scrapped

TO THE efforts of the Wurts brothers, members of a prosperous firm of clothing manufacturers in Philadelphia, the Delaware & Hudson Co. owes its existence. They desired to market in New York City the anthracite, or "stone coal," as it was then termed, which they had prospected in the upper valley of the Lackawanna River. The company was incorporated by an act of the Legislature of the State of New York on April 23, 1823, just about one hundred years ago.

The preamble to the act of incorporation explains the general purpose behind the formation of the company. It reads:

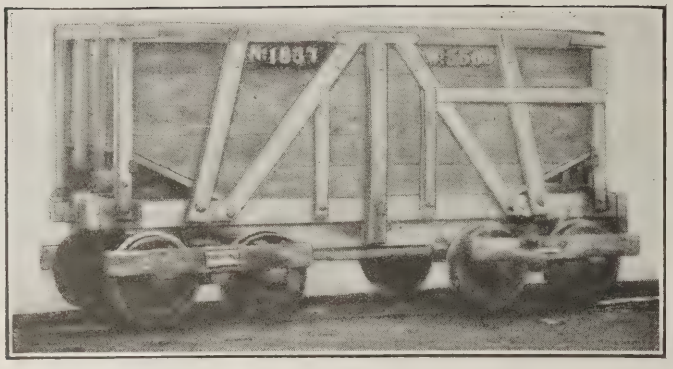


"Whereas, it is desirable that a channel should be opened, through which the City of New York and other parts of this state may receive a supply of stone coal, which is found in the interior of the State of Pennsylvania. And whereas, there is a large body of this valuable article, belonging to Maurice Wurts, in the said State of Pennsylvania, situated near the head waters of the river Lackawaxen, which empties into the river Delaware, opposite the county of Sullivan; and the Legislature of that state has recently passed an act authorizing the above-named individual to improve the navigation of the said river; and whereas, it is represented that a water communication can be formed between the rivers Delaware and Hudson, through the counties of Orange, Sullivan and Ulster, or some one or more of them, so that a supply of this coal may be had from the source aforesaid; and a number of citizens of the state have petitioned the Legislature to incorporate a company for the purpose of making such a communication between the said rivers: Therefore . . . "

This preamble shows both the original purpose behind the forming of the company and the purpose which shaped its course for many years, namely, to mine and distribute anthracite from northeastern Pennsylvania to the State of New York; and, as a natural development, to large portions of New England and Canada lying to the east and northeast of New York.

Until 1867 the Delaware & Hudson continued strictly a canal company so far as its transportation functions were concerned. Actually the canal soon began to operate as a common carrier for freight and, to some extent, for passengers. The records for 1830 show that it carried, among other commodities, 6,012 tons of merchandise, 3,383 tons of water cement, 1,255 tons of manufactured lumber, 75,022 cords of wood and 3,793,000 ft. of lumber.

The company transported this freight in addition to 43,200 tons of its own coal, comprising 1,706 boat loads. With this coal "388 sail of vessels" were loaded for cities and towns on the Hudson, in New Jersey, and the Eastern states.



The railroad part of the company's development began in 1867. On May 9, 1867, the Legislature of New

FIRST LOCOMOTIVE TO RUN ON TRACKS IN AMERICA

This, the "Stourbridge Lion," with its long pistons and walking beams, was brought over from England and run two or three times, on Aug. 8, 1829, over a short piece of track. The weight of the locomotive crushed the strap-iron rails into the hemlock timbers on which they were fastened to such a degree that the owners were afraid to put the engine into regular service. Its weight and rigidity made its operation on poor track dangerous. Note the exhaust pipe in the stack and the ineffectual cinder catcher. The locomotive now may be found in the Smithsonian Institution, in Washington.

NOTE—Headpiece shows the Loree breaker of the Delaware & Hudson near Scranton, Pa.

EARLY COAL CAR ON DELAWARE & HUDSON R.R.
No bigger than a large mine car. The gage was 4 ft. 3 in. but every feature of it seems designed to waste available space. The body does not overhang the wheels. The capacity of the car is 2.75 tons. It will be noted that it was provided with a bottom dump.

York amended its charter by empowering it "to construct, own and maintain railroads within this state, to contract with any railroad corporation now existing or hereafter to be created, for the use of its road, for the transportation of coal, to lease the railroad or any part thereof to any incorporated company now or hereafter to be created, upon which said canal company may desire to transport coal, and also to subscribe for and take stock or bonds of, and in, any railroad company which they may lease, or with which they may contract, now existing or hereafter to be incorporated. . . . " The new powers were to be used subject to the General Railroad Law of 1850.

By this act the Delaware & Hudson assumed the additional legal character of a railroad company, and from this beginning dates its interest in railroad construction but more especially in the leases by which it has acquired and now operates its line, running from a point a little south of Wilkes-Barre in Pennsylvania through to New York State, which it enters a little east of Binghamton, and thence continuing with sundry branch lines to Albany, Troy, Rutland and along the west side of Lake Champlain to the Canadian border, from which latter point the affiliated Canadian road extends as far north along the St. Lawrence as Quebec. As a natural consequence of its operation of this railroad line its primitive function as merely a coal carrier has been enlarged to include general freight transportation and a comparatively large passenger business.

When Anthracite Was Not Wanted

In these days, when the chief complaint about anthracite is that there is not enough of it to satisfy the needs of the consuming public, it is not easy to imagine the state of affairs when anthracite, first known as "stone coal," had no standing at all as a fuel and had to be urged upon a skeptical public with almost the same ingenuity and persistence employed now in marketing a safety razor. Only 115 years ago anthracite was, for all commercial purposes, unknown. Earlier than this, however, it was believed that Pennsylvania coal had merits, for at a meeting of the Susquehanna Co. in Windham, Conn., in 1763, the company reserved for itself, to be later disposed of, all beds or mines of coal in all towns which are assumed to be in the State of Pennsylvania, which the company then ordered to be settled.

In Pennsylvania records apparently the earliest reference to anthracite is the original draft of the survey of Sunbury Manor, made by Charles Stewart in 1768. On this draft "stone coal" is noted as having been found on Ross Hill. The earliest use of anthracite for which there is plausible authority seems to have been in 1792. In that year coal pits were opened at Weissport by the Lehigh Coal & Mine Co., and the "brittle compound" was then distributed free of charge to blacksmith shops willing to use it. For sixteen years afterward blacksmiths seem to have been the only users of anthracite, and then only when their shops were near the source of supply.

But on Feb. 11, 1808, Jesse Fell, in Wilkes-Barre, made the experiment of burning common stone coal in the Lackawanna Valley in a grate and found that it would burn. It was not until after the War of 1812, however, that the value of anthracite began to be appreciated seriously. Up to the beginning of that war bituminous coal had been imported from England, and this English coal together with wood and charcoal was the only fuel used for such manufacturing plants as were then in the United States. Not only did the War of 1812 interrupt for a time the importation of soft coal, but when importations were partly renewed the prices were excessively high.

Market Is Induced to Take a Ton a Day

It was about this time that a little anthracite was brought into Philadelphia from the nearer deposits, from which it could be floated down the Schuylkill River. The scantiness of the early production of anthracite is shown by an entry in the diary of Philip Hone, first president of the Delaware & Hudson, who noted, in November, 1839, that only 365 tons of anthracite was sent to the market in 1820. This came from the Lehigh region. He gave the total production in 1839 as over 1,000,000 tons. The fuel shortage in Philadelphia in 1814 was the initiating cause of the creation of the Delaware & Hudson Co., in 1823.

Beginning their search for anthracite apparently about 1814, the Wurts brothers had to undergo nearly ten years of arduous and sometimes rather costly pioneering before their scheme took on the actual promise of fulfillment. The rugged country of the upper Lackawanna was heavily forested and sparsely settled, and in their search for outcroppings of anthracite and their attempt to locate areas promising to supply large quantities of it they put up with what well might be called frontier hardships.

As early as 1816 they seem to have mined a small quantity of anthracite which they were unable to get to market. About 1822 they reached the site of the present town of Carbondale, gave it that name and made their settlement there, their party building the rough log house which was the first building in the town, later known as the Old Log Tavern. They had bought some coal lands, and at Carbondale in 1822 they opened a rude drift which later became the nucleus of the first mines of the Delaware & Hudson Co. By the autumn of that year they had mined at Carbondale nearly a thousand tons of anthracite.

The following winter, that of 1822-23, they succeeded in getting some of this coal to Philadelphia, carrying it part of the way on sleds and the rest of the way by rafts on the Lackawaxen and Delaware rivers—about one hundred tons in all. They managed to sell their coal, but seem to have found that the market was already more efficiently supplied with Lehigh coal, the first shipments of which had come to the city in 1820. This first transportation of their coal to Philadelphia

was accomplished only after great difficulties. They tried several different watercourses, and even in their final rafting down the Delaware some of their rafts went to pieces on rocks and much of the coal that they had loaded was lost.

Apparently the Wurts brothers had realized even before this attempt that the Philadelphia market would be difficult to reach and also that even when there they would meet the competition of the Lehigh and Schuylkill coal at a great disadvantage to their own product. In consequence, before the year 1823 they began to consider how they could reach the New York market.

Hill That Ramparted Wyoming Valley on East

To the east of Carbondale is a ridge 858 ft. above the present site of that city and 550 ft. above that of Honesdale, on the Lackawaxen River, which flows into the Delaware. In casting their eyes toward New York, the Wurts brothers discovered that New York was little more than a hundred miles away, and sundry explorations and map studies led to their developing the idea of taking their coal from Carbondale over the ridge to the Lackawaxen, canalizing not only that river to its junction with the Delaware but a short stretch of the larger river also, and then building from the Delaware a canal to the Hudson River.

Realizing that any such undertaking as this would be too much for their own resources, the Wurts brothers prepared maps of their coal properties around Carbondale and the relation of those fields to the Hudson River, and circulated these in influential business circles in New York City, hoping by this means to enlist support for their project. They also obtained from the Pennsylvania Legislature, on March 13, 1823, the passage of an act which authorized Maurice Wurts and others to canalize the Lackawaxen River.

This right to improve the Lackawaxen, together with possession of their coal lands, gave them something with which to approach New York financial interests. Although their plan to build a canal to bring their coal to New York was much criticized, the public was nevertheless strongly in favor of canal building. In consequence they obtained enough support that they were able to find signers to a petition urging their claims before the New York Legislature and to move that body to grant, in 1823, the charter of the Delaware & Hudson Co.

Engineer Plans Inclines and a Canal

That same year they engaged Benjamin Wright, who had been chief engineer of the Erie Canal, to make a survey of the line of the proposed canal from the Hudson River to the Delaware. Mr. Wright recommended a route, together with details of construction, and estimated the cost at about $1,300,000. Under Mr. Wright's plans a canal was to be used to furnish a highway from the Hudson to Honesdale on the Lackawaxen, and a railway was to be built to cross the ridge between Honesdale and Carbondale. This latter, when built, formed the famous gravity railroad.

Further legislation by the State of Pennsylvania authorized the Delaware & Hudson Co. to acquire the rights of the Wurts brothers in the canalizing of the Lackawaxen River, and the whole project was then in a state to present to investors.

It was not until January, 1825, that subscription books to the company's stock were opened, in the Tontine Coffee House, at the northwest corner of Wall and Water Streets, and at two other places. The capital stock of $1,500,000 was quickly oversubscribed. On March 8, 1825, again at the Tontine Coffee House, in New York, the first board of managers of the Delaware & Hudson Co., consisting of thirteen members, was elected. On March 9 these managers organized and on March 11 elected Philip Hone as president of the company and John Bolton as treasurer.

The election of Mr. Hone gave the new Delaware & Hudson Co. much prestige, for he already was prominent in the business of the city and had acquired what was for those days, a comfortable fortune. He had wide and influential connections both socially and politically. He had retired from active business in 1820 at the age of 40. At that time he lived in a house at No. 235 Broadway, near the corner of Park Place, where now stands the Woolworth Building. In 1824 Mr. Hone was elected as Assistant Alderman of the City of New York, and in 1826 Mayor of the city, which office he held for one year. In 1816 he had been appointed by the Legislature a trustee of the first savings bank established in this country, and he was officially prominent in many other institutions. Politically he was a strong Federalist, and later a Whig, being credited with having given that name to the party. Work began on the canal July 13, 1825.

SUMMER COACHES ON GRAVITY RAILROAD

These coaches have the look of American street cars with their open side and long seats. They were fitted for use only during the warm summer months, when pleasure rather than business was the reason for travel.

Until March, 1825, the Delaware & Hudson Co. had no office in New York, but having been authorized by the Legislature in the preceding November to use $500,000 of its capital in transacting a banking business, it bought No. 13 Wall Street and there opened the Delaware & Hudson Canal Company Bank, which was conducted at that spot until 1844, when the twenty-year period set by the charter of the Legislature came to an end. The new bank stood on the north side of Wall Street just east of Nassau on ground now covered by the United States Sub-treasury. It was directly across the street from the present site of the banking house of J. P. Morgan & Co.

By the winter of 1826-1827 it began to be clear to the managers of the Delaware & Hudson Co. that Wright's estimates of cost for the canal were too low, and it was then determined to ask the State of New York for aid. As the result of the company's appeal the act of March 10, 1827, authorized the issue of $300,000 of state stock in the canal company, for which loan the company was to pay interest at the rate of 5 per cent. A second state aid, of $200,000, was authorized by the act of May 2, 1829, to carry interest at 4½ per cent. These two loans were repaid by the Delaware & Hudson

Co. at their respective maturities, Jan. 1, 1848, and Jan. 1, 1850.

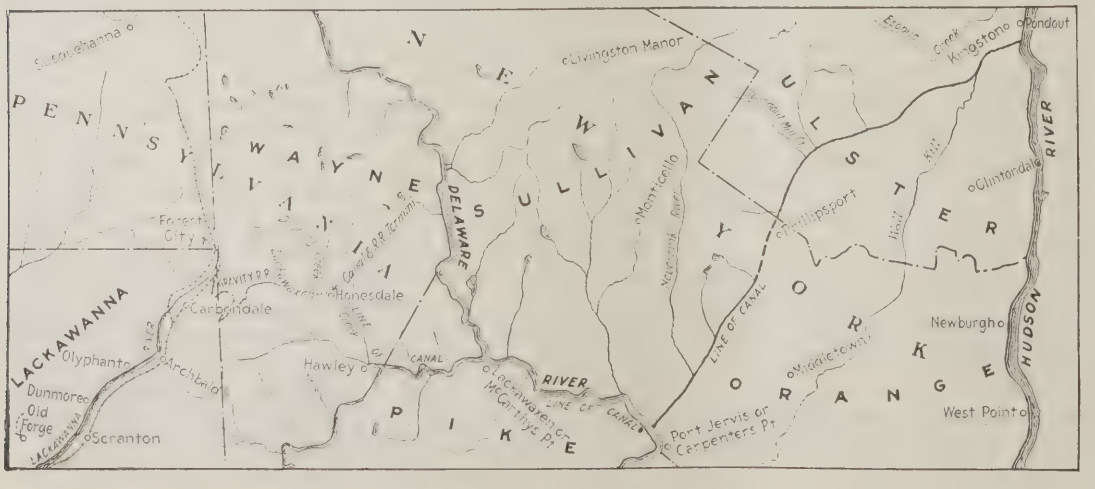
Following this grant, the first financial assistance of the State of New York to projects of this character, contracts for the entire length of the canal were let, in April, 1827, and construction was energetically resumed. The canal was completed in the autumn of 1828 and the first squadron of canal boats, from Honesdale, passed through the canal and arrived at Rondout, the Hudson River terminus, on Dec. 5, 1828.

The *Albany Argus* of Dec. 13 of that year gives this description of the canal, remarking that fifty tons of the first shipment of coal "had been consigned to the Messrs. Townsend, which will afford our citizens an opportunity of testing its quality."

"This canal," continues the *Argus*, "is 32 to 36 ft. wide upon the water line and is 4 ft. deep. The locks are 76 ft. in length between the gates and 9 ft. wide, and the coal boats are estimated to carry 25 to 30 tons.

"From the mouth of the Rondout, where it connects with the Hudson, to Port Jervis, near the Delaware River, is a distance of 59 miles; on this section are 60 lift locks and one guard lock of hammered stone laid chiefly in hydraulic cement. There also are one aqueduct over the Neversink River, 234 ft. in length, upon stone piers and abutments; one over the Rondout entirely of stone, upon two arches, one of 60 and the other of 50 ft. chord, and ten others of various dimensions, upon stone piers and abuttments over lateral streams; 15 culverts of stone, and 95 bridges having stone abuttments and wing walls.

"Port Jervis is less than a mile from Carpenter's Point, formed by the junction of the Neversink and Delaware rivers, and at which point the States of New York and New Jersey corner upon Pennsylvania. Port Jervis presents a view of the territory of three states, and also of the Delaware River and the fertile valley of the Neversink. From this point the line of the canal is carried along the east side of the Delaware to a point opposite the mouth of the Lackawaxen River. At this place a dam has been erected across the Delaware, by means of which the canal is fed and boats cross the river. From McCarthy's Point, which is formed by the junction of the Lackawaxen with the Delaware, the canal follows up the valley of the Lackawaxen, 25 miles to the forks of the Dyberry, at which point the canal terminates and where a thriving village is already established called Honesdale.



"On the Delaware section of 22 miles there are 15 wooden locks, and on the Lackawaxen section of 25 miles are 37 locks of the same description. These locks are secured by a substantial dry stone wall, and so constructed that the wooden lining can be taken out and replaced without disturbing the rest of the lock."

Though the canal afterward was greatly enlarged in capacity and the depth of water increased so that boats of nearly 200 tons capacity finally were used, to the public of this day the most interesting item in these changes probably is the four suspension aqueducts which were constructed in 1849 as the culmination of the improvements made during the forties. John A. Roebling, whose name has since become inseparably linked with the construction of the first Brooklyn Bridge, suggested the plans for these aqueducts, constructed them, and supplied the cables. By these aqueducts the canal was carried across the four rivers, those crossed from east to west being the Rondout, the Neversink, the Delaware and the Lackawaxen. The Delaware aqueduct was carried on wire cables 8½ in. in diameter.

Provision was made for passenger traffic on the canal by the building of two packetboats with accommodations for twenty passengers, meals being supplied on board. An advertisement of this service, which began Oct. 7, 1829, as published in the *New York Morning Courier and Inquirer*, shows that the fare from the eastern terminus, near Kingston, to Honesdale, was $4. The charge for way passengers was 5c. a mile. The westbound boat left the eastern terminus at 7 a.m. and the eastbound boat left Honesdale at 6 a.m. on Mondays, Wednesdays and Fridays, making the whole trip in 36 hours. Mr. Hone's diary gives the details of some trips he made over the canal in this fashion.

The gravity railroad, by which coal was taken from Carbondale over the 858-ft. ridge to the east and thence down to Honesdale on the Lackawaxen, where the coal was put aboard canal boats, consisted of a series of fairly steep inclines, alternating with level or slightly descending sections operated by horses. The inclined planes were first constructed with a single track and turnouts, but in the middle of each plane was a stretch of 100 to 150 ft. of double track, so as to permit of cars passing in opposite directions.

These turnouts were provided with self-acting switches, so that whenever a car passed out of the turnout in either direction the switch was left in such a position as to turn the next car moving in the opposite direction into the side of the turnout thus vacated. On the west side were five long ascending planes with a stationary steam engine at the head of each plane. By means of a long chain extending the entire length of the

Gravity Railroad and Canal

From Carbondale engine planes raised the cars to the summit and gravity planes lowered them to Honesdale. There the coal, dumped into a boat, was floated by canals along the Lackawaxen and Delaware to Port Jervis and thence by another canal to Rondout on the Hudson.

MARVINE BREAKER, WHERE THE COAL IS BROUGHT FROM TWO ROCKHOUSES FOR FINAL PREPARATION
This breaker, which prepares 5,000 tons per day, was started in 1920. Interesting features are the concentrating tables, thickeners and separators and the long conveyor lines connecting the breaker with the two shafts, which are 2,000 ft. apart. The coal receives its preliminary treatment before being taken to the breaker itself.

plane these engines hauled up from three to five loaded cars (each car carrying about 1,500 lb. of coal) and at the same time let down the same number of empty cars which were attached to the other end of the chain.

On the eastern side of the ridge, for the descent toward Honesdale the three descending planes were worked by the force of gravity, without the use of steam; the descending loaded cars drawing up the ascending empty cars attached to the other end of the chain, the speed of their descent being controlled by the use of friction brakes on the shaft of a large upright fan-wheel, which thus furnished braking power by working against the resistance of the air. This original and simple scheme later was much modified, the number of planes from Carbondale to the canal subsequently being increased to eight.

In later years, as the company's mining operations were extended south to Carbondale, the gravity railroad was extended southward as far as Olyphant, and the eastbound, or loaded, and the westbound, or light, tracks were separated, so that in the later arrangement the loaded track had on the east side a single inclined plane into Honesdale somewhat more than ten miles in length. The light, or westbound, track for empties was relocated, taking advantage of the topography, so as to give a nearly uniform line of descent, on which the cars ran by gravity alone from the summit nearly to Archbald, south of Carbondale, in the Lackawanna Valley, a distance of about 13 miles.

Beginning in the summer of 1860 passenger traffic over the gravity railroad in the Lackawanna Valley made a small beginning, and in later years this developed largely, the trip over the ridge being considered quite an excursion. Later John B. Jervis succeeded Benjamin Wright, the planner and engineer of the canal, as chief engineer. He planned to use steam locomotives, then unknown in America, to haul loaded cars down and empty cars up the easy descending planes, as had been suggested when the gravity railroad was first designed.

It was Jervis' recommendations that led the company to send to England in January, 1828, Horatio Allen, a young man of twenty-six, to arrange for the building of four locomotives and also to obtain iron for capping the wooden rails of the roadway. In terms of locomotives, the results of Allen's mission were the locomotive America, designed and built by George Stephenson, the builder of the famous Rocket, and three locomotives of a different type built by Foster Rostrick & Co., of Stourbridge, England.

Stephenson's engine, the America, was the first steam locomotive to be seen in the Western Hemisphere. It arrived at the port of New York on the ship Columbia on Jan. 15, 1829. The engine was taken to the yard of Abeel & Dunscomb, at 365 Water Street, where it was put together, supported on blocks so that the wheels ran free, and then demonstrated under steam from time to time during some three months, many visitors coming to see the wheels go round. Later in the season the America, together with the first of the Foster Rostrick locomotives, was shipped by way of the canal to Honesdale, and from that point all authentic trace of it has been lost until within the past few months.

The second locomotive, which arrived on May 14, 1829, was the Stourbridge Lion, the first steam locomotive to run on rails in America. Like the earlier arrival, the Lion was assembled and set up on blocks in the machinery works of William Kemble and was demonstrated under steam, as the America previously had been. The two locomotives remained in New York until about July 1, when they were sent by sloop up the Hudson to the eastern terminal of the canal, then called Eddyville but in recent years known as Rondout. There they arrived on July 4, reaching Honesdale a few days later.

For some reason not now clear Horatio Allen, who had ordered the two locomotives in England and who was in charge of making the first test on the rails of the gravity railroad, selected the Stourbridge Lion, and early in the forenoon of Aug. 8, 1829, that locomotive was drawn up an inclined plane which had been laid from the side of the canalboat to the railroad track. A fire was built in the firebox with Lackawanna coal, and the steam pressure soon moved to a point sufficient for the trial.

It had been the intention of Mr. Jervis that the locomotive should not put more than 1½ tons of weight on each of the four wheels, but when the Lion's boiler was filled with water the locomotive was found to weigh over seven tons, two-thirds of which rested on the forward wheels, with the result that the weight on these two wheels was about double that which Mr. Jervis had expected. Some critical observers on learning of this excess of weight predicted that the engine would break down the track on the curved portions of the trestle work by which the road was in places supported, while others, noting that the four wheels were rigidly set on the frame, declared that on curves the driving wheels would climb the outer rail and jump the track.

As these gloomy predictions seemed plausible, Mr. Allen declared he would risk his own neck on the trial, and he, thereupon, acted as engineer, driving the Lion two or three times back and forth over a section composed of straight track and of a curve of 700-ft. radius,

crossing the Lackawanna Creek on a trestle 30 ft. high. The track did not break down and the engine did not climb the rails and jump off, but the result of the test as read afterward in the condition of the wooden rails and the trestles convinced the engineers that the structure would not withstand either the weight of the Lion or the sidethrust of the wheels on curves.

A little later the engineers considered whether it would be possible to rebuild the supported parts of the railroad and the curves in a more solid fashion to withstand the load, but for various reasons this was decided to be impracticable. The Lion was then taken off the tracks, set to one side, and for some fifteen years neglected, and, there is reason to think, partly dismembered, until many years later nearly all its parts were recovered in various places and assembled in the National Museum at Washington. The two sister locomotives of the Lion were received in New York, but owing to the difficulties encountered in the test of the Lion, no attempt apparently was made to use them.

The "Gravity Road" was relocated and improved in 1832 and in 1846 it was practically rebuilt, the location of the inclines being revised and a second track added, this being an independent line with the necessary inclines, one road being known as the "Loaded Track" and the other as the "Light Track." Other modifications were made from time to time, but the "Gravity Road" continued in existence as such and was used for both freight and passenger business until 1899, when it was largely rebuilt and the gage widened to 4 ft. 8½ in., the former gage being 4 ft. 3 in.

At that time regular operation by steam locomotives commenced. The company extended its "Gravity Road" southward from Carbondale along the Lackawanna Valley in 1846 to a point near Archbald, Pa., where the company had purchased additional coal lands, and in 1858 it was extended to a point known as Valley Junction, near Olyphant, Pa. The road was further extended to Providence in 1861 and to Green Ridge in 1863, these last two extensions being operated by locomotives. A portion of the final extension is now the Vine Street Branch in the City of Scranton. The Poplar Street Branch, in the same city, was partly built in 1867 and completed some time prior to 1877.

In 1871 a steam-operated railroad was constructed from Valley Junction northward to Carbondale, practically paralleling a portion of the Gravity R.R. The Jefferson R.R. between Carbondale and Jefferson Junction, built by the Erie, was operated under a trackage agreement, the Delaware & Hudson Co. building its own line from Jefferson Junction to Nineveh in 1871. At the latter point connection was made with the Albany & Susquehanna R.R., which had been constructed between Binghamton and Albany between the years 1863 and 1869.

This latter railroad was leased by the Delaware & Hudson Co. on Feb. 24, 1870, giving the company an entrance into Albany. The Cherry Valley Branch, between Cherry Valley and Cobleskill, came into possession of the company on June 1, 1870. These two lines added 164 miles. By a lease dated May 1, 1871, the Rensselaer & Saratoga R.R. and a number of lines that company had leased came into possession of the Delaware & Hudson Co., which extended its line from Albany and Troy to Whitehall, to a connection with steamers on Lake Champlain, with branches from Fort Edward to Glens Falls, from Schenectady to Ballston, from Whitehall to Rutland and from Eagle Bridge to Castleton. These lines were built beginning as early as 1832 and gradually extended and enlarged between that date and 1869. These lines added about 190 miles to the system. A connection with the leased property acquired from the Rensselaer & Saratoga was constructed between Delanson and Schenectady in 1872 and upon completion was acquired by this company by lease, and was merged into the Delaware & Hudson Co. in 1903.

In 1867 a railroad had been constructed southerly from Green Ridge, now a part of the city of Scranton, to a point near Wilkes-Barre by the Union Coal Co. which afterwards, in 1873, was leased to this company. This line was further extended in 1886 to Wilkes-Barre, and in the intervening years branches were acquired in the Plymouth district, where extensive mines of the company were located.

CARBONDALE YARDS WHERE THE COAL IS ASSEMBLED BEFORE BEING DISPATCHED OVER THE HILL TO MARKET

Chance has much to do with early development. The Wurts brothers, seeking to get coal for Philadelphia, looked too far north and found themselves in a territory better suited to supply New York and Albany than the city to which they expected to deliver coal. They soon realized their mistake and directed their efforts to reaching the cities on the Hudson River. After all, the northern end of the Shickshinny-Forest City basin was perhaps about as well situated as any point in the anthracite region for that purpose. Out of their venture came Carbondale and the thriving boroughs to the south.

General Availability and Excellent Quality of Hazard Coals in Eleven Years Make Field Large Producer

Extent and Geological Features of Region—Main Output Comes from Seams Nos. 6 and 4—Coal Is Low in Ash and Sulphur—Ash Fuses Only at High Temperature—Leasing System Aids Rapid Development of Field

By W. Norris Cole
Mining Engineer, Kentucky River Coal Corporation, Hazard, Ky.

As a result of the strike of the coal miners last summer the importance of the Hazard coal field to the nation at last was clearly demonstrated, for it is one of the leading non-union coal areas of southeastern Kentucky. It derives its name from the town of Hazard, the county seat of Perry County, that municipality being situated in about the center of the long southwestern line of the field.

The coal area comprises about 350 square miles and is situated in Perry, Knott and Letcher counties. It is bounded on the north by Lost and Troublesome creeks, on the east by Sandlick Creek and on the south and west by the North Fork of the Kentucky River. (See Fig. 12.)

A mountainous country, having narrow valleys, steep hillsides and innumerable creeks and streams, the field could not be developed properly without the construction of long spur railroad tracks which run up the largest of these creeks from the main line which winds its way on the edge of the field, following the Kentucky River. There are now seven of these main spur lines, which follow First Creek, Lotts Creek, Buffalo Creek, Carrs Fork, Rockhouse Creek, Smoot Creek and Sandlick respectively. The last mentioned of these seven streams forms the boundary between the Hazard and Elkhorn fields, but both the Hazard and Elkhorn coals are mined along the course of this stream. From these main spurs radiate the individual sidetracks of some eighty different operations, each producing from three to sixty cars of coal per day.

The lowest seam is known locally as No. 4 bed. It underlies the entire territory, being quite low in the series. In the state geological report it is known as the "Fireclay" seam, because it contains a persistent parting of from 3 to 6 in. of flint clay called the "jackrock." This readily distinguishes it from the other beds. Some of the operators correlate it with the well-known No. 2 Gas seam of West Virginia.

Its thickness varies from 30 in. to 6 ft. and averages throughout the field about 42 in. Where the seam thins down to 36 in. or lower the "jackrock" forms the bottom, but where the coal is thick the upper bench is

FIG. 1—TIPPLE OF BLUE DIAMOND COAL
This structure spans First Creek. The mine is working the No. 6 seam. The dump-house can be seen in the upper left-hand corner of the illustration.

Note—Headpiece shows tipple of Dudley Coal Co., Blackey, Ky. This tipple spans Caudills Branch. At the left can be seen a steel pipe which is used for lowering coal down the mountain to the tipple. The latter is securely braced between the opposing hillside.

FIG. 2

Tipple of First Creek Coal Co.

This tipple is located at Dowlais, Ky. The coal is brought down an even trestled grade from the dump-house high on the hill, so high in fact that the area mined must be of the many-fingered shape frequently found in this field.

about 42 in. thick and the lower bench is below the "jack."

This No. 4 seam produces an excellent steam and domestic coal that is hard enough to stand shipping well and has a bright luster of a bluish cast. Consequently it makes an excellent appearance. It is low in ash and sulphur, and the ash melts only at a high temperature; consequently it is practically clinkerless even when the furnace fires operate under forced draft. Furthermore it is a good byproduct and gas coal, and in composition it closely resembles the coal of the famous Elkhorn seam, as the following analysis of the product from the two fields will show:

PROXIMATE ANALYSIS OF NO. 4 ELKHORN SEAMS

	No. 4 Hazard Per Cent	Elkhorn Per Cent
Fixed carbon	58.37	60.53
Volatile matter	36.97	35.02
Moisture	1.42	1.53
Ash	3.24	2.90
Sulphur	0.61	0.44
British thermal units	14,482	14,421

About 235 ft. above the No. 4 seam is the No. 5, or Haddix, bed, which apparently is not as persistent as No. 4. It lies immediately below a massive sandstone ledge from 30 to 40 ft. thick. I know of only two openings in this seam where the coal has been worked and there only to a small extent. One is near Yerkes and one on the north side of Troublesome Creek. In both these openings the seam is 36 in. thick, free of partings and of excellent quality. Immediately above the sandstone ledge is the 5A, or Young, seam, which varies in thickness from 36 to 54 in. Like No. 5 seam it has not been much prospected. At Domino, on the Kentucky River, a pair of entries were driven on the Himyar Coal Co.'s property for the purpose of testing the bed and for obtaining house coal. It varied from 36 to 48 in. in thickness and had a small parting which did not appear to be persistent. The coal was of excellent quality, resembling that of the No. 4 seam. On First and on Lotts Creek and also on Hensons Branch the bed is about 50 in. thick with from 8 to 10 in. of fireclay parting near the center of the seam.

About 60 ft. above the No. 5A, or 350 ft. above the No. 4 seam, is the No. 6, or Hazard, seam. At the present stage of development this is commercially the most important seam in the Hazard field, as from it is produced by far the greater quantity of coal coming from this region. It varies in thickness from 4 to 7 ft. and has an average thickness of about 5 ft. over the larger part of the field. The principal operations in this seam are on First Creek and Lotts Creek, where the

FIG. 3

No. 6 Seam at Dowlais

This is the principal bed in the Hazard field, that from which most of the coal comes. Its thickness varies from 4 to 7 ft., and here it is not much less than the higher figure. Yet despite its thickness it is a clean seam from the bottom to the slightly rolling top. The illustration shows the end of a room in the First Creek Coal Co.'s mine at Dowlais, the underground workings subsidiary to the tipple shown in Fig. 3.

FIG. 4

Surface Works at Staub, Ky.

Plant of the Hazard-Jellico Coal Co. on First Creek. No. 6 seam, which is at tipple height, is mined on both sides of the valley, the coal being brought in cars to dumps near the center of the tipple. The chute and supply track in the rear-ground and to the right of the tipple descend from the level of No. 8 seam. This bed is of minable thickness in the high hills of Lotts Creek and Carrs Fork. The two seams are about 150 ft. apart.

bed is at its best, its thickest manifestation being on the stream first mentioned.

The seam varies in character as much as it does in thickness, being different at nearly every operation. It has a persistent bone parting from 1 to 3 in. thick and located from 3 to 15 in. from the bottom, being thickest where the seam is thick. In certain localities other partings of bone come and go but do not persist over any large area.

The coal in this seam is hard and blocky and has made an excellent reputation as a domestic coal wherever it has been introduced. It will stand frequent rehandling without much deterioration. It also stocks well. A lump of this coal taken from an old country pit after it had been lying out on the ground more than six years was sawn in two and, except for the weather stains on the outside, was found to be as black, hard and solid as a piece just taken from the mine. Furthermore the lowness of its sulphur content, about 0.56 per cent, aids in reducing the danger of spontaneous combustion.

A characteristic analysis of this seam is as follows:

PROXIMATE ANALYSIS OF NO. 6 OR HAZARD, SEAM

Fixed carbon	56.32
Volatile matter	37.16
Moisture	1.92
Ash	4.60
	100.00
Sulphur	0.56
British thermal units	13,823

From 60 to 70 ft. above the No. 6 seam is the No. 7, or Flagg, seam, averaging 52 in. in thickness with a 1-in. bone parting about 15 in. from the bottom. Though this parting is high in ash it is combustible. It is now thrown out in the shipment of the coal, but under normal market conditions it has been accepted by the trade without complaint.

The No. 6 and No. 7 seams are quite similar in character, and the fact that the two seams are seldom found workable in the same locality has led some engi-

No. 1 headhouse with tipple for Mines Nos. 1 and 2. This mine is located at Blackey, Letcher County, Ky., at the mouth of Rockhouse Creek. It will be noted that it also has a steel tube for letting the coal down the hill. The road up the hill to the right of the illustration is the supply track. The tipple crosses the creek and serves the coal areas on either side.

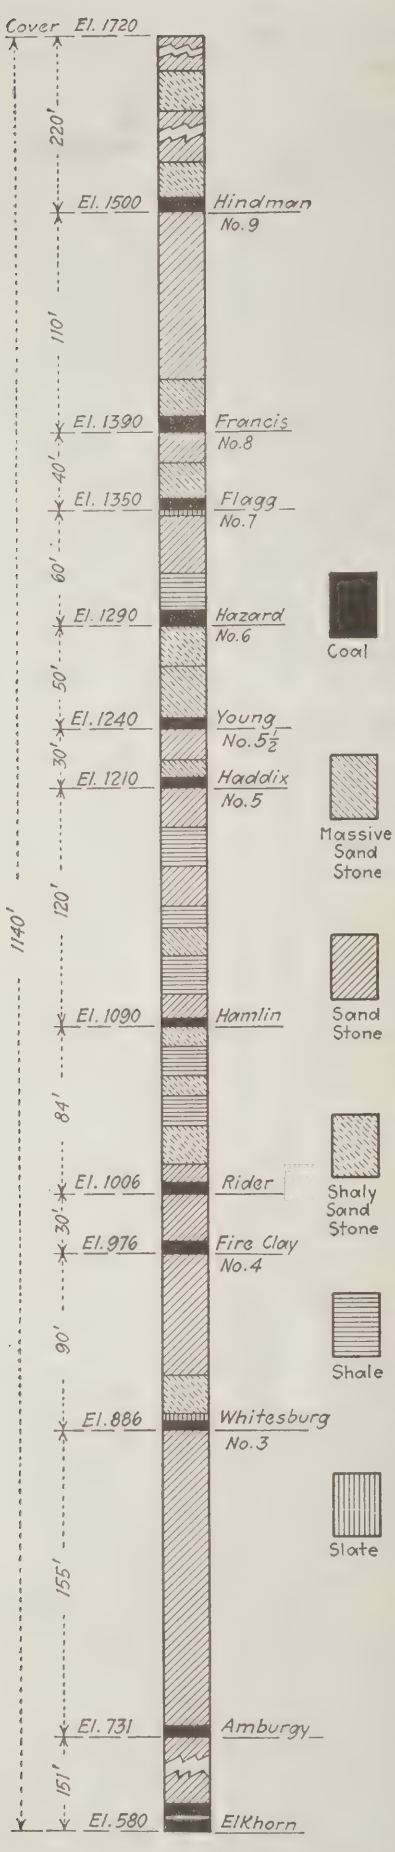

FIG. 6—HAZARD SERIES

The principal beds are No. 6 and No. 4, the "Hazard" and the "Fireclay" seams respectively.

neers to believe that they are the same seam. However, insufficient investigation has been given to the matter to determine finally which view accords with the fact. As the two are only 60 ft. apart and as local dips and rolls make their levels inconsistent in any given direction, it is easy to account for the belief that the two seams are identical. It is still possible that the assumption is justified. There is another seam of coal above the No. 6 seam on both First Creek and Lotts Creek. The thickness of this bed varies from 40 to 60 in. but it is so split up by numerous partings as to render it unminable. At Harveyton, on First Creek, and at Domino, on the North Fork of the Kentucky River, this seam has the cross-section shown in a table in the succeeding column. At Lothair and Glomawr, where seam No. 7 is workable, a bed of coal lies about the same distance above that seam as in First Creek and Lotts Creek. It has about the same characteristics as seam No. 8. At these points also a seam appears with about the same interval below seam No. 7 as is found between that bed and No. 5A on First and Lotts creeks although neither of these two seams has been sufficiently prospected to determine definitely their nature and sections. About 150 ft. above the No. 6 seam is the No. 8 seam. This is of minable thickness only in the high hills on Lotts Creek and Carrs Fork. On Lotts Creek its thickness ranges from 50 in. to 6 ft. It has

FIG. 7—LOADING BOOM, FIRST CREEK COAL CO.

A sample of the coal from the seam shown in Fig. 3 after it has been broken up and the fines screened out. The ability of the coal to withstand hard usage is quite evident.

been worked by the Hardy-Burlingham Mining Co. for the last three years. At this company's mines the seam is about 6 ft. thick. It also is operated by the Wisconsin

This is in operation at the mine of the Dudley Coal Co. Some of the refuse can be seen in the foreground.

FIG. 9

No. 4 Seam at Caudills Branch

This bed shows two characteristics that differentiate it from seam No. 6 in Fig. 3. The roof is as smooth as if polished, and the well-known "jackrock" shows at about pick-handle length above the floor. This "jackrock" is a persistent parting measuring from 3 to ¼ in. and is of flint clay. Scene is from the Dudley Coal Co.'s operation, David near Blackey, Ky.

The development of the Hazard field has been rapid. The first coal was shipped from the village of Hazard and was mined from the No. 4 seam. This was in the autumn of 1912. In 1919 the tonnage had risen to 2,400,000, and during the month of June, 1922, shipment was made of 686,500 tons of coal by the mines having railroad connections. This output would be equivalent to 8,238,000 tons annually. There are now some eighty different operations, exclusive of wagon mines, ranging in capacity from 3 to 60 cars per day.

Most of these mines have modern and up-to-date equipment, both inside the mine and above ground, for cutting, loading and cleaning the coal. They are equipped with retarding conveyors, shaking screens, picking tables and loading booms and are prepared to turn out a first-class product.

The mines are all electrically equipped and power is being supplied by the Kentucky & West Virginia Power Co., located at Lothair, which is about in the center of one side of the field. This company has had to enlarge the capacity of its plant several times since its installation but as a rule has anticipated its needs so as to give comparatively litttle trouble to its consumers. The present capacity of the local plant is 16,000 kw. It is planned to couple this plant with those at Logan and Williamson, in West Virginia, in such a manner as to make practically one plant of the three units so that in case of a breakdown at any one of the plants another can be thrown into the circuit until the trouble is corrected.

The field was aided in its development by the fact that most of the area is owned by land companies and leased to operators on a royalty basis. This enables the small financier to start his mine with only sufficient capital to put up the plant. The lessors also have assisted in financing the construction of the railroad spurs up the main creek, the operator, of course, putting in the sidetrack for his own mine.

Among the largest of these companies is the Kentucky River Coal Corporation, which owns about 140,000 acres of land in Perry and adjoining counties. This company has been particularly aggressive in advertising

FIG. 10—PUMP STATION, KENTUCKY RIVER POWER CO.

The long conveyor of the Algoma Mine, of the Algoma Block Coal Co., can be seen in the rearground. This station is at Lothair, Perry County, Ky., and was under construction when photographed.

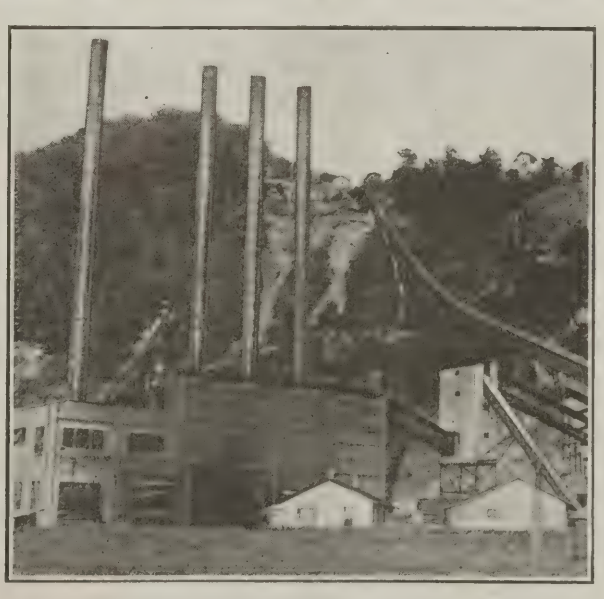

FIG. 11—POWER HOUSE OF THE KENTUCKY-WEST VIRGINIA POWER CO., LOTHAIR, KY.

Here also may be seen the conveyor of the Algoma Mine. Power plant has four alternators of 20,000 kva. total capacity, generating 3-phase 60-cycle current at 2,300 volts. This is stepped up to 11,000 volts. The boiler horsepower is 2,500.

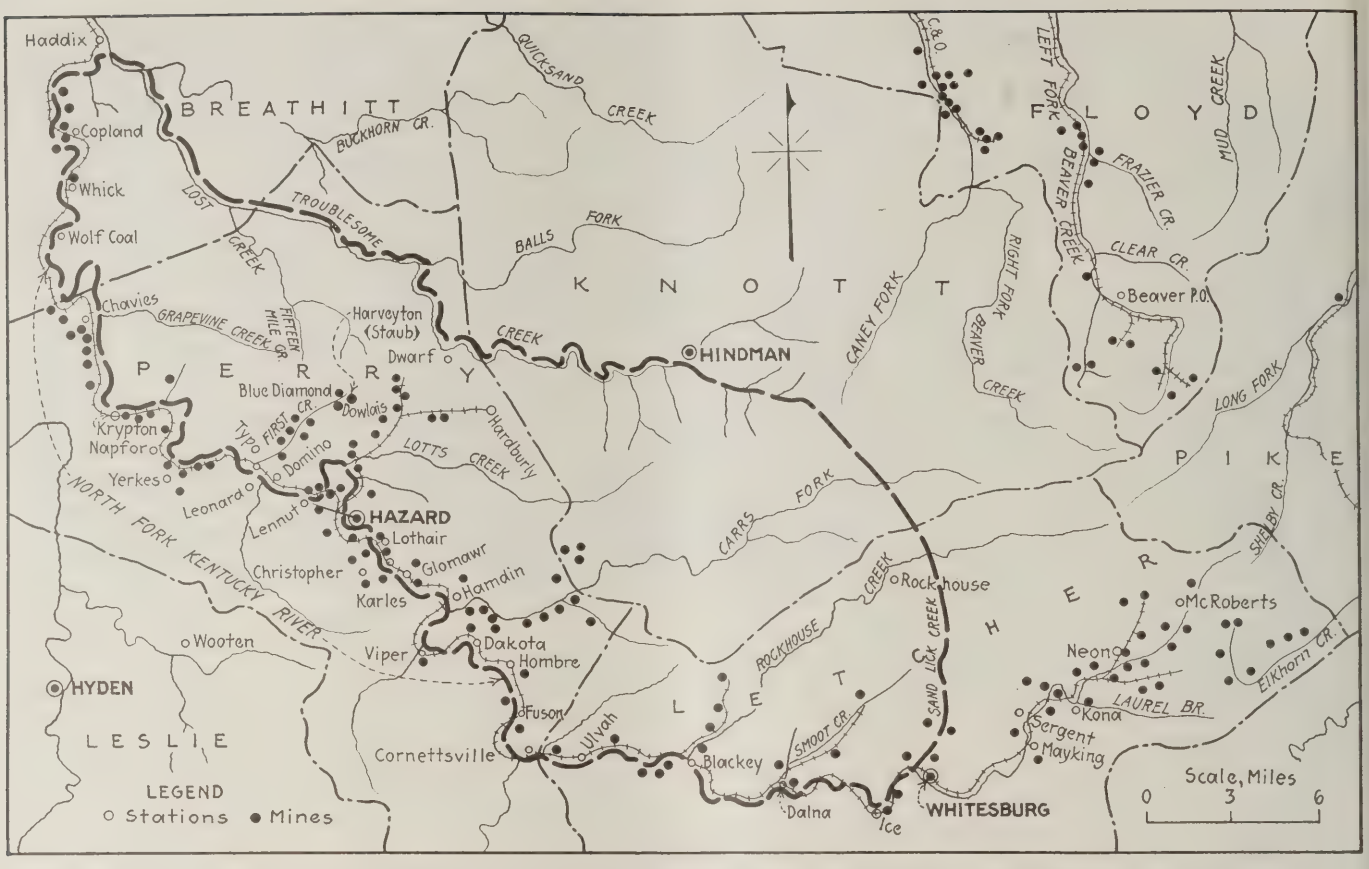

FIG. 12—HAZARD COAL FIELD LYING TO THE NORTH OF KENTUCKY RIVER FROM WHITESBURG TO HADDIX
The field lies in Perry Knott, Letcher and Breathitt Counties, in Kentucky. It has been attacked from the Kentucky River and from the affluents of that river south of Haddix. No railroad has been constructed up Lost and Troublesome Creeks, which bound the coal area to the north. The map extends into the Floyd County, or Paintsville, and the Elkhorn fields, without however, recording their boundaries.

the qualities of the coal and in bringing in outside capital, and as a result of this policy thirty-three of the operations are on the land of that company and about 60 per cent of all the coal shipped from the Hazard field is from these operations.

This company also maintains an engineering and inspection department and though the primary object of this force is to see that the coal is so mined from the company's leased land as to recover the greatest possible quantity of coal per acre mined, it has been of valuable assistance to the individual operators in planning with them the system that will be best suited to the conditions found at their mines.

As soon as the operators recognized the fact that this department was to be conducted on a policy of helpfulness as well as of criticism they gladly co-operated with it, and, as a result, the mines will compare favorably with any like group of operations in the country.

The town of Hazard also has shared in the rapid growth of the field. Starting in 1912 from a little village of 500 people, it is now a flourishing city of 8,000 population with paved streets and good schools.

Sales of Explosives in 1922 16 per Cent Greater Than in Preceding Year

Sales of explosives in the United States during the calendar year 1922 was greater by more than 16 per cent than the amount sold in 1921, according to reports received by the Bureau of Mines, which show that the total sales amounted to 431,772,077 lb. as compared with 372,107,503 lb. the year before. Of the total amount sold 178,866,225 lb. was black blasting powder, 209,476,084 lb. high explosives other than permissible explosives, and 43,429,768 lb. permissible explosives.

In 1922 the coal mines used 6,190,478 kegs, or 154,761,950 lb. of black powder, as compared with 5,613,435 kegs, or 140,335,875 lb. in 1921. In 1922 the coal mines used 25,497,758 lb. of high explosives other than permissibles, as against 34,231,542 lb. used in 1921. The coal-mining industry in 1922 used 43,429,768 lb. of permissible explosives compared with 38,055,650 lb. of permissibles used in 1921.

Pennsylvania, as usual, was by far the leading state in the consumption of explosives, having used 18,669,539 lb. of permissible explosives, 31,509,040 lb. of high explosives other than permissible, and 1,169,690 kegs of black blasting powder. West Virginia was second in the use of permissible explosives, with a consumption of 8,552,719 lb.; Alabama was third, with 4,292,969; and Illinois was fourth, with 2,758,300 lb.

Sales of explosives during January, 1923, amounted to 816,693 kegs of black powder, 5,376,370 lb. of permissible explosives, and 16,425,242 lb. of other high explosives.

Sales of black blasting powder in January were 61 per cent more than in January, 1922 and 69 per cent in excess of January, 1921, but were 9 per cent below the sales recorded for January, 1920. Of the quantity of black powder sold in January of the current year, 91.7 per cent was for coal mining.

Sales of permissibles in January were 92 per cent in excess of those for January, 1922, 36 per cent more than in January, 1921, and 20 per cent more than in January, 1920. Of the total quantity of permissibles sold in January, 1923, 94.2 per cent was for coal mining.

The January, 1923, sales of high explosives represent an increase of 47 per cent over January, 1922, 40 per cent over January, 1921, and 6 per cent over January, 1920. Coal mining operations used 19.4 per cent of this class of explosives sold in January, 1923.

Synchronous Motor-Generator Sets May Supplant Rotary Converters for Coal Mines

Comparison of Relative Stability of Both Machines—Ease of Installation and Method of Control—Ability to Correct Lagging Power—Factor an Important Economic Question

By Edgar J. Gealy
Electrical Engineer; Associate Editor, *Coal Age*

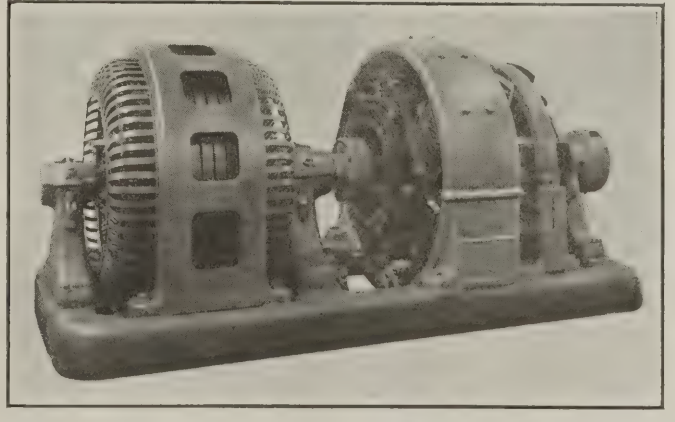
FOR evidence of the fact that the question as to whether the synchronous converter, more popularly called rotary converter, or the synchronous motor-generator set is the best machine for use about the coal mines for converting alternating current to direct current one need only make a short survey through the power plants and substations of the coal field or go over the numerous orders recently placed for such equipment. After such a survey one would find that few companies have all synchronous converters and no synchronous motor-generator sets or vice versa, indeed he probably would find at the same operation both synchronous converters and synchronous motor-generator sets and no doubt would find both types of machines among the new equipment being installed.

The latest development in substations is the automatic substation and even here we find both synchronous converters and synchronous motor-generator sets. Since these automatic substations generally are completely engineered by the manufacturer we are almost forced to believe that the manufacturer himself has this big question: namely, synchronous converters versus synchronous motor-generator sets, in his mind.

Advantages of the Two Types of Machine

For the synchronous converter almost anyone will argue as advantages such points as high efficiency, one armature winding, small size for a given capacity where its transformers may be mounted outside a building and availability of a neutral connection for the direct-current end for use in charging storage battery locomotives, thus effecting great economy compared with charging direct from the trolley line.

However, from advantages inherent in the machine itself and the trend of developments about the coal fields from the viewpoint of location of substation, kind of load, more extensive application of induction motors, tendencies toward changes in power contracts, etc., the synchronous motor-generator set seems to be the best type of machine for converting alternating current to direct current.



Without attempting an exhaustive comparison between these two types of machines it would be interesting no doubt to list and look into a few of the advantages and disadvantages of both types of machines.

It is a recognized fact that the synchronous converter is less stable in operation than a synchronous motor. Slight changes in the control or methods of operation of the synchronous converter rather easily upset the balance of the machine and may cause serious operating conditions. The construction of the armature is more complicated than either a direct-current armature or an alternating-current motor rotor or exciting field. The additional connections to the winding of the converter armature are both difficult to bring out and usually far from easy to repair. No matter in which direction the ventilation of the converter armature is designed carbon or metallic dust is sure to get into the winding, where it easily lodges and is not readily removed. Owing to this condition, blowing air into either end of the winding probably will more tightly lodge dust and dirt into one end or the other.

Greater care in starting a converter also is important. Depending upon the type, it usually is necessary either to raise the brushes or break up the field in starting. Then, again, the converter may build up in the wrong direction, thus requiring a re-start or a shift of a pole. The double-throw knife-blade switch used for starting the converter and putting it on full voltage always has been a source of danger both in starting and when running. Furthermore, occasions have been known where this switch has been accidentally opened under load in an attempt to take the converter off the line. In such cases the result was especially dangerous to the operator and equipment.

All these difficulties either do not exist with starting a synchronous motor or are far less dangerous. The starting switch of the synchronous motor invariably is an oil switch and can easily be arranged so that the operator need not come anywhere near any live parts.

Another point of advantage that the synchronous motor-generator set has is the fact that it is, as the name implies, a motor and a generator. Both these machines are popular all through the mining properties and therefore are pretty well understood by almost every electrician and electrician's helper. For this reason they will attack a breakdown job on the motor-generator set with far more confidence than they would have in attempting to repair a synchronous converter. This feeling is also borne out all through the life of the

A TYPICAL MOTOR-GENERATOR SET
This machine has become very popular in the coal field, as it readily lends itself to either manual or automatic operation and control. It may be easily knocked down for transportation through the mines to remote places.

AN INSIDE SUBSTATION OF INTEREST

These motor-generator sets were so designed as to be readily accessible in case of breakdown. This is important where equipment has been installed at a point in the mines far distant from the repair shop. The control of this station is not automatic as it is in some of the more recent installations.

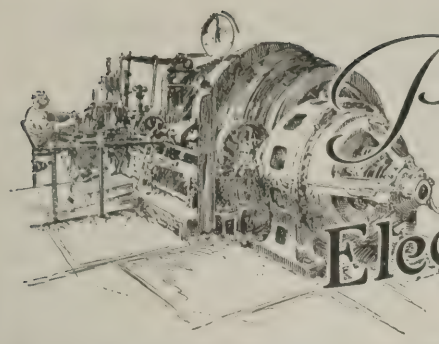
machine, as it is quite noticeable that synchronous converter substations are more frequently shunned on inspection trips and whenever tests are to be made to determine the condition of equipment.

Two of the most important factors which determine the location of converting equipment at a coal mine are center of the load and accessibility. Frequently these factors demand that the converting equipment be in places where it is inconvenient to locate step-down transformers for a synchronous converter and also entailing expense, danger and inconvenience in case of a breakdown. Here the synchronous motor-generator set seems to fit in well. The high-tension voltage for the motor in most cases may be taken direct from the supply lines without the use of transformers and even where transformers are required it seldom matters a great deal where they are placed with respect to the location of the motor-generator set. They may even be of sufficient size and be so located as to carry other loads whenever they are required.

When located inside the mine or in a place not readily accessible the synchronous motor-generator set may be housed in a small space and presents less difficulty in setting up than the synchronous converter with its transformers. Where an automatic substation is to be set up it has appeared that the starting and stopping could more readily be controlled from a remote place when a synchronous motor-generator set rather than when a synchronous converter is used, this being particularly true where the machine is installed inside the mine and the control equipment is for the most part outside the mine in a separate control house.

The load on the converting equipment of a coal mine usually consists, in the main, of haulage machines—generally locomotives and hoist. The very nature of the work of these machines makes the load on the converting equipment very irregular. At times these irregularities become extremely severe and sudden, as, for instance, when an attempt is made to start a very heavy trip or to replace a trip of cars on the track after a derailment. On this kind of irregular load the synchronous converter sometimes gives trouble by flashing and burning the commutator and brush rigging. The machine is liable to hunt and become dangerous. The difficulties which arise, if at all, with a synchronous motor-generator set under these same conditions are far less pronounced.

A greater appreciation of the advantages of the induction motor in coal mining, due to its rugged construction and lack of the troublesome commutator will gradually become more generally realized. With this greater appreciation of the induction motor will come the realization of the flexibility of alternating current and the advantages of higher voltages for transmission and distribution systems.



The increased application of the induction motor necessarily brings about a condition whereby the large inductive loads produce a lagging power factor which may become important if the induction motors are applied to a large percentage of varying loads or to loads that are highly overmotored. The excessive lagging current thus produced may become very troublesome, necessitating larger distribution wires, larger transformers and larger generators. Fortunately, this condition of lagging power factor due to the high inductive load produced by the induction motors can be corrected at the coal mine.

Here the synchronous motor-generator set again has a definite advantage over the synchronous converter. The synchronous converter can help the situation to some degree but cannot be called upon to materially correct poor power factor, while the synchronous motor may be called upon to partly correct the poor power factor of the system. With a slightly increased capacity in the synchronous motor over that required for the direct-current load, considerable correction can be made with little difficulty, thus bringing the power factor to a very reasonable operating value.

Consumer to Blame for High Power Bills

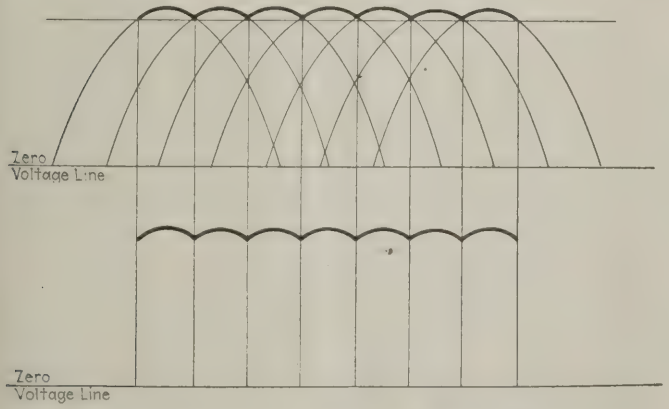
Many of the complaints against the power companies by purchasers of power are unjustifiable, because in a great measure they are due to some condition arising from the fact that the consumer has not used good judgment in the selection of his equipment. Many of the grievances complained of could be best remedied not by the power company but by the consumer himself, as most of them are in some way connected with poor power factor. They may be in the form of a complaint about low voltage, poor voltage regulation, fuses opening the lines frequently, circuit-breakers tripping, overheated motors, high magnetizing current in equipment, low torque from motors, high equipment costs, high kva. capacities required throughout the system. After all, the installation of a synchronous motor generator set is one of the best remedies for these difficulties.

With greater demands upon the central stations for more power it is natural to find a continual revision of power schedules by the power companies. The greatest changes in these schedules, although not always immediately enforced, are with reference to penalties for low power-factor loads. Some of these penalties are no doubt unjustifiable, in some cases, because they charge the consumer for out-of-phase kva. at the same rate as for true power, yet properly arranged penalties for poor power factor are justifiable. The conditions which the consumer is apt to complain about are based upon facts which he himself would have to meet if he were making his own power; therefore it behooves the consumer to operate his equipment to the best advantage lest he be penalized for conditions which would handicap his own generating plant if he were making his own power.

Practical Pointers for Electrical and Mechanical Men

Function of and Operation of the Series Field of a Rotary Converter

WILL you be kind enough to explain in your columns the function of the series field on a rotary converter? I understand that on a compound generator the increased load acts to raise the voltage by the increased field established by the series field current. From what I have read about rotary converters this does not seem to be the same case, although the winding is called the same, is located the same and carries the load current in the same manner.



J. R.

It is true that the series field winding on a rotary converter is located the same as on a compound generator. With certain modifications it also does the same work as the series field of a compound generator. However, to best understand the rotary converter we must first of all remember that the ratio between the alternating-current voltage and the direct-current voltage is fixed. The rotary converter in its simplest terms is a machine which takes a given alternating current voltage and picks off the tops of the rapid succession of alternating-current waves and ties them all together and forms a direct-current voltage—in other words, the rotary converter is a commutating machine. In this way we see that if we start off with a low alternating-current voltage this means that the potential of the peaks of these waves is low and when these low peaks are picked off and combined to form a direct-current voltage, then the resulting direct-current voltage must be low.

When the load comes on the direct-current end of a rotary converter this same load, of course, is transmitted back to the alternating-current end and upon the alternating-current supply. When this happens certain conditions arise in the alternating-current system which reduced the alternating-current voltage. Consequently, since there is a definite ratio between the alternating-current voltage and the direct-current voltage, the direct-current voltage from the rotary drops with the alternating-current voltage.

The series field, however, functions under these conditions and causes an effect in the alternating-current system to neutralize the cause of the drop in alternating-current voltage. By thus maintaining the alternating-current voltage the series field indirectly maintains the direct-current voltage. In some cases it may even raise the direct-current voltage, but whatever it may be, in this event, it cannot be a great deal.

Questions calling for special treatment constantly come to electrical and mechanical men at coal mines. These cover equipment and materials for special needs. Every time you find a solution for one of your problems, send it to "Coal Age" and thus pass it along to others. Send your questions in too.

CONVERTING ALTERNATING TO DIRECT CURRENT

The upper section shows the upper halves of a series of alternating-current waves. The heavy section shows the part commutated. The lower section represents the resulting direct-current voltage. Note that the closer the alternating-current waves the less pronounced become the ripples in the direct-current voltage.

The Delta Connection Made Clear

METHODS of connections used with alternating current are sometimes confusing. Many times the connection cannot be definitely ascertained until a close inspection has been made. In three-phase work the general plans of connecting equipment resolve into three general types. One of the most common connections is termed the "delta."

As with all equipment used on electrical circuits it is important to make every connection and each part of a general connection correctly. Strange as it may seem, I have known some very good electricians and electrical helpers who lacked a very clear conception of the delta connection; in fact, some of these men could correctly connect up a bank of transformers in delta and yet were completely lost in connecting three coils, say, on a tripping device, in delta.

The important point to bear in mind when making a delta connection is that each coil involved in the delta connection should be suitable in voltage rating for connection directly across the voltage of the line. For example, a transformer winding or motor winding to be connected in delta with two other similar windings should have the same voltage rating as that measured across any two wires of the line. From this

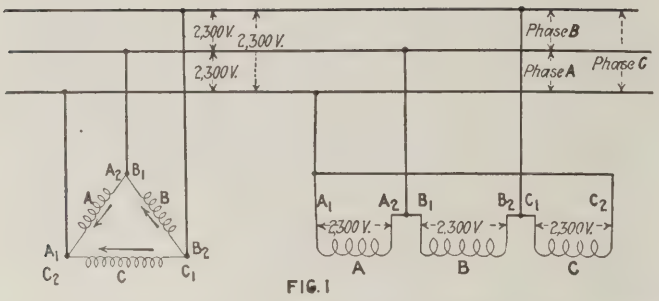


FIG. 1—COIL ARRANGEMENT IN THE DELTA

Each of the three coils is across a phase of the three-phase system and therefore must have the same nominal voltage rating as the line voltage.

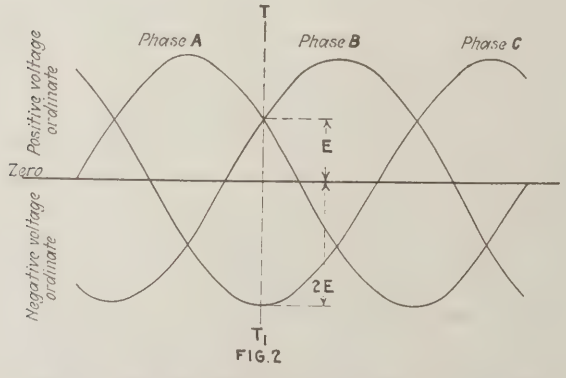
we see clearly that the 2,300-volt winding of a transformer may be connected in delta with two other similar transformers to a three-phase 2,300-volt alternating-current line.

The accompanying diagram shows both a schematic delta connection and the usual arrangement of the delta connection applying to transformers or any other group of coils having the same voltage rating as the line—for example, the coils of an induction motor.

In Fig. 1 the arrangement appears as if the different windings were short-circuited, but this is not the case, as the phase differences or times of impulses of the various three-phase voltages prevent such a thing when the connections are properly made. When the voltages on any two coils or windings are in the same direction around the triangle formed by the delta connection, the voltage of the third one is always opposed to them and equal to the instantaneous sum of the two.

This is rendered quite obvious by Fig. 2. At a given instant of time called TT_1, both phase A and B are positive in the amount represented by the distance E. These two values of voltage, since they are in the same direction, may be directly added together and give a total amounting to $2E$.

Again looking at Fig. 2 we notice that at this same instant phase C is working in the opposite direction, represented by a value $2E$, which balances the sum of the voltages of phases A and B. In Fig. 1 the voltage arrows again bring out this point. It will be noticed that the arrow at coil C is twice that at coils A and B and opposite in direction, thus maintaining the balance. In this way the balance always is maintained between the values of the voltages at any one instant.



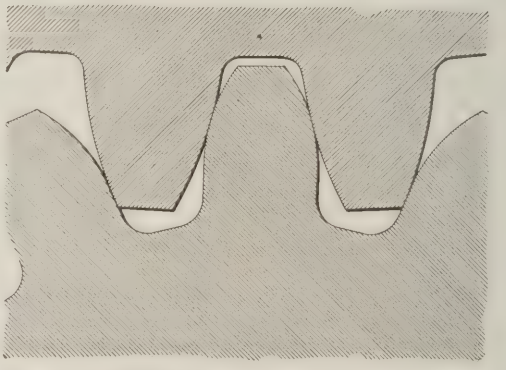


FIG. 2—PHASE VOLTAGES ALWAYS BALANCE

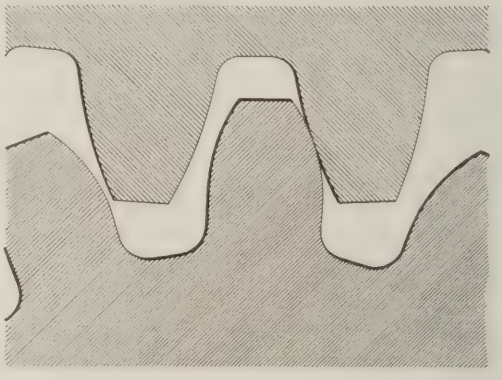
Drawing a line parallel to TT_1 will show that at any instant the voltages balance. Care should be taken to consider both the direction and value of all the instantaneous voltages. At the instant shown voltage of phase A is positive E, phase B is positive E and phase C is negative 2E which balances E + E of phases A and B.

What Is the Maximum Permissible Wear Of Locomotive Motor Bearings?



A SERIOUS evil frequently allowed to exist on mine locomotives is excessive wear of the armature and back-axle linings. This is one of the causes that tend most to shorten the life of gears and pinions as well as to cause expensive delays. If maximum life is expected from gears and pinions the maximum wear limits of the armature and back-axle linings should be set at a predetermined limit.

For 3- and 2½-pitch gears it is good practice to set the maximum limits at $\frac{1}{16}$ in. for the armature lining

PROPERLY MESHED GEAR AND PINION

This insures smooth, easy and quiet running; no breaking of teeth and no pounding out of bearings.

GEAR AND PINION IMPROPERLY MESHED

This shows the condition when the shaft centers are $\frac{1}{16}$ in. too great. Note that the top of the tooth is doing the work and the large back lash.

and $\frac{1}{8}$ in. for the back-axle lining; for smaller teeth these limits should be reduced.

In the accompanying illustrations, which show the exact size of a popular new 3-pitch gear and pinion in mesh, one shows the correct mesh when the armature and back-axle linings are in perfect condition, while the other depicts actual conditions with the same new gear and pinion when the armature lining is worn $\frac{1}{16}$ in. and the axle lining $\frac{1}{8}$ in. Note the improper mesh and extreme back lash. This causes noise, broken teeth and a surprising reduction in life.

For checking the wear of the linings a tapered gage can readily be made. If the axle is enclosed in a dust guard which is not provided with an inspection door, by jacking up the bearing housing with a block and pinch bar, a fair estimate of the axle lining wear can be made without removing the guard.

New gears are expensive, especially when the cost of taking the old gear off and putting the new gear on is allowed for.

Book Reviews

Carbon-Dioxide and Methane Outbursts in Coal Region of the Gard, France

By F. C. Cornet

APPOINTED in 1913 by the Southeastern Branch of the "Société de l'Industrie Minérale (Mineral Industry Society), of France, to investigate and report on the outbursts of methane and carbon dioxide occurring so frequently in the mines of the Gard coal field, in central France, the Commission des dégagements instantanés (Gas outbursts commission) has just made its report in a paper-covered volume of 40 pages 8¼ x 10⅝ in.

The Gard coal field is small, its area being less than 200 square miles, but no more disturbed area could well be imagined, the seams pitching at all possible angles and in all directions of the compass. These geological conditions are worst in the southeastern half of the field, where practically all the outbursts have been of carbon dioxide. In the northwestern section of the field, where methane outbursts happen quite frequently, carbon dioxide seldom is found in any troublesome quantity.

Though the seams mined in the northwest are obviously not the same as those mined in the southeast, it is still a question which group of seams is the lower geologically. The first outburst, one of methane, occurred in the northwest area in 1879. Since then, if the field be considered as a whole, more than 1,600 blowouts have been recorded, 1,100 of which are of carbon dioxide. Only a few of the outbursts have discharged a mixture of that gas with methane.

Most Violent Gas Is the Carbon Dioxide

The most violent, by far of the outbursts always have been those of carbon dioxide. Some of the latter have occurred under a cover as light as 400 ft., and, it may be added, no mine in the field is more than 1,000 ft. below the surface. In not a single instance has the opening created by a blowout been large enough to account for more than a fraction of the fine coal and slate thrown out by the manifestation.

Boreholes as advance detectors of danger have proved as illusory as they do in every other place where blowouts occur. Methane blowouts happen only in soft and easily mined seams—that is, in coals which have sustained in past geologic ages such crushing as to deprive them of their cohesion. Blowouts of carbon dioxide generally occur in hard seams the appearance of which little indicates the terrific upheavals to which they have been subjected in the past.

All outbursts, both of carbon dioxide and methane, are preceded by underground thunder, crushing of timbers, wind blasts and dust clouds. The notice of danger thus given may be of a few seconds only, but the premonitory signs sometimes will last hours and have been known to continue intermittently through several days. The longer the warning, the less violent the outburst.

It often has been remarked that shortly before a blowout of carbon dioxide occurs the face becomes appreciably colder than the atmosphere of the workings, especially if the seam be damp. Some of the worst blowouts happen when a seam is reached by a *bouveau*, which the French call a *travers-banc*, or by a shaft or is on the point of being reached by either one.

In a preceding article* has been described the method by which the Gard operators provoke blowouts by so-called "jarring blasts." This method is adopted in shaft sinking, in *travers-banc* driving and in regular mining work. When pillars of comparatively small area have been left standing for a sufficiently long time, however, they sometimes may be recovered without resorting to the jarring blast.

In the case of carbon dioxide a pillar is a long time being purged of its gas. A methane blowout will free the coal of its gaseous contents for some distance ahead, and the seam in consequence, must be penetrated a little further before another such blowout will occur. But one blowout of carbon dioxide, on the other hand, may follow immediately after another—that is, two consecutive jarring blasts may each cause a blowout at the same face.

The commission's report devotes several pages to the rules followed or recommended in connection with jarring blasts. It is urged that all such blasts be fired from the outside exclusively. On account of its high specific gravity, the carbon dioxide after a blowout will fill the mine down to its lowest levels unless prevented from so doing by a strong and voluminous air current. In many instances the gas has reached the surface through both the downcast and the upcast at the same time. It has been known thus to asphyxiate the men working at the top of the hoisting shaft.

In at least one instance, at night, a carbon-dioxide outburst carried up the hoisting shaft a quantity of fine coal and dirt sufficiently large to block a public road, the gas spreading at the same time into houses situated more than a thousand feet away and asphyxiating men, women and children in their beds, some on the second floor of the houses they occupied. The report says nothing concerning the probable causes of either the carbon-dioxide or the methane blowouts.

*"Precautions to Guard Men from Seam Outbursts," *Coal Age*, March 8, 1923, pp. 408-411.

Desulphurization of Coke by Steam

IN THE course of laboratory experiments in the desulphurization of coke by steam being conducted by the Department of the Interior at the Pittsburgh experiment station of the Bureau of Mines, steam tests at atmospheric pressure for the removal of sulphur from lump coke have been finished. In Ohio the combined sulphur as FeS, $FeSO_4$ and free sulphur (not including that in solid solution) was reduced from 1.38 to 0.72 per cent. The solid-solution sulphur was not affected, but it has been shown that this has little effect in contaminating the sponge iron in the blast furnace. In Illinois coke 0.62 per cent sulphur correspondingly was reduced to 0.48. Clairton coke, which is low in sulphur, was reduced from 0.29 to 0.17 per cent. Sulphur in a sample of gas-house coke from Philadelphia was reduced from 0.81 per cent to 0.60. These results were obtained without the application of a vacuum, in the presence of which it may be possible still further to reduce the percentage of sulphur. Little steam is required.

Problems of Operating Men

Edited by James T. Beard

Blame for Explosions in Mines

Analyzing the Situation—The Company, the Superintendent, the Mine Manager—Chief Fault in the Employment of Incapable Men

FOR some time past, it has been a common thing, on picking up a newspaper, to read the account of another mine disaster with the loss of a hundred or more lives. The question naturally comes home to all of us as to where the blame for these dread occurrences should rest.

To reach a more intelligent conclusion in answer to this question, let us analyze the situation in respect to the men who are personally responsible for the management of our mines. These men, in the order of their responsibility, are the mine owners or management, the superintendent employed by the company and the mine manager (mine foreman).

Now, I know of no mine owners or of any management of mines who are indifferent to the possible occurrence of a disaster in one of their mines. If for no other reason than the great loss of life involved they naturally do all in their power to avoid such an occurrence in their mines.

In all my experience in coal mining, I have observed an almost lavish expenditure of money to provide the necessary machinery and other appliances for the adequate ventilation of the mines and making them safe for work. It is foolish to think that these expenditures would be withheld where money is needed for the safe operation of a mine.

It is not in this respect that companies commonly fail in their responsibility for safety. On the other hand, however, it frequently happens that a company will employ a superintendent who is not a practical man in respect to knowing what is needed underground to properly safeguard the work. The employment of such a man as superintendent will always prove a handicap to a practical mine manager (foreman).

Must Obey Orders of His Superintendent

In the operation of a mine, the mine manager is naturally subject to the orders of the mine superintendent who holds the higher office. For this reason, it is all the more important that the man who occupies the position of mine superintendent should have a practical as well as a theoretical knowledge of the mining of coal, and be fully acquainted with the conditions existing in the mine, through his own personal experience underground.

Turning now to the mine manager or foreman, who is in direct charge of the work performed in the mine, any lack of practical knowledge and experience on his part or failure to properly perform his duties may cost him his own life and sacrifice the lives of the men in his charge, as was the case in the last two explosions, at Dawson, New Mexico, where all in the mine were killed in each explosion.

To the practical miner, these happenings are not mysterious. It is hard to make him believe that a single unauthorized shot was the cause of the explosion in a mine classed as a non-gaseous mine. His invariable conclusion would be that gas had accumulated at some point in the old workings, or in some poorly ventilated place that had been driven ahead of the air and stopped.

The practical miner is prone to believe that some fellow, ignorant of his danger, walked into such a place with an open light on his head, or smoking a pipe, and set off the gas that has escaped the notice of the fireboss when making his morning examination of the mine.

In such an instance, the responsibility for the disaster is attributed to the failure of the mine examiner (fireboss) to properly perform his duties in the mine. It is true that, in many cases, it can be shown the territory was too large to permit of a careful examination, within the time allotted for that purpose, and the real responsibility for such a condition is then thrown back on the management or owners of the mine.

Allow me, in closing, to state my opinion that the chief fault, in respect to mine disasters, lies in the employment of incapable men to take charge of the work, rather than any lack of expenditure in making the mine safe. Mine disasters will continue until capable men are placed in charge of the work.

Edwardsville, Ill. DAVID YOUNG.

Clearance on Haulways

Crooked roads driven without sights cause many accidents—Capable foremen insist on all entries and rooms being driven on sights—The foreman on the job.

HAVING missed my *Coal Age*, for a short time past, it was with deep interest that I recently read numerous letters relating to mine accidents and their causes. One writer asks, "What causes so many accidents in the coal mines?"

Every person, of course, has their own way of thinking and each is guided by his own particular experience in accounting for the great number of accidents, both fatal and non-fatal. In a few words, I want to draw attention to one frequent cause of accident, for which there is little or no excuse, if the mine foreman in charge is capable and efficient.

Going into different mines, it is a common thing to observe crooked roads. Naturally, the tracklayer has not kept the track in the center of the entry; but it first brushes one rib and then the other as the entry bends from side to side. With due care on the part of the foreman in charge of the work, all of this could have been avoided.

In my experience, a large number of accidents are due to these crooked roads. There is no wide side

having a good clearance where men can walk with safety. Drivers are in constant danger of being caught between the car and the rib, at points where the track hugs one side of the entry. In many cases, the cars actually rub a post, which is in danger of being knocked out at any time.

Strange as it may seem, hardly one man in ten can keep an entry straight, even when good sights are given. Many certified foremen and assistant foremen fail in this respect. All will agree, however, that safety requires maintaining a good wide clearance continuously on one side of the entry; but this cannot be done unless the road is practically straight.

Every capable mine foreman will insist on sights being given in the driving of all rooms and entries. A foreman who is a foreman in action as well as in name, is the man who is on the job throughout the day. He does not wait for the mine inspector to tell him he must get busy and straighten his roads, slabbing the ribs at points where that is required to give the necessary clearance. Instead, the inspector finds the roads are straight and there is no cause for complaint.

The foreman who is on the job is not the man to depend on his assistants alone. He is there to see for himself. You will not find him sitting in his office when the mine is in operation; and the result of his constant watchfulness and supervision of the work is shown in the daily cost-sheet. He is not the man whom the superintendent must watch nor has he any fear of interference from that source.

Let me say, then, if accidents are to be avoided, the foreman must be on the job, work in harmony with the inspector and feel the responsibility resting on him for the safe operation of the mine, in every detail pertaining thereto.

It is a sad mistake for a mine foreman to think that, having secured his papers, he is in a position to lay down on his job. He should realize that now is the time to show what he is worth as acts go farther than words. Getting his papers does not relieve the man from continued study and reading to keep himself up to date.

JOHN H. WILEY.

Oliphant Furnace, Pa.

Economic Aspect of Mine Disasters

Foreman vainly appeals to superintendent to make mine safer—Accidents increase cost of production—Effect of compensation insurance—Mining of large coal a factor.

READING the excellent editorial entitled "Fundamentally Wrong," *Coal Age*, March 8, p. 398, found me very much in harmony with most of the assertions relating to practices, in our mines, that have a tendency to increase rather than decrease mine accidents. The editorial closes by saying, "Something will and must be done to make our mines safer."

The expression "our mines" led me to feel that the writer of the editorial, like myself, felt and was willing to assume his share of responsibility in the prevention of mine accidents. It awakened in my heart a friendly feeling, as it showed no discrimination; but recognized the obligation that rests on all of us alike to do our part, as far as lies in our power, to eliminate the numerous causes of accidents and make our mines safer.

Recently, some conditions existing in our mines, here, prompted me to request my employer to do something to lessen the hazard to life and limb. In response, I got no satisfaction and was probably thought to be radical in my ideas of safety. However that may be, I only acted according to the dictates of my conscience and in behalf of myself and others. I was speaking both from a humane and an economic standpoint.

Could our mine officials but visit the hospitals, say once each month, what they would see there might convince them that 90 per cent of the suffering and distress resulted from what can be called "avoidable accidents." The sight, I believe, would stimulate them to action for the prevention of accidents, and both they and we would be benefited.

Many operators lose sight of the fact that accidents in their mines are a liability to be covered by the operation of the mine. As we all know, however, the operator passes the burden on to the consumer, who is the ultimate sufferer and must stand the increased cost of production, which is sure to follow. The question is thus seen to be an economic one that should interest the public, at least in their own behalf aside from humane reasons.

The statement may surprise some that a number of our best mines, as far as natural conditions are concerned, make the worse showing in respect to the number of fatal and non-fatal accidents. The reason for this is to be found largely in the effect of the operation of the Compensation Law and the assumption of accident risks by the affiliated insurance companies.

Too Little Supervision of Workers in Mines

My observation leads me to suspect that, in certain cases, companies are paying less attention to the supervision of their mines, allowing the payment of liability insurance to take the place, in a measure, and render unnecessary the employment of safety inspectors. Without a doubt, this has been the direct cause of some accidents. In my opinion, while fire insurance is a great help in most cases, if there were no means of such insurance, there would be a less number of fires.

In my own mind, while admitting that workmen's compensation, as provided by law in many states, is a great benefit to the unfortunate victim of accident, the question has often arisen as to whether the law has had the tendency to reduce the number of accidents that occur in our mines, as was hoped would be the case.

The editorial writer has mentioned the practice of "topping," in the loading of mine cars, as an argument against rock dusting, which he says has not been followed extensively in this country. It must be admitted, however, there is no question but that the practice of topping mine cars has had a tendency to produce large coal in mining, which greatly lessens the dust danger in the mine.

Another incentive to the mining of large coal was lost in the adoption of the mine-run basis of payment. Previously, when lump coal was made the basis of payment, great care was taken by the miners to avoid the production of fine coal and slack, which would go through the screens and afford the miner no return. With the loss of this incentive to mine large coal, are we now to look for doing away with the practice of topping the cars in loading?

Doubtless, the topping practice has some tendency to increase the dust danger, by reason of much coal being lost in transit from the working face to the shaft bottom or the tipple. However, it seems as though there

should be another remedy to overcome that evil. In all of these matters, let us hope that good reasoning will save us, who mine the coal and the public who consume it and, incidentally, reduce the high cost of production and the number of mine accidents.

Linton, Ind. W. H. LUXTON.

Difficult Examination Question

Circulation in a shaft mine increased by adding another airway—Solution first assumes constant quantity and then constant power.

SOME time ago, I recall that the solution of a difficult examination question was asked and answered in *Coal Age* [Vol. 22, p. 1002]. Later, in the issue of March 1, p. 379, a contributor offered a solution of the same question by the equivalent-orifice method. Both of these solutions seemed to me difficult and I want to offer the following:

Briefly stated, the question assumed a circulation of 10,000 cu.ft. of air per min., in a mine ventilated by two shafts, each 6x6 ft., in section, and 500 ft. deep. The air was passing in a single current through an airway having the same section as the shafts and 1,000 ft. long, making the resistance of the airway equal to that of the two shafts combined. The question asked, How much this circulation would be increased by adding another airway of the same size as the first, the power remaining unchanged?

The solution I would suggest is the following: First, assume the quantity of air in circulation to be constant and find the relative power required in the two cases. For example, writing the formula for power (H), in terms of the rubbing surface (s) and the sectional area of the shafts or airway (a), for a given quantity of air in circulation (q), and a coefficient of friction (k),

$$H = \frac{ksq^3}{a^3}$$

But, k and q being constant, it is evident the power varies as s/a^3. Now, since the sectional area of each shaft and that of the airway is the same throughout the length of the airway is equal to the combined depths of the two shafts, it is clear that the addition of a second airway will double both the sectional area and the rubbing surface in the mine. Then, taking the area and rubbing surface of the shafts or single airway as unity or 1, since the power varies as s/a^3, we can write for the power absorbed in the shafts and airways, in each respective case as follows:

1st case,

shafts $1/1^3 = 1$; airway $1/1^3 = 1$; total 2 hp.

2nd case,

shafts $1/1^3 = 1$; airways $2/2^3 = \frac{1}{4}$; total $1\frac{1}{4}$ hp.

This shows that to pass a constant quantity of air in these two cases, the power is reduced from 2 hp. in the first case, to $1\frac{1}{4}$ hp. in the second case, or as 8:5.

Then, finally, since the quantity varies as the cube root of the power in a given airway, and calling x the required quantity in circulation in the second case when the power is increased from $1\frac{1}{4}$ to 2, or in the ratio 5:8, we have,

$$\frac{x}{10{,}000} = \sqrt[3]{\frac{8}{5}} = \sqrt[3]{1.6} = 1.1696$$

$$x = 10{,}000 \times 1.1696 = 11{,}696 \text{ cu.ft. per min.}$$

I submit this as being the simplest possible solution of such a problem. MAC.

River Herbert West, N. S.

Inquiries Of General Interest

Depth of Coal Mines in Belgium Often Exceeds 1,000 Meters

Dispute Regarding Depth of Mining Coal in Belgium—Question Referred to Expert Shows Shaft Exceeding 4,000 Ft. in Depth

RECENTLY, I had quite an argument with a mine boss in this locality regarding the depth of Belgian mines. I was speaking of the great depth of some of the coal shafts in the basin of Charleroi, in the Province of Hainaut, Belgium, where I was born.

In the conversation, I referred to one mine in particular that went by the name of "Parrent." While unable to give the exact depth of the shaft, I explained that it was very deep and had a curve, the result of being thrown out of line by changes that had taken place in the strata since the shaft was sunk.

My friend told me that no mine in Belgium lay at a depth of 1,000 yd., which I had said was exceeded in the shaft mentioned. As I have been unable to meet his challenge to prove the correctness of my assertion that there were a number of mines in Belgium having a depth greater than 1,000 yd., I decided to write to *Coal Age*, asking for corroboration of my statement.

My friend is one who is hard to convince. He is the type of man who "knows it all," and should he see the proof of my claim published in the columns of *Coal Age*, it would still be difficult for him to acknowledge that he was wrong. CHARLES TROYE.

West Terre Haute, Ind.

The question of this correspondent was referred to F. C. Cornet, a mining engineer who is thoroughly familiar with the mining of coal in Belgium, and who recently contributed an interesting article on Blowouts in Belgium Coal Seams, which appeared in *Coal Age*, March 1, p. 367. In response to our request, Mr. Cornet writes as follows:

A depth of 1,000 yd. (3,000 ft.) places a shaft in the 900-1,000-meter class, of which there are probably fifty or sixty examples in Belgium. When speaking of their mines, Belgians seldom specify the depth of the shaft, except where this exceeds 1,000 meters (3,280 ft.). For this reason, it is hard to state the exact number of shafts in Belgium belonging to the class mentioned.

Last year, there were seventeen mines whose depths varied from 1,000 to 1,100 meters (3,280-3,609 ft.). There were two mines having depths varying from 1,100 to 1,200 meters (3,609-3,937 ft.). There was one mine whose depth was 1,240 meters (4,068 ft.). To this depth must be added a 40-ft. sump to obtain the depth of sinking.

These figures show that there were twenty mines in Belgium last year worked at a depth exceeding 1,000 meters. Since the mining laws permit no mine to be operated with less than two shafts, we can certainly say there were at least forty shafts whose depths exceeded 1,000 meters.

Examination Questions Answered

Alabama Foremen's Examination, Birmingham, Jan. 22, 1923

(Selected 2nd Class Questions)

QUESTION—*A large percentage of mine accidents are caused by miners persisting in loading coal where the roof is unsafe. What rule would you adopt to prevent this condition and reduce the number of accidents?*

ANSWER—A rule strictly forbidding the loading of coal or doing other work when a miner enters his place in the morning, until he has carefully examined the roof in his place and has set any timbers that may have been dislodged by the shots of the night before, or that may be needed to make the place safe for work. This rule should be strictly enforced and any violation suitably punished.

QUESTION—*What method of ventilation lessens the danger of an explosion and at the same time reduces friction?*

ANSWER—The method known as "splitting the air current," or dividing it into two or more splits, makes it possible to distribute the air according to the need in each section of the mine. The mine is thus divided into separate ventilation districts and a local explosion occurring in one district is not so readily transmitted to another district, thus rendering the mine less liable to a general mine explosion. Again, the velocity of the air is reduced, making it less liable to transport dust and hold it in suspension in the air, which also reduces the liability to an explosion. Moreover, the reduced velocity of the air current creates less friction, as the friction of air varies with the square of the velocity of the current.

QUESTION—*Accidents from blasts and explosions of powder are on the increase. What should be done to reduce them? Answer fully.*

ANSWER—Where black powder is in use, all holes for blasting should be carefully examined before a miner is permitted to charge and fire a hole. The use of black powder should not be permitted in mines generating gas or dust and strict regulations should be made and enforced, limiting the amount of charge to be used in a single hole and the number of shots to be fired at one time, in a single place. Preferably, all shots should be examined, charged and fired by competent shotfirers after the men have left the mine. In mines generating gas and dust in dangerous quantity, only permissible powder should be employed and all shots should be charged and fired by competent shotfirers employed for that purpose.

QUESTION—*If the ventilation of a mine is insufficient, how may it be increased without increasing the power?*

ANSWER—To increase the circulation in a mine without increasing the power on the air, it is necessary to divide the current into two or more splits, so as to reduce the velocity of the passing air and the friction. Also, every obstruction to the free passage of the current should be removed and all breakthroughs and crosscuts enlarged to the full section of the airway. As far as practicable, the length of air travel should be shortened and sharp bends in the air-courses avoided.

QUESTION—*Are there any precautions you could adopt to insure greater safety to the workmen in the mine, other than what is required by law?*

ANSWER—Greater safety in any mine is insured at the expense of constant, close, supervision of the work, not only to see that the mine is operated in compliance with the requirements of the law, but that all unsafe practices are eliminated and that everything is done to meet the special conditions that exist in that particular mine. For example, the practice of solid shooting, while safe in the mining of anthracite and other hard coal, if properly performed, is very unsafe in the mining of a soft friable coal and when performed by an inexperienced miner. Where the conditions require, which is the case in many mines, all shots should be examined, charged and fired by competent shotfirers employed for that purpose, and the work should be done after the men have left the mine.

Greater safety is assured by the use of permissible powders in place of black powder. Where men are hauled in and out of the mine on a special trip as provided by law, safety requires that no explosives or tools be carried by the men in that trip; but these should be sent into the mine on a separate trip. By a careful study of the conditions in his particular mine, every foreman will find the need of special precautions being taken to secure greater safety than what is mentioned in the law.

QUESTION—*What are the requirements of the law in Alabama in regard to handling and storing explosives in the mine? Where should they be kept and in what quantities?*

ANSWER—Regarding the handling of explosives in mine, Sec. 3 of the Alabama law requires a man's lamp to be placed 5 ft. away in the direction in which the air is moving; nor shall any person approach nearer than 10 ft. to an open can of powder, having a lighted lamp or pipe, or other fire with him. The same section forbids the opening of a can of powder with a pick or other tool.

In regard to storage of explosives in the mine, the law (Sec. 84) requires such explosives to be kept in a locked wooden box, placed as far as practicable from other boxes and from the track, and not nearer than 100 ft. to any working place. Black powder or other loose material for blasting must be carried into the mine, by the miner, in a proper receptacle having a securely fastened top. The law (Sec. 85) forbids blasting powder or other explosives being stored in the mine and no workman is permitted to have in his place, at one time, an amount greater than what is specified by the rules and regulations of the mine. More than one kind of explosive must not be placed in the same hole. The law forbids (Sec. 86) a person having in his possession any explosives other than that permitted by the rules of the mine, and permits (Sec. 88) the use of dynamite in the mine, only by the written consent of the foreman or other person in charge, stating the use intended.

QUESTION—*How many cubic feet of air passes along an airway 6 ft. high and 10 ft. wide, the velocity being 450 ft. per min.?*

ANSWER—The sectional area of this airway is $6 \times 10 = 60$ sq.ft. Then, for an average velocity of 450 ft. per min., the quantity of air passing is $60 \times 450 = 27{,}000$ cu.ft. per min.

Labor and Its Handling Make "Astounding" Progress in Efficiency

A report on the efficiency of labor and efficiency in handling labor will be issued soon by the Department of Commerce, Secretary Hoover having caused a special study of these related subjects to be made for some months.

The report, it is said, will show that "astounding" progress has been made in the United States in the last ten years. Labor turnover has been reduced materially by improvement of management, the report will show, while the efficiency of labor also has improved.

In view of the attitude of the administration against material relaxation of the immigration laws, the forthcoming report is considered of especial importance.

In the opinion of Secretary Hoover, industry must look to increased efficiency, not only of labor but in handling labor, to solve its labor problems, rather than to an influx of foreign workers.

M-O-I Coal Convention Program Maturing

The program for the annual convention of the Michigan-Ohio-Indiana Coal Association, to be held in Cincinnati, May 22 to 24, is rapidly taking shape according to an announcement by B. F. Nigh, of Columbus, secretary of the association. Plans for entertainment as well as the business program provide for three full days and the biggest meeting in the history of the association is expected.

The business program has not been completed, but one of the leading speakers will be Tom L. Lewis, advisor to the New River Coal Operators' Association, on "What Is the Matter with the Coal Industry?" J. D. A. Morrow, of the Morrow Callahan Coal Co., also will speak, as will J. A. Morris, chairman of the operating committee of the American Railway Association, whose subject will be "The Railroad Outlook." Headquarters will be at the Sinton Hotel.

Automobiles will be provided for all visiting ladies both for shopping and sightseeing. The entertainment program for the members will include a barbecue and other features. Nothing will be left undone to make the meeting a success.

Coal-Mine Fatalities Drop in March

Fatal accidents to employees at coal mines throughout the United States during March, 1923, according to reports received by the U. S. Bureau of Mines from state mine inspectors, numbered 168, as compared with 296 in February, 1923, and 196 in March, 1922. The fatality rate was 2.99 per million tons, based upon a production of 56,205,000 tons in March, as against a rate of 5.93 for February of the present year and 3.34 for March a year ago.

During the first three months of 1923 661 fatalities have occurred at coal mines, representing a fatality rate of 4.01 per million tons based upon an output of 164,999,000 tons of coal. In the corresponding three months last year the fatality rate per million tons was 3.95, the fatalities numbering 593 and the production of coal being 150,098,000 tons. The fatal-accident rate for March during the ten years 1913-1922 has averaged 4.06 per million tons.

An explosion of coal dust on March 2 at a mine at Arista, W. Va., resulted in the death of ten men. This explosion brought the number of "major disasters" for the present year to 3 with a loss of 135 lives, while the first three months of 1922 showed 6 similar disasters with 71 lives lost.

Comparing the fatalities by causes for the first three months of 1923 with the corresponding period of last year, the figures for 1923 show reductions in the fatality rates per million tons from falls of roof and coal, haulage, and explosives. The rate for electricity has remained practically unchanged, while that for gas and dust explosions has increased about 66 per cent. The comparative fatality rates per million tons for the three-month periods were:

	1922	1923
Falls of roof and coal	1.819	1.703
Haulage	.760	.570
Gas and dust explosions	.600	1.000
Explosives	.193	.121
Electricity	.106	.103

No Coal Stringency in Interior of Germany After Three Months' Occupation of Ruhr

By H. O. Herzog

Berlin, April 12, 1923.—More than three months having elapsed since the occupation of the Ruhr began a comprehensive survey of the German coal situation resulting therefrom in the occupied zones and in the German interior is possible. From the beginning a policy was adopted of keeping up production as far as possible and of employing men not actually engaged in production in clearing up, repair and development work, to a large part at the expense of the state. After the first turmoil had passed production settled down to a rate of about 70 per cent of normal, which since then has slowly but steadily shrunk.

From the beginning of the occupation on Jan. 11 to the end of January, when the blockade of the Ruhr came into force, the fuel ready for shipment was rushed to the German interior. Since then shipments by rail have dwindled by degrees to an average of 35,000 tons per day, or 12 to 15 per cent of normal. This is attributed to disorganization of the railway system. In the main the shipments go to Italy (to which country the reparation supply is maintained), to Holland and Switzerland in fulfillment of standing export contracts, and to consumers in the occupied parts. Shipments by water have almost stopped, the most important water-way, the Rhine-Herne Canal, having been blocked by two scuttled coal barges.

In addition to the officially recorded shipments a large part of the output is shipped over private junctions and by road vehicles to large consumers in the proximity, chiefly cokeries and iron works. Cokeries are so well supplied that during the three months of occupation they have been able to maintain their usual rate of production. Consumers have taken up rather more than their requirements in order to relieve the already congested pitheads. Nevertheless accumulations of coal and coke were estimated at the end of March at nearly 7,000,000 tons.

Organization Efforts of French Futile

This has been accomplished in spite of efforts by the occupying force to organize the removal of fuel. These efforts were first concentrated on the transportation problem, which presented far greater difficulties than had been anticipated. The German railway force lends no help whatsoever in this respect; on the contrary, carefully devised acts of sabotage are found a great hindrance. The automatic control employed in the network of railway lines in the Ruhr lends itself particularly to such a policy of obstruction. All junctions in the heart of the district are controlled from a central station, which has most effectively been put out of gear. The congestion of traffic in this part of the district has become so great that it defies all remedial efforts under present circumstances. It will take many weeks after the restoration of normal conditions to disentangle it. Conspicuous in the jam are a large number of fully loaded coal trains which neither party is able to shift one inch.

In view of such conditions the occupying force has restricted its efforts to the northern part of the system, which, being detached from the network in the interior, offers the least difficulties. Of the 1,600 miles of railway lines in the Ruhr about 400 miles have been put into commission by the occupying force. Service at a greatly reduced extent is maintained on them by makeshift methods. Similar conditions prevail with regard to the loading operations. The passive resistance in this respect is highly organized.

When the mines receive warning of approaching seizure, the hoisting and conveying machinery is rapidly but effectively put out of gear and its connection with the power house is severed. Essential parts are removed and hidden. To replace them is nearly impossible without an intimate knowledge of their design. In consequence the alien engineers have to resort to the most primitive methods of loading —by shovels, baskets and wheelbarrows. The headway made is therefore extremely slow. According to an official German statement the total of fuel removed by the occupying force from the beginning of the occupation up to the end of March amounts to 230,000 tons of coal and coke compared with a preoccupation supply which for the time indicated would have been 4,200,000 tons.

When it is remembered that 500-ton trains used to leave the Ruhr for France and Belgium at intervals of 10 minutes during 20 hours of the day and that nearly one-fourth of the German working force was employed for these shipments, it seems impossible that more than a small fraction of the usual reparation supply can be removed while passive resistance is in force in the entire district. No wavering in the resistance is observable; on the contrary, occasional acts of sabotage are committed such as the destruction of the Rhine-Herne Canal, which was about to be reopened to traffic. The concrete structure of the canal spanning the river Emscher was blown up at the point of crossing, the canal thus being laid dry for many months.

German Interior Gets No Ruhr Coal

The situation in the German interior, against which the Ruhr blockade is chiefly directed, has withstood the strain considerably better than could have been expected. The fact is clearly shown that the coal reserves in the country at the beginning of the occupation were much larger than was commonly assumed and officially stated. Since the end of January no Ruhr coal has reached the German interior, except the output of several mines in a detached area east of the occupied zone, having an average output of 400,000 tons of coal and 100,000 tons of coke per month, which has been gradually increasing. Apart from these mines the German supply rests now solely on the output of Upper Silesia, Lower Silesia and Saxony, in addition to the Central German brown coal output.

The three coal fields named produce a combined monthly average of 1,600,000 tons of coal and 230,000 tons of coke. Efforts to increase this output by overtime and work on Sundays have failed, indicating that the labor situation is not so well in hand as official announcements proclaimed. It showed in February even a drop compared with the January output. In March a larger falling off was noted owing to strikes in Upper Silesia. Production of brown coal has been increased slightly, but the remarkable fact developed that the increase was not readily absorbed by the market.

Imports have in no way assumed unusual proportions. The expected wild rush for foreign coal has not materialized, although British coal was temporarily cheaper than German. Total coal imports in January were 1,870,000 tons, which corresponds with the average of the latter part of last year. Five hundred and forty-two thousand tons of this came from Great Britain and 1,230,000 tons from Poland. The size of the latter quota is unusual. A considerable part of it came from Poland proper. As the amount exceeds the usual surplus available for export from both Polish Upper Silesia and the Dombrova basin combined it cannot be considered a permanency, especially as Austria, Hungary and Italy in part, as well as other small surrounding countries are dependent on the Polish supply. It was obtained by Germany by rushing all available rolling stock to the mines, thereby outdistancing other bidders that are not in so fortunate a position. Imports from Poland have since fallen to the normal of about 600,000 tons per month.

British imports, on the other hand, have risen to over 1,000,000 tons. The supply of Bohemian brown coal, which approaches in quality the low grades of bituminous coal, has been increased to nearly 300,000 tons per month. Dur-

ing March British imports further increased. In addition a number of orders were placed with the American market. The first consignment of American coal of 12,000 tons arrived early in April. South Africa is under consideration as a further source of supply. Negotiations in this direction have led to business on a small scale.

Imports during the first three months of the year averaged 2,000,000 tons per month. Only a small part of this quantity can be looked upon as in substitution of the 4,000,000 tons of coal and coke usually supplied by the Ruhr, unless it be assumed that last year's imports were not for actual demand but as a provision against an emergency like the Ruhr occupation, which indeed has been an impending danger for nearly two years. This assumption is corroborated by the fact that after three months of Ruhr occupation no actual stringency in the German interior is in sight. Husbanding measures by the authorities are peculiarly absent; as an illustration it may be mentioned that the embargo put on coal-tar products has been lifted on the ground that the coal situation turned out to be more favorable than had been previously assumed.

There is not the shadow of a doubt that the coal situation during the first months of the occupation has been largely supported by reserves. German demand will therefore become more pressing as these reserves dwindle. On the other hand consumption is gradually decreasing in proportion to the growing business depression. The latter is in no way a consequence of the Ruhr occupation, as is frequently supposed erroneously, but is chiefly due to the marked stabilization. In this respect the situation gives signs of growing distress. German imports have increased largely as the result of the artificially high mark rate, which has forced German prices above the world market level. Exports are declining in equal proportion, thus further widening the gulf in the country's foreign trade balance. The present situation is maintained under an enormous financial strain, evidenced by the rapidly rising flood of internal indebtedness. The government's scoop on the hoarders of foreign money by the mark stabilization combined with a severe curtailing of credits has considerably weakened the financial position of the industry. The question of how long Germany can maintain her front has become chiefly a financial problem. It can clearly be seen that Germany's remaining strength is being spent at a rate which she cannot hope to maintain much longer.

Northwest Rate Fight Starts This Week

The battle before the Interstate Commerce Commission over Northwestern coal rates was scheduled to start on Wednesday of this week at Minneapolis in hearings on five complaints. The dock operators are appealing for an increase in rail rates to the Northwest from Illinois, Indiana and Midwestern fields and the states thus attacked are lining up their defense.

The case of the dock operators has been pretty well explained to the U. S. Coal Commission so that the Illinois and Indiana men go into the hearing feeling they know what sort of ammunition their opponents are going to use. They have kept a tight mouth about their own case but they expect to tell the commission that they see no reason for making the people of the Northwest pay higher prices for coal just because the docks cannot meet rail competition. Furthermore, they will point out that the docks are not robbed by rates of quite as much territory as they claim although it is a fact that Illinois coal can be laid down in the Twin Cities for approximately 50c. a ton cheaper than dock coal. North of that point the field is a fair one with no favors, though the dock men will point out that Illinois coal can reach Minneapolis for $3.46 and then proceed to Duluth for an additional 31c. whereas it costs $1.82 to ship a ton from Duluth down to Minneapolis.

The case is an extensive one and may take a month for the first hearing alone. The further procedure that invariably follows in such a case is bound to drag it along for months if not for years. Illinois men are saying that it is foolish for Northwestern buyers to delay purchasing in the hope that a new rate schedule will be worked out this summer.

Docks are not buying heavily for summer stocking yet, but this is attributed to the many consolidation deals that still impend. No dock owner wants to be caught with heavy supplies on hand if he is to be absorbed in a combine.

Illinois Legislators Angered at Herrin Officials in Public Quiz

Dumbness, bad memory, evasion, defiance and all other sorts of defence which officials of "bloody Williamson" County raised last week to protect themselves in a public investigation at Marion, Ill., did not discourage a legislative committee which is trying to find out why troops were not sent to Herrin last summer in time to prevent the massacre. The committeemen grew irate and verbally flayed two or three of the witnesses and learned little that is valuable to them, but they did not give up the job. Warned that they had better stop such an investigation lest something happen to them, the committeemen declare they will take the investigation up the state to Springfield, the capital, and there compel full testimony or inflict grievous punishment.

Under questioning by the committee three men who were deputy sheriffs at the time of the massacre brazenly said they did not do anything to stop the attack on the Lester strip mine at Herrin because they did not know anything was going on. One man declared he did not intend to tell the committee anything either in Marion or anywhere they might summon him. Melvin Thaxton, who was sheriff at the time but who is now County Treasurer, could not satisfactorily explain to the committee why he had told Colonel Sam Hunter, of the state militita, that he had twenty deputies ready when as a matter of fact he had only three, nor why he considered the riot situation "in hand" while an armed mob marched unhampered to its bloody work, nor why he went away on the morning of the massacre, nor anything else. His answers were bland and dull.

Though it was plainly evident all week to the legislators that they were extremely unwelcome visitors in Williamson County, and mutterings were heard on all sides, they stuck to their job and quizzed every witness they could get. Some "could not be found."

Among other witnesses was Delos Duty, State's Attorney, who helped conduct the murder cases against two groups of the many United Mine Workers indicted for murder of the twenty-two non-union strip miners killed after they had surrendered under their flag of truce. Duty admitted he knew the night before the massacre that two union men had been shot down near Carbondale, a few miles from Herrin, by somebody, presumably guards of the imported strip miners. Yet in spite of that he told the committee he did not think the situation was as serious as it turned out to be and therefore he did not insist upon state troops coming in. He said Colonel Hunter that evening telephoned Adjutant General Carlos Black that "all was quiet." Colonel Hunter denies this telephone report to General Black and took a member of the committee to the local telephone office, where no record of such a call on that night was to be found.

William H. Warder, an old attorney of Marion and regarded as a most substantial citizen, told the committee that he was active before the massacre in trying to organize a citizens' committee to prevent trouble. He said that if he had been the adjutant general of the state he would have gone to Herrin personally on the strength of the grave reports which he knew Colonel Hunter turned in. He praised that officer for his efforts to get troops to the scene of trouble.

"Do you believe that troops could have prevented what happened?" a committeeman asked.

"If properly handled, yes. If not, they might have caused something much worse," he replied.

All in all, the legislative committee thus far has discovered little in the quest to learn why troops were not sent to Herrin after Colonel Hunter "repeatedly" asked for them. Adjutant General Black insists Colonel Hunter made no such requests. Witnesses in Williamson County have testified on both sides of this point. Some heard Colonel Hunter picture the situation as exceedingly dangerous and others heard him say "all is quiet." Adjutant General Black is trying to dismiss Colonel Hunter from the service.

Increase of 2,000,000 Tons per Month in Continental Demand for British Coal Laid to Ruhr Occupation

The occupation of the Ruhr and the practical elimination of Ruhr coal from European markets is causing an added demand of more than 2,000,000 tons of British coal per month for Continental consumption, according to a statement prepared by the Western European Division of the Department of Commerce. The statement continues:

"British coal exports are increasing and the price of coal is rising. The quantity available for domestic consumption is considerably in excess of last year. Production in the British iron and steel industry is now 50 per cent in excess of the 1922 figures and only slightly below the pre-war average. In the face of these facts, the loss of production during the Easter holidays, amounting to nearly 3,000,000 tons, is considered important.

"In 1922 British coal production amounted to 252,000,000 tons, of which 82,000,000 were either exported or used for foreign bunkering, leaving 170,000,000 for home consumption, an average of 3,150,000 tons per week. During February an average of 5,537,000 tons was produced weekly, of which 1,925,000 went abroad, leaving 3,612,000 for home consumption. In March an average of 5,510,000 tons was produced weekly, of which 1,930,000 tons went abroad, leaving 3,580,000 tons for home consumption. March exports of coal amounted to 7,180,000 tons. For February and March the margin of coal for domestic consumption was only 14 per cent above the monthly average for 1922, while demand for coal has increased to a much greater extent.

"One method of calculating the increased demand is a comparison of steel production. The monthly average production of steel ingots and castings during 1922 was 486,000 tons. In January 624,000 tons were produced, or 30 per cent above the 1922 average. In February 707,100 tons were produced, or 48 per cent above the 1922 average. In March 802,500 tons were produced, or 65 per cent above the 1922 average. With the steel industry producing at a rate more than 50 per cent above last year's average and coal production but 15 per cent increased, it is considered not surprising that coal prices have risen until the best grades of South Wales coal are quoted at over £2 a ton for export.

"The increased Continental demand for British coal during February was partly accounted for as follows: France imported 1,375,000 tons, 375,000 above the average before the Ruhr occupation; Italy imported 675,000 tons, or 175,000 above previous imports; Germany imported over 1,000,000 tons, or 250,000 more than the average during 1922; Belgium imported 425,000 tons, while previously almost no British coal was consumed in that country. Additional shipments for German account probably are contained in the figures for Holland and Denmark, while these countries used increased quantities of British coal on their own account in place of supplies previously obtained from the Ruhr. In March France and Germany each imported 1,800,000 tons of British coal, or a combined excess of 1,750,000 tons above the 1922 monthly average. While the situation in the Saar basin is partly improved by the return of some of the strikers to work, production is still below normal. This causes additional demand upon the French coal reserve. Altogether, it is apparent that as long as the Ruhr deadlock continues, western Europe is facing a probable net shortage of coal, which provides an opportunity for shipments from the United States. Under these circumstances, the loss of production in Great Britain due to the Easter holidays is significant.

"For the week ending March 31 British coal production was 4,874,000 tons; for the week ending April 7 it was 3,941,000 tons a combined net loss of almost 3,000,000 tons from the average figure of 5,700,000 tons per week previously maintained. However, the latest returns show that during the week ended April 14, 5,776,000 tons were mined, the largest weekly output in the last four years."

Merge Five Pittsburgh Coal Companies

The Bertha-Consumers Co. was organized in Pittsburgh, Pa., April 25, representing a merger of the Bertha Coal Co., the Consumers Fuel Co., the Consolidated Fuel Co., Marshall Fuel Corporation and the Jewel Coal Co.

The new company has a capital of $10,000,000, and the annual production at present is 6,000,000 tons, with immediate development contemplated to existing properties to make it 8,000,000 tons. There are twenty mines involved, and 40,000 acres of coal land, located in Pennsylvania, Ohio, West Virginia and Kentucky. The combined organization has 1,000 stockholders.

John H. Jones, of Pittsburgh, is president and founder of most of the companies merged. Most of the companies were of themselves mergers of smaller companies in the past. The merger becomes immediately effective, and is one of the largest that has taken place in the Pittsburgh coal fields in years. The general offices of the company are in Pittsburgh.

Head of Williams & Peters Dies

Richard H. Williams, of the coal firm of Williams & Peters and also a director of the Federal Reserve Bank of New York, died Saturday, April 28, at his home, 4 West Fifty-first Street, New York City, after a short illness. He was in his sixty-ninth year. He was born in New York City and was educated at private schools and at Columbia University. After leaving college he helped to organize the firm of Williams & Peters, coal dealers, at 1 Broadway, and was its senior member at the time of his death. Since 1885 the firm has handled the anthracite business of the Erie R.R., which includes the Pennsylvania Coal Co.

On being appointed to the Federal Reserve Bank directorate, Mr. Williams resigned as a director of the National Park Bank and the Fulton Trust Co. He was a director of the Pennsylvania Coal Co., a director and member of the executive committee of the Equitable Life Assurance Society, a director and member of the finance committee of the Atlantic Mutual Insurance Co., and a director of several other corporations. He was generally known as a banker rather than as a coal man.

He was a member of the Sons of the Revolution and the Mayflower Descendants and also held membership in many clubs.

Mr. Williams leaves a wife, who was formerly Miss Sarah Welford Peters; a daughter, wife of the Hon. Cecil Campbell, of London, and a son, Richard H. Williams, Jr., of New York City.

Funeral services were held Monday morning at 10 o'clock at Grace Episcopal Church, Broadway and Tenth Street.

Commission Issues Retail Questionnaire

Through its retail section the U. S. Coal Commission has sent to retail dealers a new questionnaire designated R-70, which requires among other data, the form and date of organization, and the names of officers, directors and stockholders. Later pages ask for a copy of the balance sheets, profit and loss statements and the amount of loans outstanding for the years 1918 to 1922, inclusive.

Costs are classified under three general heads: general and administrative expenses, yard expenses and delivery expenses, with twenty-six separate items distributed among these three main heads.

WE DON'T NEED a nationalization of the coal industry, but we do need a rationalization of the coal miners.—*Cleveland Times.*

Midwestern Coal Sages Foresee Good Summer and Autumn Business

There is some optimism among midwestern wise men of coal. They look forward to the summer with hopes of a steadily though slowly rising market and of the movement of more summer coal than ever before. There are several reasons assigned: The "stock-now" propaganda is beginning to have a slight effect already. Most coal buyers can see for themselves that railroads probably will be jammed with freight next winter and unable to handle a tremendous volume of coal in the cold months. Nobody knows whether the soft-coal miners will strike again next April or whether the anthracite men will choose to quit Sept. 1. It will soon dawn on the country that in view of the present conditions of transport and coal demand prices are now at rock bottom and there is no point to waiting for another drop.

The "stock-now" campaign, strenuous though it has been officially, is only just beginning to sink in where it will do the most good. For instance, the railways announced they were going to stock heavily during the summer starting at once so as to get much of their own coal off the lines before the autumn rush. Few have done anything about it. In the Middle West the Burlington is the first to act, principally because President Hale Holden was one of the men most active in the stocking program recommended to all roads. His company is now busily putting 500,000 tons on the ground at various points from Chicago westward. The Wabash is putting down 200,000 tons, which represents only thirty days' normal consumption. Most other roads in the middle section of the country are only talking about it. It is believed they will all act soon, however.

Car-loading reports running over 900,000 cars a week are pretty good arguments to support the statement that railroads are going to be so busy the rest of the summer that nobody can count on them being anxious to haul a great burst of coal next autumn, when general freight is almost sure to be even heavier than it is now. This fact also is sinking home on coal consumers. While there appears to be plenty of coal equipment ready for the use of mines right now, the fact is that if any considerable number of mines now shut down were to reopen, this supply, running up to 100 per cent in spots such as on the Illinois Central in western Kentucky, would be stretched out thin. This is one of the reasons why prices show a tendency to turn and rise, though they still remain low throughout the Middle West.

As one sales manager of a great company sees it: "We'll have a steadily rising business from June 1 to Dec. 15. Then there will be a drop. We will be wondering where our usual winter market is. It will have been filled in advance. This country is going to see the greatest stocking movement in years. Already it is starting among retail dealers in the bigger cities, and it will spread."

They Sling Mud at Each Other in the Illinois Union of Brotherly Love

John L. Lewis, president of the United Mine Workers, is not the only mine union leader who has his Brophy. Frank Farrington, president of the Illinois miners, has his in the person of John J. Watt, secretary-treasurer of the union sub-district centering at Springfield, Ill. Watt has worried Farrington politically at every opportunity. Recently he made a veiled charge that Farrington was mishandling the Herrin defense fund of 1 per cent per month assessed against every Illinois union miner, which now totals $800,000, according to Watt. This was grounds for an appeal to President Lewis to unseat Farrington.

Reaching that point, the row broke out in full-page advertisements in Springfield papers. Watt challenged Farrington to debate "The Evils of the Present Illinois Compensation Law," declaring the Ohio compensation law is better and should be adopted in Illinois. Farrington shied around the debate, charging Watt with being an "under-cover man," treacherous to the union and planning to try to cause a wildcat strike in Illinois so as to shatter the union organization. Watt replied with various and sundry squirts of mud, bringing to light the fact that John L. Lewis said that Farrington, Vice-President Fishwick and Robert M. Medill, director of the Illinois Department of Mines and Minerals, split money three ways in return for making a compact with William J. Lester permitting Lester's company to strip the coal whose ultimate loading caused the Herrin massacre.

And so the battle goes merrily on in the papers, leading from one subject to another, at so much a page, with the membership of the United Mine Workers as the bleachers crowd looking on and hooting approval of the hot shots and violent epithets each union official casts at the other under the salutation: "Dear sir and brother." A pleasant time is being had by all.

J. P. Cameron, Pittsburgh Operator, Dies

John P. Cameron, forty-three years old, a member of the Pittsburgh coal firm of Crawford & Cameron, died suddenly of pneumonia Monday, April 23, at his home in Pittsburgh. He had been ill only three days.

Mr. Cameron was born in Houtzdale, Pa. In 1911 he became associated in business with L. F. Crawford, handling electrical mine supplies. He was president of the West Branch Mining Co., a director of the Peale, Peacock & Kerr Co. of New York; vice president of the Lindley Coal Co., a director and treasurer of the Jefferson Gas Coal Co., a director and treasurer of the Jefferson Coal & Coke Co., a director of the Goodman Manufacturing Co. of Chicago, and was president of the Royal Coal Co. During the war Mr. Cameron was a member of the Fuel Administration, stationed in Altoona.

JOHN P. CAMERON

Mr. Cameron leaves one son, William R. Cameron; three brothers, A. P. Cameron, of Irwin, Pa.; S. P. Cameron, of Girard College, Philadelphia, and William R. Cameron of Philadelphia, and five sisters, Mrs. George S. Ramsey, of St. Mary's, Pa.; Mrs. H. R. Hoard, of Philadelphia, Mrs. George H. Gearhardt, of Lexington, Ky.; Miss Anne R. Cameron, of Philadelphia, and Miss Christine M. Cameron, of Philadelphia.

Government Fuel Yards Ask Coal Bids

Bids for furnishing 201,800 tons of low-volatile coal to supply the fuel requirements of the Government Fuel Yards in Washington, D. C., were asked April 28 by the U. S. Bureau of Mines.

The total tonnages and the kinds of coal required are as follows: 4,750 tons New River nut and slack through 2-in. screen; 170,500 tons New River run-of-mine; 25,000 tons Maryland, Pennsylvania, or northern West Virginia run-of-mine; 1,600 tons gas over ¾-in. screen. Under the specifications, deliveries must be made during the period from June 1, 1923, to March 31, 1924.

Bids to furnish the coal required will be opened by the Chief Engineer of the Government Fuel Yards May 15, at 2 p.m.

REPRESENTATIVES OF FEDERAL FUEL DISTRIBUTOR WADLEIGH have completed their studies of the question of community coal storage in Chicago and began similar studies in Indianapolis this week.

Coal Commission Seeks Means to Prevent Strikes; Hammond Deprecates Government Control

By Paul Wooton
Washington Correspondent of *Coal Age*

An impelling reason why operators and mine workers should devise means to reduce the possibilities of coal shortages is the growing conviction that emergencies in the future will be met in a more drastic way than were those of the past. The President's Coal Commission is urging that constructive suggestions be brought forward. The way now is open for anyone to suggest how mine operators and mine workers can live together with less discord. It is admitted that if there were no coal strikes, coal emergencies would be few. If there is no assurance that strikes are to be fewer, probabilities seem to point to the proposal of legislation which would set up special machinery which could be called into use whenever an emergency threatened. There is reason to believe that experience during the emergencies of the last few years has been such as to condemn any halfway measures. The organization that may be proposed most likely will be along the lines suggested by General Goethals, that is, to empower the President to appoint a fuel administrator in the face of an emergency. Such an administrator would have the powers of a dictator whose orders could not be interfered with by the Interstate Commerce Commission or any other federal body or official, save the President himself.

The members of the Coal Commission who just have returned from a visit to the anthracite region saw much in which they were interested. Chairman Hammond declares that the engineering practice among the large anthracite producers is splendid and is much ahead of that in the bituminous fields. The physical production of anthracite, he stated on his return, is handled so well that no radical improvement can be suggested or expected. The mining is well done and he doubts if any material economies can be effected under present conditions. He pointed out, however, that his observation is a general one and is not based on the detailed study, the results of which will be available later, being made of the coal that is left unmined.

The existing machinery for conciliating differences between operators and their employees impressed Mr. Hammond very favorably. While in the anthracite field, however, he heard some complaints that the time required to pass upon grievances is excessive. The commission will discuss the possibilities of making suggestions for the improvement of conciliation procedure and will consider whether or not such machinery could be employed to advantage in bituminous districts.

The main difficulty in anthracite comes in its distribution, Mr. Hammond said. Unnecessary turnovers result in high prices to the ultimate consumer. This reference was independent of the question of royalty. No attempt was made on the anthracite trip to investigate that factor in anthracite costs. This is to be taken up actively. Among those who will be heard on the subject is Senator Pepper, of Pennsylvania.

Mr. Hammond expressed particular interest in the stripping operations. He saw no evidences of destitution at any point visited by the commission. There were some indications of lack of thrift on the part of some of the anthracite workers. He spoke favorably of the housing provided by the companies, but did observe some bad housing conditions in the small towns outside of company jurisdiction. The members of the commission climbed around some underground, but Mr. Hammond is not strongly impressed with the advantages gained from such visits. They are necessarily hurried and it is probable that such trips into the bituminous fields will be limited.

The members of the commission discussed the labor situation with representatives of the operators and of the miners and urged them not to wait until the last minute to reach an agreement. Mr. Hammond's personal conclusion is that an amicable settlement will be reached.

Amplifying the thought expressed the week before by Governor Marshall, Chairman Hammond voiced the hope that the commission will receive more constructive suggestions now that it is reaching the point where conclusions must begin to take shape. He said that he does not want to see nationalization of mines or any more government control than is necessary. He suggested that leaders among the mine workers and among the operators arrange conferences in the hope of ironing out some of their internal troubles.

During the course of Saturday's conference Mr. Hammond reiterated his belief in storage. He still believes greater elasticity in operation can be effected if some storage is provided at the mine mouth. He commended the policy being pursued by the public utilities in providing ample reserves of coal.

Exchange of Trade Information Through Associations Again Up in Supreme Court

Arguments were presented April 25 and 26 before the U. S. Supreme Court in the case of the government against the American Linseed Oil Co. and others, involving the right of business to exchange trade information through associations or through private bureaus acting as clearing houses for such data. The case is considered to be the most important to trade associations since the hardwood lumber case, but it involves different questions than the latter.

The federal government alleged that by exchanging various forms of information which were distributed as statistics by the Armstrong Bureau of Related Industries the defendant linseed oil companies created a condition tending to prevent competition in prices of their product. The U. S. District Court for Northern Illinois, where the suit originally was instituted in 1921, held for the defendants and ordered the suit dismissed, the government appealing.

In arguing before the Supreme Court, Special Assistant Attorney General James A. Fowler declared that daily and instantaneous price reports were sent the bureau by the linseed oil members, and relayed back to the members by the bureau, charging that each day each member knew the prices quoted by his competitors.

Thomas M. Debevoise appeared as attorney for the American Linseed Oil Co. and John Walsh, formerly chief counsel for the Federal Trade Commission, appeared in behalf of the Armstrong Bureau and other defendants. They argued that while various statistical information was exchanged through the bureau, there was no restriction of output and no combination or agreement as to price. Prices of the oil followed the flaxseed market, they argued. The right of business corporations to compile statistics on which to base judgment was upheld, they contended, by the fact that the Department of Commerce gathers and distributes statistics of business.

The Quartermaster General of the Army has called for bids, to be opened May 9, covering the following coal requirements: Fitzsimmons General Hospital, Bunell, Colo., 1,000 tons; Fort Sam Houston, 3,000 tons.

Bids to be opened by the Army on May 3 cover the following coal supplies: 3,000 tons for Rock Island Arsenal; 1,000 tons for Fort Riley, Kan.; 3,650 tons for Fort Leavenworth, Kan.; 2,000 tons for Fairfield Air Depot, Osborn, Ohio; 1,000 tons for Fort Benjamin Harrison, Ind.; 600 tons for Fort Crook, Neb.; 700 tons for Fort Des Moines, Iowa; 1,000 tons for Fort Omaha, Neb.

Take Coal Cases to Supreme Court

Three coal cases involving the U. S. Government have reached the U. S. Supreme Court. In one case the government has filed a motion to dismiss the appeal of the Corona Coal Co. in a suit for additional compensation for coal requisitioned by the Railroad Administration. The coal company brought an action in the U. S. Court of Claims for $107,431.99, the difference between the contract price and the Fuel Administration price.

In the other two cases the Supreme Court has signified its willingness to hear arguments in the actions brought by Willard Sutherland Co. and by William C. Atwater & Co., Inc., against the United States, the question at issue being whether certain contracts with the Navy Department are to be considered "requirements" contracts and whether under them companies can be required to furnish excess tonnage at the contract price.

Never Averaged 200 Days Work per Year, Says Union Plasterer

Interesting evidence on the irregularity of employment among plasterers was brought out April 24, in the Criminal Branch of the New York Supreme Court, where thirty-six members of the Plasterers' Union, Local 60, are on trial, charged with conspiracy in connection with building operations in New York City from 1920 to 1922. Michael J. Colleran, president of the union and also president of the new Building Trades Council, testified that there were less than 200 working days in the year for plasterers.

As "irregularity" and "seasonal nature of the industry" never fail to play a prominent part in criticism and investigations of the coal industry, the following excerpts from Colleran's testimony should prove of more than passing interest:

Q—Under Art. 10 of the constitution with relation to wages, Sec. 2 of that article provides that your men are only to work on Saturday a half day. Now what I want to know is if the men only work a half day on Saturday, do they get a full day's pay or do they only get paid for a half a day?

A—For a half a day.

Q—And any of these holidays that have been enumerated, are those holidays with pay, or holidays without pay?

A—Without pay.

Q—Now, I also asked you before concerning the amount of time—the amount of days—that you in your experience, estimated that the men could work in the plastering industry. Will you give me the figures on that again?

A—Do you mean approximately how many days a plasterer can work?

Q—Yes, during the year.

A—During the year. I will have to in my own way do that.

The Court—Hasn't that been figured by the State Labor people? Somebody said 210 days.

Mr. Goldstein—The State figured it out but I want to show how he arrives at his figures.

Witness—There is 52 Sundays on which there is no work done. There is 52 Saturdays which would constitute half a day, which would constitute 26 whole days. There is eleven holidays. A total of 89. There is 89 days that work is not to be done at all. Eighty-nine from 365.

Mr. Untermyer—You mean except as overtime.

Witness—With the exception of overtime. That is 276 days. Our trade being a seasonable trade, you take the months of December and January. After we leave this commercial district and go out into the apartment houses and so forth, those two months are practically nil as far as work is concerned. That would be sixty days taken from that, which would make 217 days.

The Court—We have already taken out eight of those for Sundays and Saturdays.

Witness—Yes, that is counting those in.

Mr. Untermyer—That is besides the holidays.

Witness—Yes, I am bringing it down to show that around 210 days would be the approximate of all the days that a man could work if he had the work to do, and then when you figure in the heat of the summer, when the laborers quit, you lose a day or two days. In the spring of the year when it rains, the laborers quit, you lose one or two days, that is in a week—one or two days in a week—and also when the job is complete you are laid off, requiring you to go out the next day and look for a job. Taking all those into consideration you do not make 200 days. I think I worked about as much as any plasterer in the organization when working with the tools, and I never averaged anything over that.

Charge Dock Operators with Monopoly

The Northwestern Coal Dock Operators' Association, Minneapolis, Minn., its officers, directors and members have been cited in formal complaint by the Federal Trade Commission charging a conspiracy to suppress competition and create a monopoly in the sale of anthracite and bituminous coal at wholesale and retail in the Northwest territory. The complaint alleges both a violation of the Federal Trade Commission Act, because of unfair competition, and of the Clayton Act by reason of price discriminations. Thirty days are allowed to file answer, after which time the case will be set for trial.

It should be borne in mind that the issue of the commission's complaint is merely a citation which states the commission's reason to believe, based upon preliminary inquiry, that the charges of the complaint are true; in other words, the complaint simply initiates a proceeding to get at the facts in an orderly legal manner.

The officers and directors of the association named as respondents are: President, W. W. Broughton; Vice-President, J. L. McMahon; Secretary, W. A. Prinsen, and directors W. W. Broughton, Peter Reiss, H. E. Smith, E. N. Saunders, Jr., E. A. Uhrig, J. L. McMahon, F. G. Hartwell and W. H. Goodwin. The members of the association named as respondents are Pittsburgh Coal Co. of Wisconsin, Minneapolis, Minn.; Northwestern Fuel Co., St. Paul, Minn.; C. Reiss Coal Co., Sheboygan, Wis.; Clarkson Coal & Dock Co., St. Paul, Minn.; M. A. Hanna Coal & Dock Co., Cleveland, Ohio; Carnegie Dock & Fuel Co., Pittsburgh, Pa.; Berwind Fuel Co., Chicago, Ill.; Northern Coal & Dock Co., St. Paul, Minn.; Great Lakes Coal & Dock Co., Minneapolis, Minn.; Pittsburgh & Ashland Coal & Dock Co., Cleveland.

It is stated in the complaint that the respondent companies are the largest distributors of both anthracite and bituminous coal in the Northwest territory and handle in the aggregate approximately 80 per cent of all coal passing over the docks of Duluth, Minn.; Washburn, Ashland, Superior, Sheboygan and Milwaukee, Wis. The "Northwest territory" as described in the complaint comprises the States of Minnesota, Wisconsin, North Dakota, South Dakota and portions of Iowa and Nebraska. Retail branches are maintained by respondent in the cities of Duluth, St. Paul and Minneapolis. It is in this territory that the commission has reason to believe that the respondents have suppressed competition and are obtaining and maintaining a monopoly.

Among the practices of the respondents which are challenged in the complaint are (1) circulation among the respondents of suggested price lists and official price lists before they are actually issued, it being generally understood that the prices so submitted would be maintained by the respondent companies issuing same; (2) circulating lists of retail dealers to whom the respondent refused to sell for any reason whatsoever with a key indicating the reason for such refusal to sell; (3) selling coal in the cities of St. Paul and Minneapolis at prices less than received for the same grade of coal at the same time in the same quantities in Duluth, Minn.; (4) arbitrarily cutting the price of bituminous coal to compel competitors to join the association and to cease selling below the respondents' list price and subsequently arbitrarily raising the price of coal after competitors had joined the association; (5) using a uniform contract with retail dealers and large consumers prohibiting the purchaser from diverting or using the coal for other purposes than outlined in the contract; (6) refraining from soliciting certain municipal business, recognizing such business as the prospect of the local retail dealer; (7) refusing to sell or ship coal to retail dealers in the country trade not equipped with the usual equipment of a retail coal dealer.

Sign New Wage Agreement in District 10

District 10, United Mine Workers, and the five remaining union coal companies in the State of Washington have signed a new wage agreement which will run until March 31, 1924, the basic rate being $7.50 for daymen instead of $8.25, which the miners desired. Work was resumed May 1.

Bituminous Operators' Committee Asks Probe of Miners' War Chest

Investigation of the uses made of an alleged $15,000,000 annual war chest obtained by the United Mine Workers of America through the "check-off" system, and complete abolition or regulation of that system, is requested of the U. S. Coal Commission in a letter from counsel for the Bituminous Operators' Special Committee, made public on April 30. Pointing out that union leaders "compel the operators to serve as tax collectors by requiring them to deduct these assessments from the pay of the workers," Colonel Henry L. Stimson and Goldthwaite Dorr, who signed the letter, charge that the funds thus raised constitute the commissariat of a tightening labor monopoly.

"The amount a miner must contribute to this taxation," the letter asserts, "frequently equals or exceeds what he has to pay for rent. In some districts the monthly tax has even run as high as $15 per man. In some districts the initiation fee has been set even as high as $75. Their monopoly cannot be achieved without this system of forced contribution. Time and again it has been shown that without the compulsory machinery of the 'check-off,' this organization cannot reach its monopolistic objective. Mine workers again and again have refused to support it except under compulsion. Its legitimate activities do not need the support of this burdensome taxation. . . .

"In order to help make these studies constructive and to furnish the basis for remedial action [against acts of violence] there is a thread running through them all which we ask the commission itself to follow. Campaigns such as these which the United Mine Workers have been carrying on require money in vast sums. As the cases already presented have shown and as those we are about to present will still further show, they are not spontaneous uprisings of men goaded by grievances; they are deliberate campaigns waged with a central, organized purpose, backed by a central, well-filled treasury. In order to understand how they can be carried on, this financial system must be understood; in order to prevent their recurrence and curb their excesses, this system must be abolished or regulated. . . .

"The huge fund of the United Mine Workers, stated to be in excess of $15,000,000, raised annually by this system of taxation is an outstanding fact of labor relations in the coal industry. The secret disbursement of this huge fund without public accountability, taken in connection with a nation-wide campaign of violence and of defense of the perpetrators of violence, is a sinister fact of this industry.

"We therefore respectfully suggest that no investigation into the facts of the coal industry by this fact-finding commission can be complete without a drastic public investigation into and airing of these facts. No remedy can be suggested until the magnitude of this evil is understood and corrective measures to curb it devised. We therefore request the commission to investigate the amounts which are raised annually by 'checking off' the dues and assessments and fines of the United Mine Workers of America from the wages of miners.

"We ask it further to end the secrecy that has shrouded the use of these funds and trace relentlessly—as it alone has the power to do—the application which has for years past been made of the vast sums thus raised. . . .

"We believe that the people of this country have no conception of the extent to which the United Mine Workers have disregarded, flouted and escaped the law in their campaigns to extend and protect their closed-shop monopoly. We believe they have little conception of the violence and magnitude of these same campaigns. The public is the chief party in interest before the commission. If the economic welfare of the nation, and the security of its fundamental institutions are being threatened by a militant monopoly, the sinister power of which depends upon its ability to use a great war chest without public accountability, then the nation is entitled to know this fact.

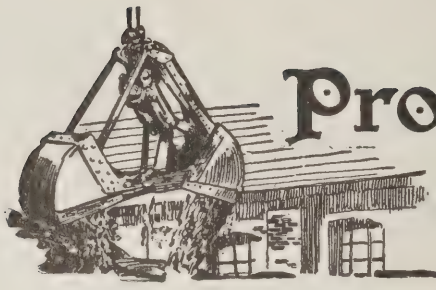
"We therefore believe that a complete investigation of the full facts is imperative in the public interest."

Miners' Union in Realm of High Finance

The current report of the auditors of the United Mine Workers of America, published in the *Mine Workers' Journal* of April 15, 1923, shows actual cash on hand as of Feb. 1, 1923, as $1,182,259.44. During the period under review—Aug. 1, 1922, to Jan. 31, 1923—the union raised more than two and a quarter millions. The actual receipts during the six months period were $2,786,140.38. The main sources of income were the tax of $927,250.19 and the assessment of $1,466,472.34. This is a total of almost $2,400,000, equivalent to about $4 per member.

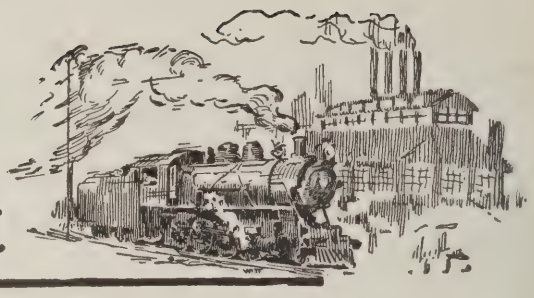
Included in receipts are the bank loans. They were $150,000 from the Indiana National Bank of Indianapolis, which has been paid back; $50,000 from the Harriman National Bank of New York, which during the period covered by the audit received payment of $150,000 in returned loans, and $50,000 from the Bank of the United States, New York City, which amount has likewise been returned.

Significant items, in view of the visit of President John L. Lewis to England, is a donation of $22,350 from British miners and a payment to the International Miners' Federation of $547.50 as dues.



The most interesting details are those of expenditure. For example, W. Jett Lauck, who has been retained by the U. S. Coal Commission, drew $14,000 during the six months for "preparing statistical data." District No. 7 and District No. 9 each got $10,000 as aid, and District No. 1 got $15,000. These are the anthracite districts. During the half year lawyers collected fees aggregating a trifle under $100,000. The largest single amount went to Earl E. Houck, designated as "assistant to the attorneys." For no specified reason Mr. Houck got $6,510.30, and for "legal expenses, West Virginia cases," he got $40,000. Besides these "legal expenses, West Virginia cases," nearly $5,000 was paid to attorneys in District 29, which has headquarters in Beckley, W. Va. This money was divided as follows: C. M. Ward, $1,200; J. E. Summerfield, $1,006.51; John I. Hutchinson, $2,250; Kyle D. Harper, $598.78; C. B. Summerfield, $227.50.

The firm of Hughes, Rounds, Schurman & Dwight got $21,452.39 for legal services in the Coronado case. William A. Glasgow, Jr., counsel for the International union, was paid $939.56.



The union holds no securities except $301,550 in U. S. Liberty and Victory bonds. Its cash is divided into $873,494.13 on deposit in the United States and only $47,952.52 on deposit in Canada. Outstanding checks amounted to $40,737.21 on Feb. 1. The recapitulation is:

Amount on hand, Aug. 1, 1922	$731,349.66
Income, Aug. 1, 1922-Feb. 1, 1923	2,786,140.38
Total	3,517,490.04
Expenditures	2,335,230.60
Balance on hand, Feb. 1, 1923	1,182,259.44

Representative Men in the Mining Industry considered the question of industrial relations at a luncheon given by the American Mining Congress Friday, April 27, at the Bankers Club in New York. Sydney J. Jennings, president of the American Mining Congress, presided and addresses were made by W. A. Grieves, chairman of the Division of Industrial Co-operation of the Mining Congress, on the work of that organization, and by J. F. Callbreath, on proposed enlargement of activity of the industrial co-operation division of the Mining Congress.

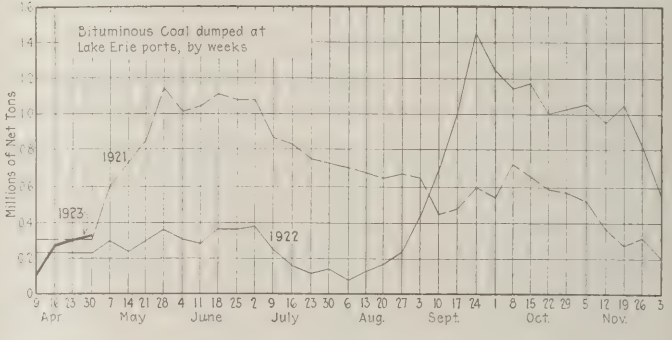
Production and the Market

Weekly Review

The record month of April has closed with production of over 42,000,000 net tons of bituminous coal, equalled or excelled in but one other April, that of 1918, when production was 46,000,000 tons. April usually is the low month of the year for the soft-coal industry. Spot prices of bituminous coal, though on the decline for the past four months, averaged higher in April, 1923, than in any previous April save 1917, before governmental war control of prices, and 1920, when price fixing ceased. The average spot price of soft coal at the mine, according to *Coal Age* compilations, was $2.88 per net ton in April, 1923, compared with $3.21 in April, 1917, and $3.85 in 1920.

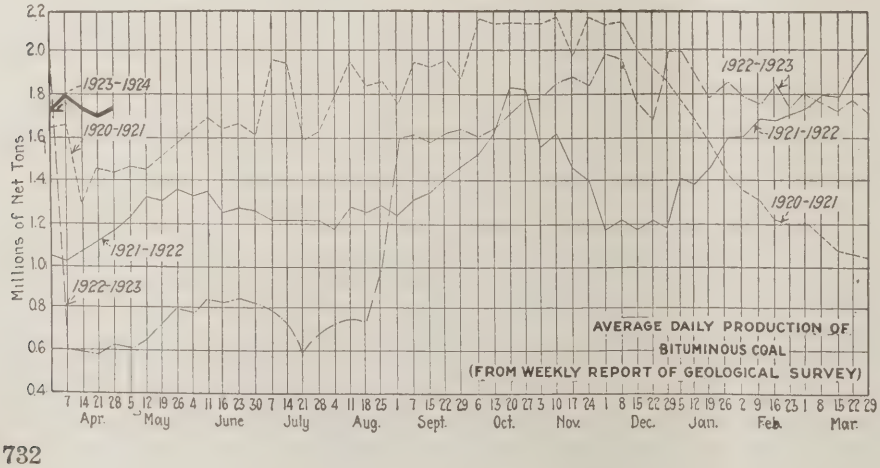
Anthracite, on the other hand, although running at top speed, is breaking no records. Total production in April was around 8,000,000 net tons, a familiar figure since it was almost reached in the Aprils of 1913, 1917 and 1921, and topped in 1914, 1915 and 1918.

Soft-Coal Prices Weak



The soft-coal market continues dull and all prices are weak. Inquiries for future business are increasing and the trade is waiting for Lake business to open soon and give some additional impetus to trading.

Smokeless, southern Illinois, eastern and western Kentucky, Somerset, Clearfield, Pittsburgh, Ohio and Kanawha coals declined in price last week. *Coal Age* Index of spot prices of bituminous coal declined 7 points from April 23 and on April 30 was 224. The corresponding average price is $2.71.



Each week more small operations are being closed because of low prices, particularly in central Pennsylvania, where many are hard pressed for orders. With the cheaper coals accumulating, producers are resorting to all means possible to move their product. The lack of orders in many districts has become more noticeable because of an improvement in car supply, this condition being principally attributed to limited production in Illinois, Indiana, southern Ohio and Cumberland-Piedmont districts.

Throughout the Middle West there is little activity and considerable urging is needed to move coal. The steam sizes are particularly sluggish in the Chicago market. There is a pronounced weakness in all grades in the Ohio markets with the exception of smokeless coals. Dealers are buying only to meet requirements.

Spot inquiry was light throughout the East, although there were increasing inquiries as to future business, with strong indications of heavy industrial purchasing soon. With embargoes in New England slightly modified there are indications that buying there will soon increase considerably. Little interest is being shown in May coal.

The general tone of the export market shows a slight improvement. Spot business to South America is a trifle more active. France continues to get considerable American coal, this being particularly true with regard to shipments from Baltimore, where 18 out of 29 vessels leaving that port during the first 21 days of April departed for France carrying 104,598 tons of cargo coal. From Jan. 1 to April 21 there have been 21 vessels leaving Baltimore for French ports with 121,310 tons of

Estimates of Production

(Net Tons)

	1922	1923
BITUMINOUS		
April 7	3,835,000	9,629,000
April 14 (*b*)	3,656,000	10,401,000
April 21 (*a*)	3,575,000	10,244,000
Daily average	596,000	1,707,000
Calendar year	140,354,000	169,416,000
Daily av. cal. year	1,485,000	1,789,000
ANTHRACITE		
April 7	9,000	1,602,000

(*a*) Subject to revision. (*b*) Revised from last report.

cargo coal. Coke movement for export is quiet, some distressed product being offered at low prices.

The lake situation is not yet in full swing. Heavy ice impedes traffic in the upper Lakes. There are many boats loaded at Lake Erie ports but they are not likely to be moved until after the first week of the present month.

"The present estimate of the total soft coal raised during the week April 16-21," says the Geological Survey, "including coal coked, local sales and mine fuel, is 10,244,000 net tons, which is 157,000 tons less than in the week preceding. It is, however, nearly three times the output in the corresponding week of a year ago, which was marked by the low point of production during the great strike. Preliminary reports of cars loaded in the week April 23-28 show a slight increase in the rate of production during the early days of the week and it is probable that the total output will be between 10,300,000 and 10,400,000 tons."

Dumpings at Hampton Roads for all accounts for the week ended April 26 totaled 323,855 net tons as compared with 377,538 tons dumped in the previous week.

Demand for domestic sizes of anthracite remains active. Most retail dealers complain of short supplies, while the steam sizes continue to accumulate and are draggy. Minneapolis and St. Paul retail dealers are laying in heavy supplies which so far have gone to them by rail, and they are looking forward to the opening of Lake navigation, when they expect increased shipments.

Midwestern Business More Sluggish

Every coal in the Middle Western markets needs a good deal of pushing just now and steam sizes are so sluggish that they hardly move at all no matter how vigorous the push. Southern Illinois screenings sagged until at the end of the week very little of it touched $2. Most of it moved at $1.75 or $1.80. Naturally all other steam coals were equally under downward pressure, with the result that a good deal of it moved at $1.50.

Southern Illinois domestic sizes are still moving at a little under the $3.85 price fixed on the circular, some of the worst selling down to $2.75. The increase to $4.10 effective May 1 did not force much buying. No other field

*Net tons, f.o.b. mines †Advances over previous week shown in **heavy type**, declines in *italics*.

Coal Age Index 224, Week of April 30, 1923. Average spot price for same period $2.71. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

except Mt. Olive has committed itself to a May price, everybody apparently expecting to pick off some of the sparse domestic business which the Franklin County people may lose by increasing the circular. Mt. Olive lump is to increase from $3.25 to $3.50. The cool of early spring persists in this region, thus keeping the immediate demand up for lump and egg sizes.

St. Louis Trade Is Quiet

An unusually quiet period prevails at St. Louis and probably will prevail for a few weeks. Very little storage coal is being put in except a little of the higher grades, such as anthracite and coke and some Carterville lump. There is no need for current use and the demand for Standard and Mt. Olive is off. Wagonload steam is light and carload steam is in a bad way, with very little moving. Country domestic is practically stopped and country steam is difficult to find. Indications are that there will be a good movement of early storage coal in May.

Retail prices advanced on Carterville May 1 so that the new prices are: Carterville, $7.75; Mt. Olive, $6.50; Standard, $5.75; smokeless, $14.50.

Kentucky Feels a Pick-Up

With better car supply in the western Kentucky fields movement of coal has been improving somewhat. It is reported that there is better demand from retailers for domestic sizes, due to the fact that retail yards are low, and while retailers are not planning to stock very heavily, they are taking a fair amount, believing prices are now at rock bottom. At the same time there is a good industrial demand for screenings, and prices are holding. Mine-run is not so active, but is moving fairly well.

More river coal is coming into Louisville now than for some time. Some concerns which haven't stocked much of it for the past several years, are planning to handle more this season.

Northwest Awaits Lake Coal

The market at Duluth remains tranquil, with the docks at low ebb, and prices firm. Buyers are holding off hoping that the new coal which will come up after the opening of navigation will be cheaper. There is no free anthracite on the docks and the bituminous unbought totals between 100,000 and 150,000 tons. There is a very evident disposition on the part of the consumers to buy anthracite early. Dock men place the probable price at about $1.50 lower than this year.

The coal business is at a standstill at Milwaukee pending the arrival of new supplies by lake. About fifteen cargoes destined for Milwaukee have been taken on at Lake Erie ports. The steamers will start as soon as the Straits of Mackinac are free from ice. A hopeful feeling prevails, and jobbers are looking forward to a busy May.

Retail prices on all-rail hard coal in the Twin Cities are advertised by one concern at $17.50 to $18 delivered for egg, stove and nut. Pea is $16. The soft coal trade is still awaiting developments, though wholesalers look for a considerably better season than that which just closed.

The Kansas market is dull. Such Missouri, Oklahoma and Kansas mines as are open run only two or three days a week. Those of Arkansas are getting even less. There has been no formal cut in prices. Householders are not buying, even in face of the assurance that the retail price of Arkansas semi-anthracite will advance at least 50c. early in May.

In Utah and the mountain states a cold snap during the week kept retailers busy but did not reflect itself in stronger demand upon the mines. There is very little general buying for steam purposes. Railroads are taking a little, but that is about all. No price changes in Utah coal have been announced.

Weakness Pronounced in Cincinnati

There was a pronounced weakness in all grades and sizes of coal, with the exception of smokeless, in the Cincinnati market, while comparison as made with the latter part of March show that the volume of coal on the open market was about doubled. On the other hand there is an increasing evidence of stocking going on in some sections. Orders are not numerous in the Columbus market and dealers are only buying what they actually need to meet requirements. Operators and jobbers in the Cleveland market say that due to the limited transportation facilities and heavier shipping to Lake ports, the volume of coal being offered in the open market is less than in some weeks, at the present rate of operations.

In the Pittsburgh district a few additional mines have closed on account of dissatisfaction with current prices. During the week ended April 22 there was a slight increase in production in the central Pennsylvania field, the output amounting to 18,084 cars as compared with 16,929 cars the previous week. Car supply improved slightly but not enough to keep the mines in continuous operation.

Buffalo reports little change in the situation. Stocks are running low but consumers appear unconcerned.

Inquiry and Receipts Low in New England

Spot inquiry in New England is extremely light. Aside from contract quotas, receipts have diminished and there is little tonnage available for distribution inland. Congestion at the re-handling wharves has been practically all cleared up, and prices on cars for best grades from the Pocahontas and New River districts range now from $8.00@ $8.25 per gross ton on cars. While the trade is hopeful

that prices will not now recede more than 25@50c. it is probable that by the end of May more radical reductions will take place. Buying is only on a hand-to-mouth basis.

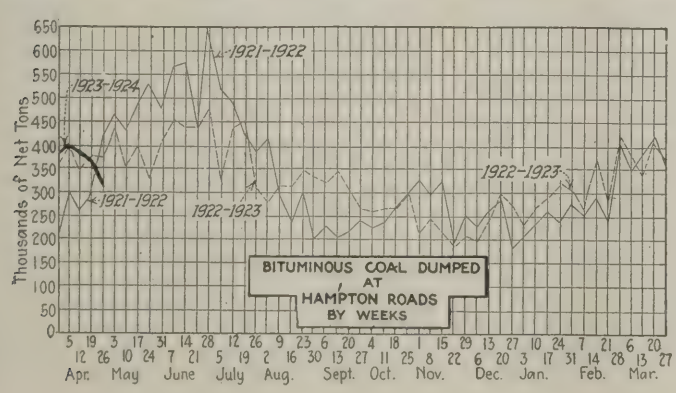
The spot market f.o.b. Hampton Roads shows no material change. Output is still much restricted, although accumulations at the piers continue about the same as for the past thirty days. There are few purchasers of single cargoes, practically all of the loadings being applied on season requirements, and the outlook for increased movement coastwise is by no means encouraging. The agencies are looking to the Lake trade to assist liberally in building up tonnage for the latter part of May and during June, but if conditions are no better in western Pennsylvania there will be strong competition from that quarter. Quotations are maintained about on the minimum base price named on the navy requirements, but distinctly there is a feeling that coal could be bought on offers at figures down to $6 f.o.b. vessel.

New minimum prices have been heard during the past week, but takers are not many and receipts are steadily diminishing. Even the producers of choice Cambria coals have made slashes in quotations previously made and are closely canvassing all the trade they have ever been in touch with to get spot business.

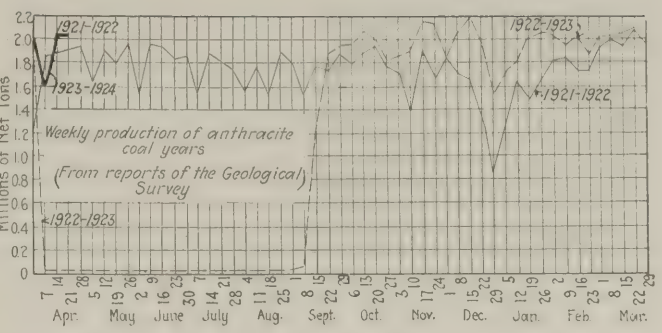
New York Buyers Look for Lower Prices

Buyers in the New York market expect lower prices, while on the other hand producers and sales agents believe the bottom is nearly reached. Buying is slow in the Philadelphia market and producers are looking for orders. Demand at Baltimore is light. Contract making is considerably behind the average and there is little stocking up to this time. Interest is centered in the export situation as it affects Baltimore.

In the Birmingham, Ala. district the steam trade is quiet. Coal is accumulating, but this factor so far has not become a serious problem. Several railroads have closed contracts for their requirements covering the next twelve months and others have our proposals.



Lake Navigation Not in Full Swing Yet



Lake navigation is not expected to open fully until about the middle of May. There is considerable ice in the upper Lakes and although many boats are loaded at Lake Erie ports they will wait for the ice to clear before starting for destinations. During the week ended April 30 soft coal dumped at Lake Erie ports amounted to 365,438 tons of cargo coal and 15,490 tons of fuel coal, making the dumpings to date 1,005,556 tons of cargo coal and 42,384 tons of fuel coal.

Domestic Anthracite Still Moves Rapidly

Domestic sizes of anthracite continue to move rapidly. Independent product is in heavy demand and it is said that many buyers, some from Canada, are canvassing the coal fields. The steam sizes are accumulating. It is reported that one or two producers have made contracts for large tonnages of rice coal on a basis of $1.75 per ton. Heavy shipments of the larger sizes are being made West.

"The rate of production of anthracite in the third week of April was the same as in the second week," the Geological Survey reports. "The total output in the week

ended April 21, including mine fuel, dredge and washery coal, and sales to local trade, is estimated at 2,065,000 net tons. The cumulative output during the present calendar year to April 21 stands at 31,602,000 net tons, an increase of 9,804,000 tons, or 45 per cent, over the production in the corresponding period of 1922."

Beehive Coke Output Gains

Production of beehive coke increased during the third week of April, according to the Geological Survey, to 437,000 net tons, as compared with 421,000 net tons the previous week. The cumulative production of beehive coke during 1923 to April 21 amounts to 5,995,000 tons as compared with 2,217,000 tons in the corresponding period of 1922 and 2,277,400 tons in 1921.

Anthracite Miners Call Off Button Strike

A strike of 10,000 anthracite mine workers at the Pennsylvania Coal Co. mines in the Pittston district was called off Monday, April 30, when mine foremen at a meeting with the general grievance committee, agreed to see that the thirty-five men who refused to join the union at the Butler colliery, which caused the suspension, get into good standing with the organization. The walkout was not sanctioned by the district officers of the union.

Work was resumed Tuesday, May 1.

Foreign Market And Export News

British Coal Mines Yield Record Output; No Let-Up in Demand

A new high record in production was attained by Great Britain's mines during the week of April 14, when 5,777,000 tons of coal was produced, according to a cable to *Coal Age*. This is the record output for this year and also surpassed the output for any week of 1922, 5,742,000 tons having been produced during the week ended Dec. 16. The output for the week of April 7 was 3,941,000 tons.

Demand was irregular last week and quotations showed a slight decrease from the previous week.

According to a newspaper dispatch, South America has bought 100,000 tons of Monmouthshire large coal for delivery over the last half of this year on a basis of about 30s per ton at the mine.

Although most of the miners have returned to work following the recent labor troubles, and production increased, there has been no slackening in demand for Welsh coal. It is estimated the Welsh mines lost at least a fifth of their April production of the best steam coals and were compelled to carry their arrears of delivery into May.

Both contracts and inquiries from the Continent are steady and show no indication to fall off.

Coal exports officially reported from London for the week ended April 27, in tons follow:

South Wales district	2,300
Newcastle (Tyne) district	11,214

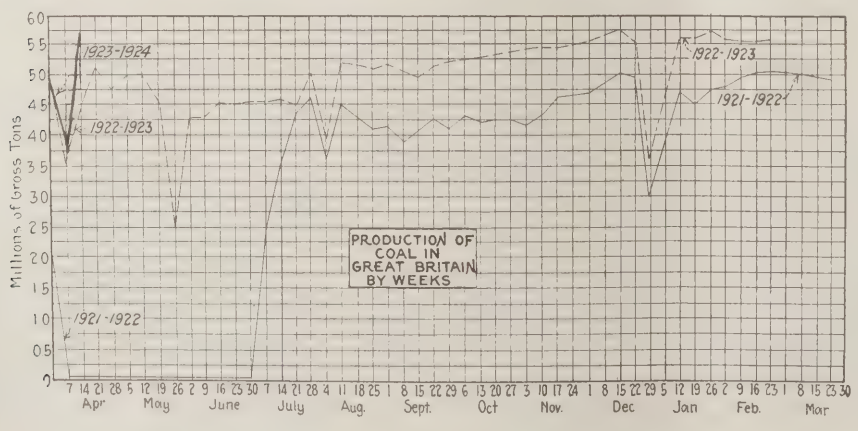
Board of Trade statistics showing coal exports during March of this year, compared with the same month of last year, in tons, follow:

	March 1923	March 1922
Germany	1,836,000	468,000
France	1,805,000	1,238,000
Italy	788,000	681,000
Argentine	184,000	132,000
Other countries	2,567,000	2,682,000
Total	7,180,000	5,201,000

Dumpings at Hampton Roads Decrease

Business at Hampton Roads was not so brisk last week, but large supplies of coal were in transit and accumulations at the piers substantial. The week ended with few vessels in sight, although the trade had a generally bright outlook.

The seamen's strike had not affected business at that port, and no fear was held by shippers of developments that would interfere with business. The general feeling was that the strike would not work any hardship there.



Coastwise trade held firm, while export business was good, with more coal moving to France and still other cargoes for France in sight. Contracts were not in evidence, and little faith in the strength of the market was held.

French Coal Production

During February, coal production in France, in metric tons, was as follows:

Districts:	Coal	Coke	Patent Fuel
Arras (devastated and non-devastated mines of the Department du Pas-de-Calais)	1,035,453	40,949	37,194
Douai (Department du Nord: all devastated mines)	374,384	38,035	75,201
Saint-Etienne (Loire coal field)	265,481	27,827	15,213
Lyons (Bianzy, La Mure, etc.)	227,458	.....	23,143
Clermont-Ferrand (minor coal fields of the center of France)	103,546	.....	9,267
Southern Coal fields: Alais	146,791	583	55,279
Southern Coal fields: Toulouse	152,757	9,463	4,984

Totals	2,478,584	121,682	224,964

Production in January amounted to 3,147,681 tons of coal, 131,994 tons of coke and 292,880 tons of patent fuel. Due to the strike in the Lorraine district coal produced during February was 314,936 tons less than in January and coke 5,033 tons less.

Swiss Coal Imports

During the year 1922 the total imports of coal into Switzerland amounted to 2,200,000 tons, as compared with 1,630,000 tons in the preceding year. Though the imports increased largely in 1922, yet they represented only two-thirds of those before the outbreak of the war. The steadily progressing electrification of the country decreases the demand for coal to a certain extent, the Gotthard line alone using now about 110,000 tons of coal less than before its electrification.

News Items From Field and Trade

ALABAMA

The School of Mines of the College of Engineering of the University of Alabama offers five fellowships in mining and metallurgical research in co-operation with the U. S. Bureau of Mines, open to graduates of universities and engineering schools who have proper qualifications to undertake research investigation. The value of each fellowship is $540 per year of nine months beginning Sept. 1. The following problems have been selected for investigation for the year 1923-1924: (1) Beneficiation of Iron Ores: (a) High Silica Iron Ores. (b) Brown Iron Ores. (c) Gray Iron Ores (Partly magnetic). (2) Coal Washing.

Fellows will be exempt from all laboratory and non-resident fees and will only be required to pay a matriculation fee of $10, student activities fee of $13.50 per year and a diploma fee of $15. Applications are due not later than June 15th and should be addressed to H. D. Pallister, Professor of Mining Engineering, School of Mines, University of Alabama, University, Ala.

ALASKA

B. B. Stewart, supervising mining engineer for Alaska, announces **a big increase in production of coal by private operators** in 1922 on Alaskan public lands. The output last year in the territory amounted to 84,403 tons, as compared with 76,285 tons in 1921, an increase of 8,118 tons. Government operations on reserved units form less than 10 per cent of the total production.

COLORADO

SUMMARY OF COAL PRODUCTION OF COLORADO, 1922

Number of mines operated	275
New and old mines opened	36
Mines closed, 16; abandoned, 2; total	18
Sub-bituminous coal produced, tons	2,814,779
Semi-bituminous coal produced, tons	714,322
Bituminous coal produced, tons	6,441,444
Anthracite coal produced, tons	17,255
Semi-anthracite coal produced, tons	15,810
Total coal produced, tons	10,003,610
Increase, 1922	861,663
Run-of-mine coal produced, tons	3,727,227
Lump coal produced, tons	2,852,582
Nut coal produced, tons	664,832
Pea coal produced, tons	73,115
Slack produced, tons	2,685,854
Percentage of slack produced	42.8—
Coal mined by hand, tons	4,904,874
Coal mined by machine, tons	5,098,736
Kind and number of machines used: Compressed air, 176; electric, 297; total	473
Coal mined for shipment, tons	6,592,881
Coal shipped out of the state, tons	1,887,884
Coal sold to local trade and used by employees, tons	544,611
Coal used at the mines for steam and heat, tons	227,836
Coal made into coke, tons	750,998
Coke made, tons	490,668
Days coke ovens were operated	337.7
Coke ovens used	377
Men employed at coke ovens	173
Miners employed: Pick, 4,824; machine, 3,770; total	8,594
Total men employed in and about mines (average)	13,436
Number of employees, foreign born	6,222
Employees speaking English	12,363
Average days worked (man days)	199.54
Daily production per miner, tons	5.8
Annual production per miner, tons	1,164 +
Number and type of safety lamps used: Flame, 883; electric, 4,906; total	5,739
Carbide lamps used	8,772
Pounds of carbide used (approximately)	213,456
Cost of development work in mines during 1922, 137 mines reporting	$779,202
Days lost account of car shortage, 109 mines reporting	5,619
Coal lost through shortage of labor (37 mines reporting), tons	489,975

ILLINOIS

Mine No. 2 of the Bell & Zoller Coal Co. at Zeigler, was scheduled to reopen April 25 after a two-week's shutdown following **a breakdown of the main hoisting engine.** While hoisting coal about three o'clock in the afternoon, the driving rod of the engine broke and both cylinder heads blew out. Nobody was hurt but the under frame was broken and had to be welded. **A strike of engineers** at about the same time took three men off the job but they were expected to return by the 25th.

Injury to six men and some property damage was done at Mine No. 12 of the Old Ben Coal Corporation recently at Christopher, when the steps in the airshaft of the mine gave way, letting six men fall a short distance to the bottom of the pit. Some of the injured men were engaged in repairing the steps when the accident happened while others were ascending the steps to leave the mine. It is the opinion of Superintendent L. T. Putnam that one of the higher flights of steps gave away and its weight caused the others to fall. The mine will not be operated until the steps and air shaft are repaired.

The mines of the Johnston City Coal Mining Co. at Johnston City **and the Freeman Coal Mining Co.** at Freeman **are to be electrified** according to announcements just made. The mines will also be equipped with electrical machinery and latest methods of mining by electrical equipment. The power for these mines is to be furnished by the Central Illinois Public Service Company, now supplying over 70 mines in Illinois with electrical power.

On Tuesday, April 17, **the No. 55 mine of the Springfield District Coal Mining Co. broke its previous hoisting record** of 2,452 tons, producing 2,602 tons. The mine is in charge of Mine Superintendent Harry Preval and Thomas Lawless, manager. This is considered a good record.

Recently the **No. 9 mine of the Consolidated Coal Co.**, located at Murphysboro, **has been closed down on account of high water** in the Big Muddy River. **The Security Coal & Mining Co.** at DuQuoin was about ready to resume operations after being closed down for four weeks on account of a creek breaking in, when the same creek got on a rampage again and poured in once more.

J. L. Bane and A. E. Butters, both of Ottawa, are interested in **a project to reopen the Rutland coal mine.** Rutland is a village near Ottawa on the Freeport division of the Illinois Central, the old "main line." Mr. Bane is the president of the Ottawa Ice & Fuel Co. and Mr. Butters is an attorney. The two men have offered to put in capital to the amount of $30,000 if Rutland citizens will raise $10,000. A meeting has been held in the village and $4,700 has been raised for the purpose.

Drillers for the Schuline Mining Co. on the Weir farm, near Sparta, **have completed their work,** as the drill has gone through the second vein of coal at a depth of 140 feet. The coal is 5 ft. 10 in. thick with a good roof. As soon as the shaft can be lowered from the first vein to the second vein, the mine will be worked. It was originally the intention to mine the first vein but it was found that this vein was of uneven thickness and could not be mined successfully so a decision was reached to drill to the second vein.

The Chicago Norfolk Western Coal Co., 343 South Dearborn Street, Chicago, has been incorporated with capital of $20,000 by L. C. Sieber, C. B. Sieber and J. L. Johnson.

The Coloma Coal and Lumber Co. of Virden, has been incorporated with capital of $45,000. N. E. Tiedebohl is the president; William H. Hocker, vice-president, and T. C. Tiedebohl, Jr., secretary and treasurer. The officers are the sole directors.

Fred Price, superintendent of the mine of the Tamaroa-Little Muddy Coal Co., at Tamaroa, has resigned on account of ill health caused from injuries received in a mine explosion a few months ago. He has been succeeded by Superintendent Frankey, formerly connected with a Freeburg mine. Two weeks ago the mine was forced to suspend operations for some time due to the caving in of a portion of the shaft. Excessive rains caused the walls of the shaft to give away. The damage has been repaired, however, and the mine is again operating as usual.

INDIANA

The Struggling Monkey mine, operated by Charles Whitlock, of Terre Haute, failed to meet the pay roll of the miners on Tuesday, April 10, regular pay day, and because of this fact the mine **has shut down,** with a possibility that work will not be resumed under the present management. The mine was started by the late Ben R. Whitcomb about six years ago. A deal is at present under way and if the negotiations are completed the plant will be taken over and operated by the Interurban Coal Co., which is now operating mines in Vigo, Clay and Sullivan counties. This company is owned principally by W. A. Satterlee, Henry Meyer and Dr. I. D. White, of Clinton.

IOWA

The new Pershing No. 2 mine will be located two and one-fourth miles north and east of the present location of Pershing No. 1 mine, a 3,000 tonner, making it about five miles from Tracy. The company hopes to be able to hoist 2,000 tons a day from the new shaft by winter. The new mine is to be electrically equipped throughout, drawing power from Des Moines through the Knoxville (Iowa) plant. The No. 1 Pershing mine has had an average of 600 men on the payroll all winter, and plans to have 450 or 500 men in the new works by next autumn.

The Summit Coal Co. of Nevada, is making arrangements to open a mine near that town.

KANSAS

Governor Davis has sent Edward T. Hackney, formerly a member of the state board of administration, **into the Kansas coal fields in response to the petition of many union locals urging the state government to do something to keep the coal mines working.** Mr. Hackney began by going over the Jackson-Walker Coal Co.'s books in Kansas City, Mo. Then he proceeded into the field. From there he went home to Wellington without making public the nature of his forthcoming report to the Governor. All the union petitions for state action against mine closings asked that under no conditions should the matter be turned over to the Kansas Industrial Court, so thoroughly detested by union labor and so bitterly assailed by Governor Davis during his campaign for election last autumn. Governor Davis has announced, however, that the case of shutdown mines may be referred to the court anyway. **Union officials of District 14** have answered many inquiries from members saying the organization **will not approve any co-operative mine leases for miners who want to try running mines.**

A mule fell on **Harry McGoey,** an employee of the Clemens Coal Co., in the company's No. 18 mine Feb. 15. The man died on April 14. His widow and son were awarded $3,118 in the District Court at Pittsburg.

J. F. Klaner, of the Klaner Coal Co. of Pittsburg, left April 17 for Kodiak, Alaska. After three weeks of bear hunting there, Mr. Klaner intends to go to Whale Island, where he is part owner of a blue fox farm, staked and stocked by him and a partner a little more than a year ago.

KENTUCKY

Bids for coal for the seven state penal and charitable institutions of Kentucky will be received until May 8, according to an announcement by B. T. Brewer, secretary of the State Board of Charities and Corrections. Announcement of the successful bidders will be made May 10. The seven institutions last year used approximately 37,000 tons of coal, ranging in price from

$1.55 to $5 the ton. No contracts were made last year on account of the coal and railroad strikes.

MINNESOTA

The Pure Carbon Co., Wellsville, N. Y., recently appointed as its Minneapolis representative, the **Charles A. Etem Co.**, 917-A Marquette Avenue.

MISSOURI

The sale of all stock in the Jackson-Walker companies of Kansas City, Mo., held by Mrs. L. C. Jackson, of Wichita, Kan., and Mrs. George T. Walker, of Kansas City, to C. P. A. Clough, president of the five companies, has been announced. The transfer gives Mr. Clough 49 per cent of the stock of the Jackson-Walker Coal & Mining Co., with capital stock of $150,000; all stock of the Marceline Coal & Mining Co., Marceline, Mo., capital stock $80,000; 50 per cent of the stock of the Toluca Coal Co., Toluca, Ill., capital stock $125,000; complete control of the Jackson-Walker Mercantile Co., Frontenac, Kan., capital stock $50,000, and of the Marceline Mercantile & Supply Co., Marceline, Mo., capital stock $20,000. J. A. Parkinson, secretary-treasurer of the companies, is the only other stockholder. He holds 51 per cent of the Jackson-Walker Coal & Mining Co. stock and 50 per cent of that of the Toluca Coal Co.

James F. Walsh and others have chartered the **Donald Coal Mines** for coal production in the vicinity of Westernport, the capitalization being $250,000.

T. H. Walton, head of a large coal company in Higbee, reports that **it is possible that his mine will have to close down for the summer** at least, unless he can obtain a renewal of the contract with the Chicago & Alton R.R., which expired April 1. Walton has been in Chicago, where he has been conferring with officials of the road relative to a new contract. The mine is one of the largest in this section of the state. There is practically no demand for commercial coal from local mines because of Illinois competition.

The mine of the **Marriott Coal Co.** in Moberly **has been reopened** following a 10-day shutdown. A new wage scale has been made.

NEW HAMPSHIRE

On April 19 the House rushed through a bill patterned after the Massachusetts law, giving authority to state and local boards of trade and sealers of weights and measures **to inspect all coal coming into the state and to condemn and confiscate all coal unfit for ordinary use.** Dealers are prohibited from selling coal with any foreign substance which impairs the quality. Fines from $100 to $1,000 and imprisonment from one month to one year are provided.

NEW YORK

The Coal & Iron National Bank has elected as vice-president **John M. Ross,** who for the past 18 months has been vice-president of the Lowry Bank & Trust Co., of Georgia.

OHIO

The Cincinnati School Board will open bids for approximately 30,000 tons of coal for the supply of its institutions on May 24.

Considerable development work is going on in various coal fields of the state of Ohio judging from the number of corporations chartered with the Secretary of State. Among the number are the **Nelsonville Consolidated Coal Co.,** of Nelsonville, with a capital of $25,000, chartered by D. H. Armstrong, R. S. Oxley, D. F. Shafer, A. H. Schory and A. P. Amann; **the Blowers Coal Co.,** of Bellaire, with a capital of $200,000 to mine coal in the eastern Ohio field by George A. Blowers, M. M. Weinstein, C. H. Poole, A. E. Clark and D. B. Brooks; **the Empire Mining Co.,** of Shawnee, with a capital of $12,000 by George W. Morgan, W. C. Edwards, John E. Nealson, E. B. Hopkins and William R. James; **the Standard Clay Co.,** of Empire, with a capital of $100,000 to mine coal among other things by Frank W. Stone, M. G. Bell, C. G. Jones, George S. Cotrell, and R. B. Holmes.

The Magnolia Coal Co., Magnolia, has been incorporated with a capital of $5,000 to mine and deal in coal both at wholesale and retail. Incorporators are H. E. Hunker, Paul G. Weber, Anne Zimmerman, Frank T. Bow and Agnes Parker.

Jerome Watson, St. Clairsville, Ohio, has been **appointed chief of the Ohio division of mine inspectors,** succeeding William Robinett, of Jacksonville. Mr. Watson formerly held the same position under the last administration of Governor James M. Cox.

Three large mines of the Ohio Collieries Co., near Athens, **were closed recently** for an indefinite period, and it was later announced that more of the big coal operators in the Hocking Valley field would suspend operations soon unless conditions in the fuel trade show marked improvement. The closing of the mines was due to a slump in trade brought on by the weather and the late opening of the lake trade.

I. H. Buchanan, general manager for the **Clay County Coal Co.** at Patchfork and the **Willis Harlan Coal Co.,** at Hima, Ky., was in Cincinnati recently purchasing new equipment.

PENNSYLVANIA

Several of the small coal-mining companies in the Connellsville region which last year signed the union scale of wages upon the condition that the union would keep them supplied with men, have **refused to renew the agreement this year.** The coal business being very unsatisfactory as to demand and prices a number of these operations have closed down indefinitely.

The Hudson Coal Co., the second largest anthracite taxpayer in the state, has carried **an appeal from the Auditor General's assessment** to the Dauphin County Court. The Philadelphia & Reading Coal & Iron Co., **has appealed to the State Supreme Court** from the Dauphin court's decision involving a half million tax.

The Burns bill, providing that mining and distribution of coal be placed under the jurisdiction of the Public Service Commission and that all coal-carrying and coal-producing corporations be subjected to the supervision of the commission as public utilities, **was defeated** in the House April 24 by a vote of 55 to 110. There was no debate on the bill. Representative Burns did not even explain its provisions to the House. Representative Whiteman, of Westmoreland, who opposed the measure in committee, merely stated to the House that it proposed to put all coal corporations in the state under the Public Service Commission.

A preliminary injunction has been granted in the court at Ebensburg, Cambria County, **the Sterling Coal Co.,** against E. P. Reed and Robert Reed, trading as the Reed Coal Co. at Bakerton, Cambria County. The injunction is to restrain the defendant company from mining coal in West Carroll township, the plaintiff company claiming ownership of the "B" seam, comprising some 85 acres, and that the defendant company has no right in or upon the tracts mentioned in the bill and would interfere with the plaintiff's operations.

Stanley Guoga, of Wilkes-Barre, pleading guilty April 25 before Judge Fuller on the charge of violating the mine act of June 2, 1891, **in smoking a cigarette in the mines** of the Lehigh & Wilkes-Barre Coal Co., **was fined $200** and sentenced to serve one month in the county jail. Sentence was suspended, and the defendant was paroled on condition that he pay the costs and $100 into court for charitable purposes. The money must be paid within 60 days.

Judge John A. Berkey of Somerset County on April 26 granted **a preliminary injunction** on a bill of equity filed by the Quemahoning Coal Co. **to restrain union officials from any procedures such as congregating, picketing, etc.** The defendants named are John Brophy, individually, and as president of District No. 2, U. M. W. of A., and others, including all the officers of District No. 2, and organizers employed by them. May 4 has been fixed for the time of hearing at the court house in Somerset. It is alleged in the bill that the defendants have been interfering with the company's operations at the mines at Harrison.

The Central Cambria Coal Mining Institute held a meeting in Portage on April 25 and **elected the following executive board:** Wallace Sherbine, general manager of the Portage-Wilmore Coal Co.; Patrick J. Keenan, Plymouth Coal Mining Co.; James West, Sonman Shaft Coal Mining Co.; F. M. Fahey, of the Gorge Coal Mining Co., and S. R. Kellerman, of the Sonman Shaft Coal Mining Co.

The Sugar Notch Colliery of the Lehigh & Wilkes-Barre Coal Co. was **shut down April 9 by the refusal of a miner to accept other work** when it had become dangerous for him to continue the employment on which he was engaged. He refused to work anywhere else in the mine. The aggrieved miner arrived at the mouth of the shaft with a member of the Grievance Committee, stopped the inside men from going to their labor and prevailed upon the breaker employees to go home. The colliery was unable to operate, 816 men being forced into idleness. The loss of production is about 1,800 tons daily.

The Hazle Brook colliery of the Wentz Coal Co. has resumed operations after being idle ten days. The excavation of coal from strippings near the breaker was conducted with such speed that the work of taking off the top layer of clay and rock could not keep pace and the miners had to lay off while the steam shovels caught up with the task of making the anthracite measures accessible.

The report of the **Pennsylvania Coal & Coke Corporation** and subsidiaries for the first three months of 1923 shows **gross earnings of $2,351,348.71,** with operating expenses and taxes, not including federal taxes, of $1,946,592.82. Miscellaneous income amounted to $36,048.97. The net income before federal taxes for the quarter, after deducting charges to income of $51,323.58, was $389,481.28. Tonnage shipped during the three months was 616,375 tons. James A. Hamilton, president of the W. F. Gilbert Co.; of New Haven, Conn., and Edward H. Everett were elected directors of the corporation to succeed R. H. Williams, Sr., and R. J. Doherty, resigned. The annual meeting will be held on May 7.

The Shade Coal Mining Corporation, which is the operating company for the Emerson & Morgan Coal Mining Corporation, of No. 1 Broadway, New York City, **has taken over the Antoinette Mine** of the Frauenheim-Logansport Coal Co., located on the Western Maryland R.R. in Somerset County, and production will commence at once. The coal is a smithing and byproduct fuel and is classified in Pool 9.

Charles F. Hall has resigned his position with the Equipment Corporation of America and **has organized and controls the Acme Equipment Co.,** contractors and dealers in railroad and mining machinery, 207 Fulton Building, Pittsburgh.

The Philadelphia & Reading Coal & Iron Co. has awarded a contract to the Ball Lumber Co. for the construction of ten additional blocks, making twenty houses, at Branchdale. Work has already begun. This makes a total of **seventy-two new houses either building or about to be built** in the Reading's spring program. Ground is now being prepared for the 18-house operation at the Bast colliery, at Big Mine Run, near Ashland. These houses will be in an unusually good situation on a hillside commanding an extensive view of the Mahanoy Valley, and the village seems certain to become one of the showplaces in that district. It will be known as Woodside, its site being on what was formerly known as Woodside Park.

The following bituminous coal companies were chartered at Harrisburg recently; **Meadow Brook Fuel Co.,** mining coal and manufacturing coal, Uniontown; capital stock, $20,000; Thomas M. Whyel, Uniontown, treasurer; incorporators, Thomas M. Whyel, Elizabeth P. Whyel and Frances P. Hutchison, Uniontown. **Douglass Brothers Coal Co.,** R. F. D. 3, Beaver Falls; $10,000; producing, mining and selling coal; treasurer, E. T. Douglass, who with David Douglass, R. F. D. 3, Beaver Falls, and H. A. Douglass, New Brighton, is an incorporator.

State Senator Robert D. Heaton, Schuylkill County, **introduced two bills** in the Senate April 24 **amending the workmen's compensation act** of 1915. One of these continues compensation in case of remarriage, and the other provides that the first day of disability shall be included as one of the ten days during which no compensation shall be paid and that the computation of the 300-week period in cases of death shall start with the day after death except where the death occurs within the ten-day period after an accident, in which case compensation shall be paid beginning the tenth day after the accident.

A state charter was issued recently to the **Cohen Mitchell Coal Co.,** Lewistown, Hyman J. Cohen, Lewistown, is treasurer, and the capital stock is $100,000. The incorporators are Hyman J. Cohen, Harold D. Cohen and James W. Mitchell, Lewistown.

The following bituminous coal companies have recently been incorporated: **Superior Coke Co.,** Latrobe, $100,000, Joseph M. Steele, Latrobe, treasurer. Incorporators, C. A. McFeely, Pittsburgh; F. B. McFeely, Latrobe and Frank O. Keltz, Latrobe. **H. A. Davis & Co.,** Pittsburgh, $500,000; D. R. Davis, Pittsburgh. Incorporators: H. A. Davis, H. R. Davis and H. B. Day, Pittsburgh, **Anderson Fuel Corporation,** Pittsburgh, $25,000; Guy D. Anderson, Aspinwall. Incorporators: Guy D. Anderson, Aspinwall; Bruce Harrison, Aspinwall, and Raymond B. Gabler, Pittsburgh.

A. W. Bittner has been appointed by the Consolidation Coal Co. as referee in all disputes arising between employees of the company at its mines in Somerset County.

TENNESSEE

O. P. Pile, Chief Mine Inspector, **will hold an examination for mine foremen** at the Government Building in Knoxville, May 22, 23 and 24.

VIRGINIA

The Virginia Coal & Coke Co. reports for the first quarter of 1923 net earnings of $243,559 after payment of interest, taxes etc. This is equivalent, after preferred dividends, to $1.81 a share earned on $10,000,000 outstanding common stock. While less than the net earnings of $273,184, or $2.10 a share, in the preceding quarter, it is a striking increase over the corresponding period of 1922, when the company returned a net loss of $81,047. The gross earnings for the first three months of 1923 were $351,752.

At the annual meeting of the **Mead-Toliver Coal Co.** a resolution was passed **to change the name of the company to the Killarney Smokeless Coal Co., Inc.** The principal office to be in the Peoples Bank Building, Lynchburg. The company was formerly under the management of C. H. Mead, Beckley, W. Va., but the present officers are as follows: James Gorman, president and treasurer; Dr. J. H. Craft, vice-president; G. H. Nowlin, Jr., secretary. The directors of the company are James Gorman, John J. Morrison, G. H. Nowlin, Jr., Philip Konrad, George W. Craft, Dr. J. H. Craft and J. A. Morrison.

WEST VIRGINIA

The Bertha Coal Co., Pittsburgh, Pa., **plans extensive improvement and enlargement of its Frances Mine, at Cresaps,** near Moundsville, on the Ohio River division of the Baltimore & Ohio RR. Approximately $300,000 will be expended for the erection of a new rail and river tipple, thus insuring steady operation of this plant, since at the present time shipment is being made by rail only. Modern shaker-screen equipment of the latest type as well as the erection of a number of new houses is included in the expenditure. The Frances Mine is now producing about 1,000 tons of coal daily, which will be increased to 2,500 tons when these improvements are completed.

Beckley people have organized the **Raleigh Peerless Coal Co.** with a view to developing coal properties in the Winding Gulf region, the new concern being capitalized at $100,000. The office of the company will be at Beckley. Among those interested are G. E. Thompson, Bernadine Norris, W. W. Goldsmith, H. M. Kilgore, and W. G. McClure.

C. H. Mead and associates have organized the **Faith Pocahontas Coal Co.,** Mr. Mead having been elected president. This company will at once proceed to develop its large holdings in the near future, several thousand acres of smokeless coal land on Milam Fork Branch of the Virginian Ry. being owned. Unless there are some unforeseen delays it is believed that it will be possible to begin shipping coal before the end of the year.

The West Virginia Rail Co., Huntington, purposes spending $290,000 to add another unit to its plant to manufacture frogs, switches, steel mine ties and timbers.

The Blake-Towson Coal Co. has been organized by Kingwood people with a view to operating in the Preston County field, having a capital stock of $125,000. Offices of the company are to be at Tunnelton. Chiefly interested in the new enterprise are G. C. Blake and Edith D. Blake of Cumberland, Md.; M. P. Blake, of Tunnelton, and Nora A. Towson of Kingwood.

Walter R. Thurmond and others prominent in the mining industry of Logan have **launched the Perry Branch Coal Co.,** the headquarters of which are to be at Kleencoal. The company has a capital stock of $25,000. Associated with Mr. Thurmond in the new company are W. L. Harvey, of Kleencoal; Innis D. Thurmond and R. J. Sellman, of Logan.

The Brighton Coal Co. has been launched by J. M. G. Brown and others of Morgantown, with a capital stock of $150,000. Mr. Brown and some of his associates recently purchased the holdings of the American Gas Coal Company at a sale decreed by the circuit court of Monongalia. Interested in the new company are: J. M. G. Brown, Robert D. Hennen, Louise R. Hennen, Mary B. Brown and T. Frank Burk.

The report of special commissioners Frank Cox, James R. Moreland and Edward G. Donley having been submitted and confirmed, **sale of the property of the American Gas Coal Co.** for $301,600 to J. M. G. Brown and Robert G. Hennen, under a decree of the court, has been confirmed.

The Island Creek Coal Co. reports operating profits of $990,656 for the first quarter of 1923, against $1,021,627 in the corresponding period last year. After allowing for depreciation and depletion reserves and estimated federal taxes there was reported net earnings available for dividends of $738,276, against $760,496 in the first three months of 1922.

With a view to operating in the Harrison County mining region, **the Evert Coal Co. has been organized,** having a capital stock of $25,000. Offices of the company are at Clarksburg. Active in organizing this concern were D. H. Dent, of Pickens; E. M. Pearcy, K. G. Davis, J. A. Farrell and O. L. Karichoff, all of Clarksburg.

Coal production in 1922 in the Pocahontas field, which totaled 15,073,908 tons, according to figures compiled by the Pocahontas Operators' Association, was the third highest in the history of the field. In 1916 there was produced in and shipped from the field 16,171,782 and in the following year a total of 15,156,353. In 1921 only 12,184,390 tons were shipped. Since the opening of the Pocahontas field in 1883 a total of 268,863,716 gross tons of coal have been shipped.

An injunction granted New River operators some time ago will remain in force until either the operators or the United Mine Workers seek to have it changed, and in either event **six months notice is to be given by the party seeking to change the status of the injunction.** That in substance is the gist of an agreement reached between counsel representing the McKell Coal & Coke Co., the Jones and other interests in the New River field and the United Mine Workers of America. An order to this effect has been filed with the clerk of the District Court for the southern district of West Virginia. Judge McClintic issued the injunction last summer, an appeal being taken by the United Mine Workers to the U. S. Circuit Court of Appeals. The agreement of counsel on each side—C. J. VanFleet for the United Mine Workers, and J. W. Maxwell for the operators—will apply to the appeal in the court of appeals and the case will be continued from term to term until either one side or the other seeks a change, provision having been made that in such an event, the six months notice will be required as has been agreed upon for the lower court.

WISCONSIN

Emil J. Earling, president of the Central Coal Co. of Milwaukee, announces that the **company has sold its coal docks in Milwaukee and at Escanaba, Mich.,** to the Industrial Coal Co., of Pittsburgh. The Central Coal Co. will in the future, Mr. Earling says, confine its activities to the operation of its mines in Illinois and the sale of rail coal. The company has operated its docks in Milwaukee for eighteen years.

Emphatic denial of the reported consolidation of the C. Reiss coal interests with the Pittsburgh Coal Co.'s dock holdings throughout the Northwest has been entered by various persons in both companies, notably Peter Reiss, who was recently made a director of the Pittsburgh Coal Co. He said he had been interested in the Pittsburgh company for years and his election as a director to fill a vacancy had no significance. Northwest officials of the Pittsburgh company also deny the story, saying that although a consolidation was considered at one time, there is no likelihood of it now.

WASHINGTON, D. C.

The use of industrial motion pictures has reached a point where the Secretary of the Interior believes a more **uniform policy should be adopted in the preparation of such films.** The various bureaus of the department heretofore have proceeded separately without regard to a common policy. There has been some criticism of government films on the ground that they give undue advertising to certain companies. A thorough investigation of the whole subject is being made with the idea of establishing a policy and with the idea of materially expanding the production of this type of motion picture.

A request that American coal producers submit bids in connection with a purchase of 150,000 tons of coal which the Central Railway of Brazil expects to make on May 19 has been received at the U. S. Department of Commerce.

The Bureau of Supplies and Accounts of the **Navy Department, will open bids** at noon on May 10 for furnishing and delivering about **22,450 gross tons of various sizes of anthracite** at various points along the Atlantic coast and Great Lakes, Ill. Detailed information may be obtained at the office of the bureau.

CANADA

At the recent annual convention in Toronto of the **Canadian Retail Coal Dealers' Association** interest was manifest in the possibilities of Alberta coal for Ontario, but it was the general feeling of the merchants that they would have to move warily for the present, until the probable lower cost at the mines, the prospect of lower freight rates and the qualities of the different kinds of coal had been more fully investigated. It was felt by most of the delegates that the Government commissions for the supply of coal for domestic use had so far been a waste of public money and the government is to be asked to discontinue the appointment of these so-called useless bodies. G. F. Rogers, of St. Catherines, Ont., was elected president: W. H. Smith, Owen Sound Ont., vice-president, and B. A. Campbell, Brantford, Ont., secretary-treasurer.

COAL OUTPUT OF BRITISH COLUMBIA, MARCH, 1923

VANCOUVER ISLAND DISTRICT

Mine	Tons
Canadian Collieries (D) Ltd.,

Canadian mines during December last produced 1,734,000 net tons of coal, making the output for the calendar year 15,045,000 tons, or 2 per cent below the three-year average of 15,307,800 tons, according to a statement issued by the Dominion Bureau of Statistics. **Imports** of coal for December **amounted to 2,307,000 tons,** or 471,000 tons less than in the preceding month but 67 per cent more than the three-year average for the month. For the calendar year imports were 14,255,600 tons, while the three-year average for the same period was 18,634,000 tons. A slight decrease in exports of Canadian coal was recorded, **166,200 tons being exported during the month** as compared with 169,000 tons in November, a decrease of 2 per cent. The record for the year 1922 equalled 82 per cent of the three-year average. There was available for consumption in Canada during December 3,875,000 tons, which when compared with the three-year average for the month was 40 per cent greater. The coal available for consumption in Canada during the year was 27,482,300 tons as compared with a three-year average of 31,736,800 tons, a decrease of 14 per cent.

Coal Mines of British Columbia used 26,762,001 ft. of timber, including 12,279,871 ft. of mine props and 10,740,000 ft. of butts, last year.

Coke made from bituminous coal as a substitute for United States anthracite was under discussion in the Senate Committee on Fuel Supply for Canada when C. B. Bagg, of the Montreal Heat & Power Co., stated that his company had marketed up to 150,000 tons of domestic gas coke a year. The coke output was limited to the quantity of gas which could be used, so that it was not practicable to encourage more people to use coke.

Members of the Western Canada Coal Operators' Association in session at Calgary passed a **resolution against the proposed amendments to the Industrial Disputes Act** that would mean, in brief, **consideration of the arbitration board's report before wages could either be reduced or increased.**

Publications Received

Production of Explosives in the United States During the Calendar Year 1921, by Wm. W. Adams, Bureau of Mines, Washington, D. C. Technical paper 313. Pp. 25; 6 x 9 in.; tables.

An Investigation of the Properties of Chilled Iron Car Wheels, by J. M. Snodgrass and F. H. Guldner, Engineering Experiment Station, University of Illinois, Urbana, Ill. Part III. Bulletin No. 135. Pp. 100; 6 x 9 in.; illustrated. Covers strains due to brake application, coefficient of friction and brake-shoe wear.

Mine Power, by W. R. Woolrich, University of Tennessee, Engineering Experiment Station, Knoxville, Tenn. Bulletin No. 2. Pp. 49; 6 x 9 in.; illustrated. Factors in the economical generation, distribution and maintenance of electric power and power equipment in the coal mines of Tennessee and Kentucky are the subjects touched upon in this bulletin.

"Howdy" is the name of a little bulletin which has recently made its appearance. It is published monthly by The Morrison & Risman Co., Inc., of Buffalo, N. Y., and a copy may be had by dropping a postcard to them. It is devoted to fun and facts.

Cage Partition Plate for Crushers. Wm. M. Davidson, St. Louis, Mo., assignor to the Williams Patent Crusher & Pulverizer Co., St. Louis, Mo.; 1,439,872. Dec. 26, 1922. Filed Sept. 11, 1922; serial No. 587,433.

Miners' Knife. Henry Kallio, Painsdale, Mich.; 1,440,014. Dec. 26, 1922. Filed April 5, 1920; serial No. 371,350.

Obituary

Frederick Marietta, formerly a mine superintendent of the Stickel & Frank coal interests at Connellsville, Pa., died April 17. He was a graduate of the Carnegie Institute of Technology in Pittsburgh in the co-operative department of mining engineering, and also received a diploma from the U. S. Bureau of Mines in first-aid and mine-rescue work. During the recent war he was assigned to the Wissahickon Barracks at Cape May.

Traffic News

The Smokeless Fuel Co. takes exception to a tentative report involving numerous shipments between the company's mines and Lamberts Point, in which certain demurrage charges were approved. The company contends that the demurrage charges are in excess of those that would have accrued had the railroads released from demurrage account cars which had been dumped prior to the registry of their respective vessels. The Norfolk & Western contends that the tariff and not the exchange rules is the basis for the assessment of demurrage charges. The record will not support a finding, the carrier contends, that the computation of detention by subtracting the date of car arrival from the date of release of equivalent tonnage, without allowing any additional credit for the days elapsing between the date of dumping and the subsequent date of arrival of equivalent cars in transit, is unjust and unreasonable, or contrary to the applicable tariff.

Freight rates on coal from northern Alberta mines to Prince Rupert **have been raised $1 per ton,** according to notices sent out by the Canadian National Railways.

In a complaint filed by the Winding Gulf Colliery Co., the Interstate Commerce Commission is asked **to require the Chesapeake & Ohio Ry. and the Virginian Ry. to interchange at Pemberton** and not discriminate in the rates applied upon coal traffic interchanged at that point. The commission is asked to require the railroads to provide other facilities and service and to establish New River district rates on coal traffic interchanged within the district from the complainant's mines.

The Northern West Virginia Coal Operators' Association, in a traffic case against the Pennsylvania R.R., points out that in July, August, September and October, of 1919, mines on the Monongahela Ry. had an average car supply of 81.9 per cent. During December, January and February, following, the average supply was 54.6 per cent. On the other hand, it was declared that mines on the Pittsburgh & Lake Erie and on the Monongahela division and Pittsburgh West End Division of the Pennsylvania, received 90.5 per cent car supply during the first period and 60.5 per cent during the second period. Had cars been distributed on a pro-rata basis, the mines operated by members of the Northern West Virginia Coal Operators Association would have received an average of 87 per cent car supply. For that reason it is contended that mines on the Monongahela were subjected during those periods to prejudicial action and are entitled to reparation.

Increases in the rates on coke from the Cleveland ovens to points in New York State, which the Wheeling & Lake Erie R.R. proposed to put into effect May 1, **were suspended** April 26 by the Interstate Commerce Commission until Aug. 29, to allow investigation. The present rate on coke to all of the northern New York territory from Cleveland is $2.39 per ton, the commission order said, while the suspended Wheeling & Lake Erie schedule proposed to make new rates to Niagara Falls at $2.76 per ton, to Lockport $3.40 and to North Tonawanda $3.19.

Questions involved in the case of the **Northern West Virginia Coal Operators' Association vs. the Pennsylvania R.R.** will be considered at an Interstate Commerce Commission hearing in Washington on May 15. Examiner McQuillan will preside.

Rates on bituminous coal from southern Illinois fields to Ste. Genevieve and Mosher, Mo., have been unreasonable since March 26, 1921, in the opinion of examiner Koch expressed in a tentative decision. Reasonable rates are suggested for the future and reparation should be paid, the examiner holds.

In the case of the Big Mandy Coal & Mining Co., the Interstate Commerce Commission holds that **the rates on coal from mines on the Lenox R.R. to Cincinnati and points in the Cincinnati switching district, as well as to points in Central territory, are unreasonable.** Reparation was awarded and reasonable rates prescribed for the future.

Thomas Moore, purchasing agent of the Virginian Ry., is authority for the statement that **orders for equipment** for that road placed since Jan. 1 **aggregate $6,000,000.** On April 12 the company ordered 1,000 all-steel gondola cars having a capacity of 120 tons and 500 all-steel hopper coal cars of a capacity of 70 tons. In January the road ordered 15 freight locomotives.

The Hood Coal Co., Wilmar Coal Co., Cava Coal Co. and Mack Coal Co.., operating in the vicinity of Shinnston, W. Va., have filed a petition with the Interstate Commerce Commission asking reopening of their case with a view to **placing them on the same rate basis as enjoyed by other companies in the field.** The petition states that "a comparison of rates shows that the complainants' mines are well within the distance limits of the group taking the Fairmont rate to Eastern and Western destinations.

Coming Meetings

The American Wholesale Coal Association will hold its annual convention June 12 and 13 at the Gibson Hotel, Cincinnati, Ohio. Secretary, G. H. Merryweather, Union Fuel Bldg., Chicago, Ill.

Illinois and Wisconsin Retail Coal Dealers' Association will hold its annual meeting June 12-14 at Delavan, Wisconsin. Secretary, I. L. Runyan, Great Northern Building, Chicago, Ill.

Southwestern Interstate Coal Operators' Association will hold its annual meeting June 12 at Kansas City, Mo. General Commissioner, W. L. A. Johnson, Kansas City, Mo.

Pennsylvania Retail Coal Merchants' Association will hold its annual meeting May 23 and 24 at Wilmington, Del. Secretary, W. M. Bertolet, Reading, Pa.

American Association of Mechanical Engineers will hold its spring meeting at Montreal, Quebec, Canada, May 28-31. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

National Association of Purchasing Agents will hold its eighth annual convention and Informashow at Cleveland, Ohio, May 15-18. Convention headquarters, room 219, Hotel Winton, Cleveland.

The National Association of Manufacturers will hold its 27th annual convention at the Waldorf-Astoria, New York City, May 14-16.

New England Coal Dealers' Association will hold its annual meeting at Providence, R. I., June 13-15. Secretary, C. R. Elder, Boston, Mass.

National Retail Coal Merchants' Association will hold its sixth annual convention June 25, 26 and 27 at Scranton, Pa., with headquarters at the Hotel Casey.

National Safety Council will hold its twelfth annual safety convention at the Buffalo Statler Hotel, Buffalo, N. Y., Oct. 1-5. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

International First-Aid and Mine-Rescue meet will be held Aug. 27-29, at Salt Lake City, Utah.

American Institute of Electrical Engineers will hold its annual convention June 25-29, at Swampscott, Mass. Secretary F. L. Hutchinson, 29 West 39th St., New York City.

International Railway Fuel Association will hold its spring convention at the Hotel Winton, Cleveland, Ohio, May 21-24, Secretary-treasurer, J. G. Crawford, Chicago.

The American Mining Congress will hold its twenty-sixth annual convention in conjunction with the **National Exposition of Mines and Mining Equipment,** Sept. 24-29, at the Milwaukee Auditorium, Milwaukee, Wis. Secretary, J. F. Callbreath, Washington, D. C.

American Society for Testing Materials will hold its annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, N. J., beginning June 25 and continuing throughout the week. Secretary, E. Marburg, Philadelphia, Pa.

The Colorado & New Mexico Coal Operators' Association will hold its annual meeting June 20 at Denver, Col. Secretary, F. O. Sandstrom, Denver, Col.

The Electric Power Club's annual meeting will be held at the Homestead, Hot Springs, Va., June 11-14. Executive secretary, S. N. Clarkson, Cleveland, Ohio.

The eleventh annual meeting of the Chamber of Commerce of the United States will be held in New York City May 7-10.

National Coal Association will hold its sixth annual convention June 19-22 at Atlantic City, N. J. Assistant secretary, C. C. Crowe, Washington, D. C.

Michigan-Ohio-Indiana Coal Association will hold its annual convention at the Hotel Sinton, Cincinnati, Ohio, May 22-24. Secretary, B. F. Nigh, Brunson Bldg., Columbus, Ohio.

West Virginia Coal Mining Institute has tentatively set June 5 and 6 for its annual meeting, to be held at Clarksburg, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

Retail Coal Dealers' Association of Texas will hold its eighteenth annual convention at Galveston, June 11 and 12. Secretary, C. R. Goldmann, Dallas.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 23 NEW YORK, MAY 10, 1923 Number 19

Industrial Co-operation—How?

INDUSTRIAL co-operation is a fine sounding phrase but as a phrase it needs considerable interpretation. Under the auspices of the American Mining Congress, a committee endeavoring to give point to the subject held a meeting in New York recently, attended largely by employers of labor. The substance of its deliberations are contained in a formal resolution which, after asserting that industrial peace is vital and can be reached only through mutual confidence between management and workers and that energy should be diverted from strife to practical co-operation, offers the good offices of the Mining Congress toward reaching those desirable ends. The thinking behind this offer to help bring peace in the industrial world is found in two paragraphs of the platform of the Division of Industrial Co-operation of the congress, one stating that the confidence in management so fundamental to industrial peace can be obtained only by closer personal touch between management and employees, the other that "future peace of industry will not be found in 'organized employers' and 'organized employees' that are created to fight each other. This has been tried for half a century and failed."

One can read nothing less from these words than a declaration for the open shop, for each company or plant management to negotiate with its own labor without interference from national organizations of either employers or employees. Thus and thus only is that desired degree of personal contact attained and retained. The open shop, with works councils and employee representation in management has been attained in many places. It is a proved fact in a number of industries, for it withstood the shock of the great boom of 1920 and the depression of 1921. But it is not to be found in the coal industry.

Before the coal operators chase this mirage let them give heed to the practical problem in the immediate forefront, of dealing with a miners' union that is today, because of its national scope, in as strong a position to dictate terms to management as were the coal operators to dictate to labor thirty years ago. The movement for a mine workers' union was fostered by the necessities of the worker. History is quite clear on that point. Of more immediate interest than discussion of a theory of industrial co-operation based on abolition of the union is the question of whether the employers of union coal-mine labor can recognize and cope with the condition of a labor monopoly essentially complete now. The country is not complacent in the matter; it is quiescent because it has turned the job over to a coal commission. If all that the coal operators can suggest by way of solution for national strikes is to smash the union they may expect instead paternalistic control. No matter what a commission might urge, no congress will deal in such stern doses.

Is present necessity about to drive the union operators into collective action, or into the hands of the government? The non-union operators, observing the two major disasters that have overtaken their Northern brethren in recent years, are united in steadfast opposition to the union, fighting fire with fire to save themselves from domination by Indianapolis.

"Maximum Economic Strength"

IN A RECENT issue of the *United Mine Workers Journal*, Philip Murray, vice-president of that organization, made a plea since repeated to the U. S. Coal Commission for the unionization of all the coal-mine workers of the country, in which article he says "All the coal operators in the country, including those in the non-union fields, are organized in a single, compact national organization known as the National Coal Association." From this he argues that "in all fairness, it should be possible for all the miners of the country" to have their nationwide union so that they "may meet the maximum economic strength of the operators with the maximum economic strength of the mine workers."

Mr. Murray's statement of fact is on a par with that of the man who defined a lobster as a red fish that walked backward. A lobster is not a fish, it is not red, and does not walk backward. The National Coal Association is national in name but not in membership; it includes in its membership but about half of the bituminous coal operators and none of the anthracite operators. It is not organized for and has never functioned as a body for negotiating with the labor it employs. And when it comes to matching "full economic strength" the mine workers, with some two-thirds of the soft-coal and all the anthracite mine labor, have demonstrated most conclusively that they now have a united whole and that the operators, and the whole country, are as shifting sands before them.

The largest employer of non-union coal-mine labor, the Steel Corporation, does not participate in the National Coal Association. There are many others, both union and non-union, that are outside the fold. Mr. Murray doubtless would tell the operators that they too should enjoy the check-off and thereby make their association 100 per cent strong. He appreciates, of course, that were it not for the compulsory payment of dues to the United Mine Workers through the check-off, the paid-in membership of that organization would be nearer one-half than all the men in a given field. The record in the anthracite region shows this. Just as there are operators who are willing to participate in the benefits of organization but who are not willing to share in the responsibility and expense, so there are mine workers who pay dues and go along with the crowd only because they are forced to do so by the complete control of the union in their field.

There is no organization in the bituminous-coal industry that brings the operators together for the purpose of bargaining with union labor. Locally in smaller

groups the associations of operators have interest in labor as the chief factor for their existence, now that trade bureaus have been banned, but on a national scale there is no counterpart for the local wage-negotiating group. That is one of the serious lacks in the industry. Instead of arguing for a national labor union, for the inclusion of non-union fields within its grasp, the United Mine Workers might strive to organize the coal operators in order that there might be some semblance of equality in the economic strength of the two groups. It is all one-sided now.

The strike of 1922 is too fresh in memory for anyone to entertain even a small measure of credence for Mr. Murray's naïve assertion that the poor weak United Mine Workers should be left unhampered by the non-union coal operators in its efforts to build itself to that measure of "full economic strength" whereby it may meet the "maximum economic strength" of the operators. He certainly must have smiled when he penned those words.

If Flour Were Coal

CENSUS returns show that the value of the products of flour and grist mills in the United States in 1921 was nearly $1,200,000,000. The number of establishments engaged in the industry that year was 6,485. Thus it will be seen that in point of value and of number of plants the milling industry is comparable with that of the production of bituminous coal. The decline in value of output from 1919 to 1921 was 42 per cent, compared with less than 9 per cent drop in the output by soft-coal mines in the same two years.

In other words, here is an industry about which little is heard, one that comes in for no berating by the public, one that has as great fluctuations, as great irregularity in operation, as bituminous coal. Flour is as essential to public welfare, health and happiness as coal, perhaps more so in that all the flour is used for human consumption and but from 10 to 15 per cent of bituminous coal goes to householders. The Census reports also that the unit values of flour and grist-mill products were much higher in 1919, were in fact abnormal, as a result of federal stimulation of production during the war. Yet there has been no long series of congressional investigations or a Flour Commission. It is to be presumed that the operators of flour mills are just as human as coal men, with a normal desire to be engaged in a profitable business.

What are the conditions that have immunized flour? In the first place there is no United Flour Workers of America, hence no stoppage of flour production. Should 75 per cent of the flour mills be closed for five months because of a disagreement between the management and the men, a situation would arise demanding the attention of the federal government. Although flour can be more easily stocked than coal, the country normally carries a reserve of less than 30 days' supply. Should the production of flour be stopped for even a short period, prices most certainly would mount and actual want develop. But that has never happened.

In the last three years the production of wheat flour has ranged from 7,461,000 barrels to 13,917,000 barrels per month, a spread as wide as is found in the production of coal, save during national strikes. Yet the flour mills have had no occasion to complain of car shortage. The output of the mills apparently flows over the rails as regularly as it is produced and required. If flour were to have the experience of bituminous coal there would be periods when customers could get but half the quantities they required or bought because the railroads were not able to furnish transportation.

Now, since the men who make and market flour are as numerous as those who produce soft coal, and since they are business men, large and small, as in the coal industry, there must be problems of production and of merchandising, cancellations of orders, questions of contract performance, of quality, and of price, such as characterize the coal trade. It is hardly to be thought that the flour industry functions perfectly. May it not be that because it has no major labor problem and no difficult transportation situations flour is not like coal?

Concerning Private Management of Roads

FREIGHT-CAR shortages, as reported by the American Railway Association, are gradually decreasing. At the same time loadings of freight cars are increasing, and at approximately a million cars per week are now at a level previously reached only in the fall season, when crop and coal movements are accelerated. In the week of April 21 loadings of revenue freight were 957,743 cars, exceeding all weeks since that of Nov. 17, 1922, and within 6 per cent of the highest record of all time, that of the week of Oct. 15, 1920.

Now, the conjunction of these two things, car loadings of such huge proportions and a shortage currently less than 50,000 cars and diminishing, means one of two things—either the roads are vastly more efficient than in the immediate past, when car shortages of over 100,000 cars were coupled with loadings below 800,000 cars per week, or there has been an increase in equipment and facilities. The answer is found in both directions. A total of 5,130 new freight cars and 142 new locomotives were put in service in the first half of April. In the three and a half months from Jan. 1 to April 15 the number of new cars installed reached 44,302 and of new locomotives 1,077. On April 15 new cars on order numbered 116,890 and locomotives numbered 1,950.

These additions to equipment do not suffice to account for the remarkable showing being made by the railroads; they are but substantial helps. The railroads are digging in their toes and working to meet the load imposed by a truly remarkable increase in industrial activity. They have a definite program. They are organized into a definite, compact unit. They have a common motive and that is to show the country that, given half an opportunity, the railroads of the United States can, *under private ownership and management,* meet the transportation requirements of the country.

The railroads have called on the managers of all other business to assist them in carrying out their program for this year by loading cars to capacity, by decreasing car detention and by storing coal during the summer. Business is responding. A part of the railroad managers' program calls for storage of railroad fuel during the coming summer. Reports are to the effect that but few roads have taken steps toward putting down coal against next winter's needs. When they really put the coal storage part of their program in action the railroads will have assured themselves of relief for a major portion of their coal transportation problem of next winter.

Efficiency Methods Practiced at Hardburly Mines

Storage of 480 Tons Aggregate Capacity Steadies Flow of Coal to Tipple—Egg Coal from Two Seams Kept Separate—Entry Driving Speeded with Lowered Cost and Bettered Air—Slate Dumped at Minimum Expense

By Alphonse F. Brosky
Assistant Editor, *Coal Age*, Pittsburgh, Pa.

IN PREVIOUS articles on the methods and practices of southeastern Kentucky it will have been noted that not only is there a wide diversity in the mining methods of the various coal companies but that the surface equipment also is by no means standardized. For instance, many different means are used for lowering coal to the tipple, the rope-and-button conveyor, the scraper conveyor, tubes and the monitor being all in use. The last of these is found at the Hardburly mine of the Hardy-Burlingham Mining Co., located at Hardburly, Perry County, Ky., which village is six miles northeast of Hazard.

The 2,500 acres of land owned by this company is underlaid by three minable coal seams. No. 4 seam is 100 ft. below the railroad and has a thickness of 39 in. No doubt this coal will be removed in the distant future after the thicker and more easily mined coals above it have been extracted. No. 7 seam is 200 ft. above the railroad, its thickness being almost 5 ft. From this the greater part of the output of the mine is derived. No. 8 seam also has been mined. This is 68 in. thick in some inextensive areas. It lies approximately 380 ft. above the railroad. At the time of my visit no coal was coming from this upper seam.

As the coal comes to the twin tipple at the bottom from two different hills, whenever both seams are being worked, four dumphouses are kept in operation. After being transported a short distance along the hillside from the mine openings the coal is discharged by kickback dumps into 100-ton bins. This operation requires the services of four men in each of the upper dumphouses and six men in each of the lower dumphouses. The coal is lowered to the tipple in 10-ton tank-type monitors, two in balance for each dumphouse.

The company contemplates a change in its method of lowering coal to the tipple. The use of monitors breaks the product, for when they are used it has to be dumped twice instead of once. To avoid this loss, the coal on both sides of the valley, hereafter will be transported in full trips from both seams to one point at the elevation of No. 7 seam, from which it will be lowered to the tipple in mine cars on an endless rope operating on an 18-per-cent grade. With the proposed change a full trip of mine cars may be fed to the bottom, and their contents emptied by a rotary dump into a large storage bin. At this point a reciprocating feeder will deliver the coal to a conveyor which will carry it to the shaker screens.

At the present time only one bed, the lower, or No. 7, seam is mined, though, as already mentioned, the upper, or No. 8, seam is provided with equipment for lowering coal to the tipple. Here, as elsewhere, the railroad-car supply is limited and the mine operates only a few days a week. Rather than work two seams part time and only at a fraction of capacity, the company closed down the upper seam and takes coal only from the lower, or No. 7, seam. To avoid confusion the conveying and dumping problems will be described on the assumption that both seams are being mined.

The monitors handling the two coals separately discharge them at the foot of the hills into individual 20-ton bins. Conveyor feeders discharge the coal to main run-of-mine conveyors of the double-compartment apron type, each of which is capable of handling 300 tons of coal per hour. The two screening units can handle efficiently all the coal that can be passed over the two conveyors, or a total of 4,800 tons per day. This is the ultimate output of the Hardburly mine, which places it in the group of the few large one-tipple operations in Kentucky.

From a distance the dumphouses, because of their generous proportions, closely resemble the usual 1,000-ton tipple and undoubtedly would be taken for such were they located at the foot of the hills. With a view to obtaining a large ultimate output and in order to

NOTE—Headpiece shows Hardburly tipple designed to handle 4,800 tons per day. On the right are two of the dumphouses with the 100-ton bins and their monitor roads. Five tracks go under the tipple.

FIG. 1

Hardburly, Ky.

Largest operation in the Hazard field. Note the four dumphouses, two on each hillside, each receiving the output from a separate seam of coal and each dumping into a separate pair of monitors. All four dumphouses have each a storage capacity of 100 tons. Most of the residences in the mining village are for the housing of two families. Hardburly lies near the headwaters of Lotts Creek not far from the Knott County line but still in Perry County.

insure facility in handling this tonnage the dumping operations in the several headhouses must be practically continuous. Delays at these points would militate against the establishment of a capacity run and cause delays all along the line.

To avoid such irregularities in the flow of coal provision is made at the dumphouses so that coal can be stored in bins in case the monitors are delayed. Thus, if the inclined planes are not working, the operation of the mine continues, at least for a while, unaffected. On the other hand, if the trips fail to come to the dump the supply of coal in the bins allows the monitors to make several trips, thus keeping the tipple in operation. These four bins have inclined bottoms which discharge the coal by gravity to the monitors. At the foot of each hill are located two 20-ton bins into which the monitors discharge. Run-of-mine conveyors feed the coal from these pockets to the tipple proper.

With storage bins thus located the efficiency of the tipple is increased and the tonnage of the mine augmented. The four bins already described and shown in the diagrammatic plan, Fig. 2, each have a capacity of 20 tons, thus providing a total storage of 80 tons, which is available for preparation over the tipple the moment the machinery is started up. At many mines where coal has to be lowered to the tipple much valuable time is lost every morning before the preparation machinery can begin to operate. But at this mine, with the four bins filled, the tipple may run at capacity for a period of eight minutes. This time is sufficient for the loading, lowering and dumping of the monitors, by which the bottom bins can be replenished.

Each of the four dumphouse bins is of 100 tons capacity. They also form reservoirs, and when filled they supply the monitors with coal sufficient to run the tipple at capacity for a period of 40 minutes without needing refilling. These bins release about 150 mine cars which otherwise would have to stand at the dumphouse or on an underground sidetrack all night in order to supply coal for the early morning run.

Two sizes, lump and egg, are prepared over the tipple, the slack resulting being chuted into the railroad car directly from the screens or else carried by a slack conveyor to a mixing table where combinations of various sizes are made. The screening equipment prepares the mine-run coal so that 40 per cent of it, which is known as "lump," passes over a 4-in. round screen, 30 per cent, termed "egg," passes over a 1¼-in. round screen, the remaining 30 per cent, as slack, passing through the latter.

The run-of-mine conveyor,

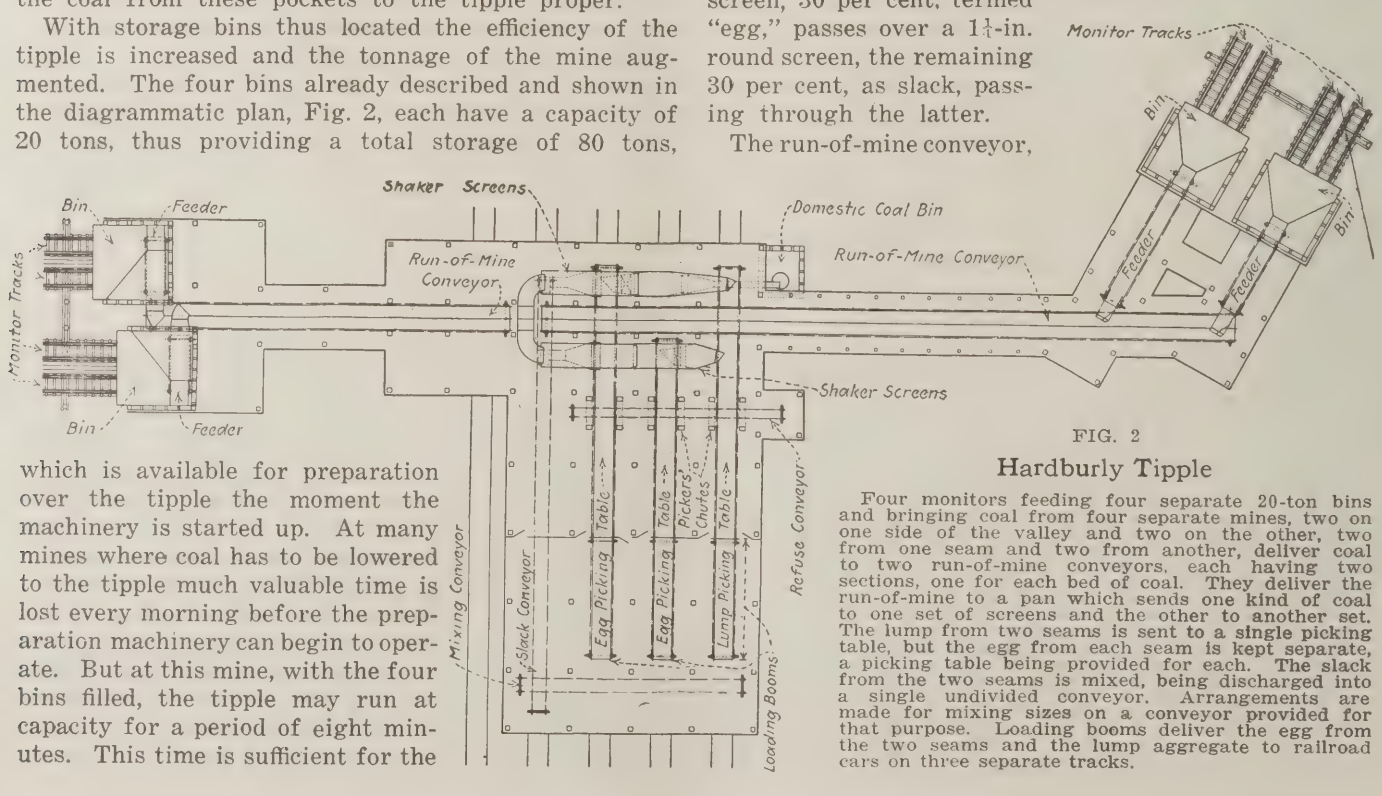

FIG. 2

Hardburly Tipple

Four monitors feeding four separate 20-ton bins and bringing coal from four separate mines, two on one side of the valley and two on the other, two from one seam and two from another, deliver coal to two run-of-mine conveyors, each having two sections, one for each bed of coal. They deliver the run-of-mine to a pan which sends one kind of coal to one set of screens and the other to another set. The lump from two seams is sent to a single picking table, but the egg from each seam is kept separate, a picking table being provided for each. The slack from the two seams is mixed, being discharged into a single undivided conveyor. Arrangements are made for mixing sizes on a conveyor provided for that purpose. Loading booms deliver the egg from the two seams and the lump aggregate to railroad cars on three separate tracks.

FIG. 3

Run-of-Mine Conveyor

On each side of the tipple is a conveyor that takes the whole product of two mines, keeping each separate. It will be seen that at the time of taking the photograph from which this illustration was made the coal from only one mine was being transported, the right-hand half of the conveyor being empty. It will be noted that the conveyor shed is open to the weather on both sides.

which leads from the lower bins to the tipple, has two compartments set side by side, the coal from each of the two seams being carried separately to a receiving bin between the two sets of screens. Here the coal from the two seams is still further diverted, each coal going to its own screening rig. The screens and run-of-mine conveyors are normal to the railroad tracks, but the picking tables with their loading booms run parallel thereto.

Lump coal separated over the two screen sets is merged to pass over one picking table, but the egg for each seam is cleaned on a separate table and loaded into railroad cars without mixing. The egg coal, though it comprises only 30 per cent of the whole product, is singled out for this preference because it is to be used for metallurgical purposes and is not destined, like the lump coal, which constitutes 40 per cent of the product, for the domestic market. The egg coal and slack are shipped to the parent corporation, the Andrews Steel Co., of Newport, Ky., where these products are consumed for metallurgical and steam purposes respectively. Fig. 2 shows clearly the general arrangement.

Two systems of mining are used at the Hardburly mine. The older workings are laid out in panels and operated on the system of half advance and half retreat, by driving as many as twenty-four rooms in one direction advancing and as many more in the opposite

FIG. 4

Tipple Floor

In the foreground are the loading booms and behind them the picking tables. The loading boom to the right takes the lump coal and those on the left take egg coal from two separate seams. The boxes for refuse can be seen alongside the picking tables. They discharge onto a conveyor below. The slack conveyor on the extreme left is out of sight. In the rearground are the screens for the coals from each of the two seams, which in sizing are kept separate. The slack, as also the lump, in the two seams is, however, mixed on leaving the screens.

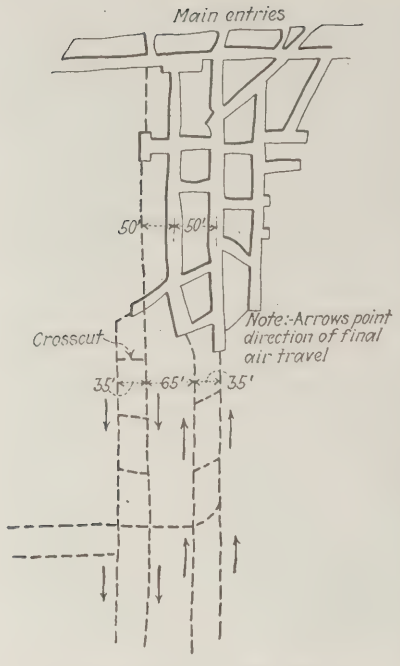

FIG. 5—OLD AND PROJECTED WORKINGS

The old workings at the top have provision made for four headings at 50-ft. centers. Arrangements are now made to make the outer pillars 35 ft. wide less the width of one roadway and to make the inner pillar 65 ft. wide less the same reduction. The two headings will first be ventilated in pairs, one being the return for the other, but after they arrive at a crosshead one pair will serve as returns for the other pair, as the ventilation arrows indicate.

direction retreating, thus completing one panel. The number of rooms for which provision is made, however, depends entirely upon local conditions, being varied as the outcrop is approached. This, however, is the old method, though it, perforce, is being continued in the workings thus started. Unless this system is watched closely, creeps are likely to ensue, and the method described and about to be discarded has the disadvantage that the men in charge, whenever working places are needed, are tempted on the advance to drive rooms in both directions instead of in one only. Another system is now used in the new workings. This is similar to that in operation at the Lynch mine of the United States Steel Corporation. Each section of the mine is divided into six panels.

The rooms in panels Nos. 1 and 2 are driven on the advance end toward the nearer extracted area. The rooms in panels 5 and 6 also are driven on the advance and toward their nearer extracted area, that is in the opposite direction to the rooms in panels Nos. 1 and 2. These rooms are drawn on the advance so as to form straight pillaring lines across panels Nos. 1 and 2 and Nos. 5 and 6. This makes the roadways adjacent to these panels untravelable wherever the pillaring line has struck them, but approach always is possible through the roadway between panels Nos. 3 and 4, which are left standing until the advancing headings reach their terminus; then the roadway between panels Nos. 3 and 4 has served its purpose and is worked out on the retreat. In this way there always is a roadway, well protected,

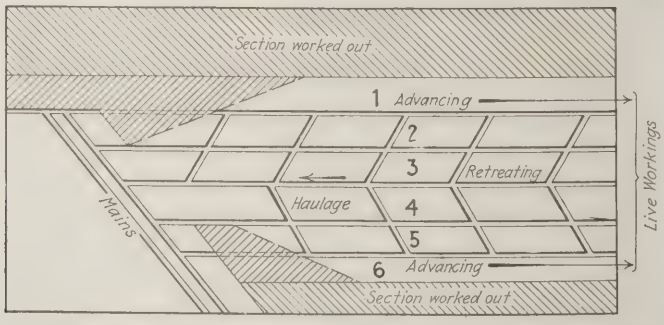

FIG. 6—SYSTEM OF MINING NOW BEING INAUGURATED

Work proceeds, advancing in panels 1, 2 5 and 6 and the pillars are drawn advancing, thus caving the headings so that the roadways would be closed if it were not for the heading between panels 3 and 4 and the side roadways through those panels by which approach is kept open to the working entries. Panels 3 and 4 are withdrawn retreating.

through which access can be obtained to the advancing headings. The rooms are made 350 ft. long. Consequently the pillar on either side of the roadway in the center is of that width and is amply able to prevent any undue pressure such as will close or weaken that roadway.

Barrier pillars 100 ft. wide protect the mains for a distance within the hills until the overburden becomes excessively heavy and then these pillars are widened to 150 ft. The entries were driven at first on 50-ft. centers. Now, however, where the entries are quadruple the three intervening pillars are made of unequal size, the outer pillars of the three being narrowed to 35 ft.

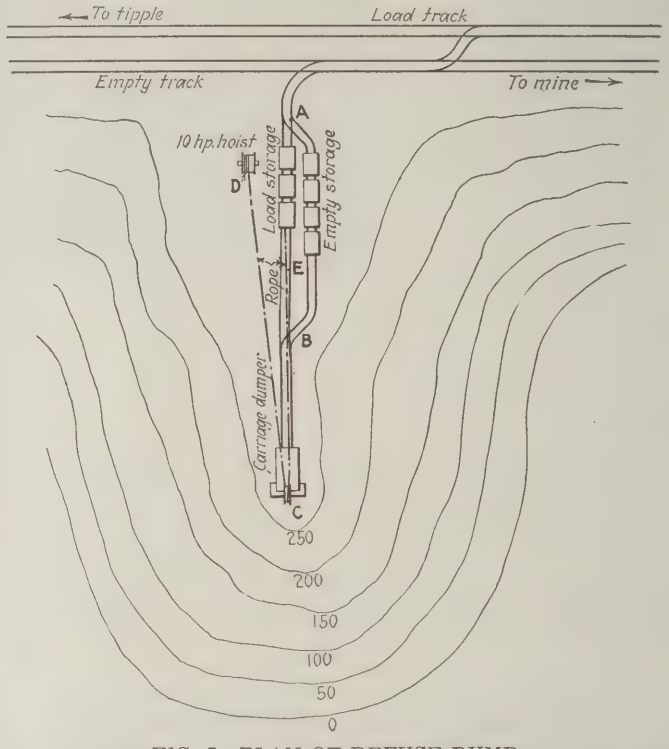

FIG. 7—PLAN OF REFUSE DUMP

A storage for empties is placed from *A* to *B*. At *C* is a carriage dump up which the empties are pulled to a kickback tippling device, *C*, the rope being payed out or wound up by the 10-hp. hoist, *D*. A man is stationed at *E* to transfer the rope from the last empty to the nearest loaded car. The dumping device is automatic, but a man is needed to run the hoist and it is preferable to have one to couple or uncouple the rope.

and the innermost pillar of all being widened to 65 ft. This renders it easy to make crosscuts between the outer pairs of headings and so enables fresh air to be carried more speedily to the advance faces. It also accelerates the progress of the entry. Hardly anything slows up heading driving so much as the excavation of long crosscuts between headings.

Eventually the air is driven up two of the entries on one side and down the two others on the other side, as the arrows indicate in the sketch, but when the headings are being driven temporary brattices are installed on crosscuts, and the narrow pillars are broken through with only two cuts on each side. As the shoveling distance is only a few feet, coal can be shoveled from the crosscut into a car without the formality of laying track. It is unnecessary to make crosscuts through the large pillars more frequently than every 350 or 400 ft.

At the Hardburly property the rock from mines working at an elevation above the railroad is discharged by means of a kickback dump mounted on an inclined track affixed at one end to the rock pile and supported at the other end by a small truck. The arrangement is really that of a track upon a track.

FIG. 8

Carriage Dumper

Two tracks are provided at the end of the dump. One carries the cars on the level, aligns the upper, or inclined, track and supports the carriage by which the upper part of the incline is upheld.

The dumping carriage has been located a stone's throw from the portal of the mine on a slate pile that projects from the hillside. A sidetrack leads off the main tramroad and along the center line of the protruding dump to its brink, where the carriage dumper is placed. The Hardburly mine is equipped with two of these carriage dumpers, one on each hill, which differ in the track arrangement only, the construction of the carriages being identical. Fig. 7 is a schematic sketch showing a track arrangement that will work well with this slate-car dumper.

Between the dumping point and the main tramroad a parting track for empty cars has been placed. The switch, *B*, nearest the carriage dump is a self-acting or spring switch, while that at *A* must be thrown by hand. The mine car loaded with slate is pulled onto the carriage dump by a §-in. steel cable which passes around a horizontal 12-in. sheave, *C*, on the carriage dumper and thence back to a 10-hp. motor-driven hoist located at *D*.

One man can perform the entire dumping operation, but as several daymen generally are working about the mine portal and as the dumping operation is intermittent, two men will work to better advantage, the hoistman and his helper. The latter locates himself in the vicinity of point *E*, where he disengages the rope from the empty and attaches it to the loaded car.

Quick Action with Only Two Men Working

Slate cars coming from the mine singly or in numbers are allowed to accumulate on the slate track until an opportune time when the dumping commences. The loads of slate are pulled by the rope, one at a time, to the carriage dumper, which automatically empties the mine car. The empty car is then kicked back and drops by gravity and switches to the empty or run-around track under control of the friction brake of the hoist.

Little time is consumed in the dumping, as may be realized after a study is made of the general arrangements. But it is only after the slate bank has been built out far enough to afford storage room for empties and loads that automatic and quick action is attained. However, where the hillside falls away sharply, with well-planned stowing of the slate one set-up of the main track, moving successively ahead, should successfully take care of the mine refuse for a period of years, as the larger pieces of slate roll down the hill for considerable distances.

The track bed on any slate dump settles more or less, which necessitates occasional filling in, tamping and aligning of the track. After a time the slate disintegrates and the track becomes compact. Thereafter only the more recent additions to the track approaching the dumping point require attention. A haul of 500 ft. would not be beyond the limits of recognized efficiency.

The empty and loaded track usually are on the same level, for it is easy to get the empty car to pull the rope back to the desired point on the sidetrack. It gets so good an initial start when plunging down the incline of the dumper that it does not readily stop. Nevertheless the distance may eventually become too great, and in that case it will be necessary to grade the

FIG. 9—GALLOWS FRAME

In this view can be seen the rope by which the cars are drawn up the incline, the kickback dump by which the cars are discharged and the device by which the end gate is lifted.

FIG. 10

Another Type of Dumper

Here the track on which the incline rests is not along the line of the incline but at right angles thereto, permitting the dump to be pried sideways and the end of the dump to be fanned out.

empty track so as to keep the car moving to its destination. The friction brake on the hoist can control the mine car at all times.

In Fig. 8 is shown one of these carriage dumpers. The rails on the incline are on a grade of about 20 per cent and are held in gage by bolts of round steel and by spikes in the elevating platform on the right and in a wooden tie in the middle. To this tie are fastened angle-iron guides which hold the riser track on and directly above the level track. If desired, a chain may be fastened about this bearing tie and the track tie beneath it.

The elevating platform has a frame of 4x12-in. oak stringers. These are braced crosswise by bolts and also by a floor of tie members that are alternately 2x10 in. and 3x10 in. The lower end of the frame rests upon 6x8-in. ties which in turn are supported on $\frac{3}{4}$-in. plates. These, by through bolts and plates, are caused to enfold the rails.

The frame rises on a grade of 20 per cent and rests on a six-wheel truck that is built up solid and runs on mine-car wheels. These are chained to the track as shown. A gallows frame, Fig. 9, is erected on the elevating platform and to this is attached the rope sheave and a grab arm for opening the end gate of the mine car. Directly beneath this gallows frame and at the end of the elevating platform is placed an off-balance dumper such as was commonly used in the past for dumping coal.

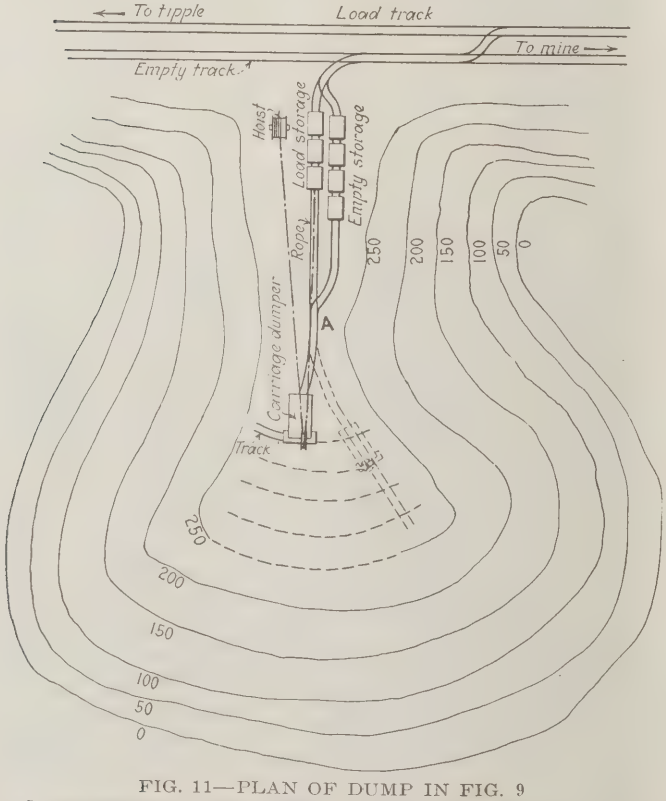

FIG. 11—PLAN OF DUMP IN FIG. 9

In consequence of the ability of the carriage dumper to move on an arc it is possible to swing the dump and enlarge the area over which the refuse is dumped, thus increasing the capacity of the slate pile considerably.

This carriage dump can be moved ahead easily by the hoisting rope, which is passed around a fixed object somewhere in front of the carriage.

Fig. 10 shows another form of the carriage dumper with a track arrangement different from that already described. The wheels of the carriage move on a track at right angles to the line of the incline of the dumper. By moving the incline on these rails the bank is widened out in fan shape. The track can be shifted ahead or pushed over laterally as occasion demands, movement in either direction adding to the storage capacity. Fig. 11 shows a sketch plan of this arrangement.

The men at the Hardburly mine find that by playing a stream of water on the slate dump its settling is hastened, for the water speeds up the rate of disintegration, or weathering, of the slate. The water comes from a 3-in. pump stationed in the mine.

57 Leases Issued to Mine on Public Lands Containing 422,000,000 Tons of Coal

A total of 57 leases for the operation of coal mines on public lands estimated to contain 422,000,000 tons of coal had been issued by the Department of the Interior up to March 1. The required investment of capital in connection with the operation of these leases amounted to $2,976,-650. A total minimum annual production of 2,108,400 tons of coal is required from these leasing operations, technical supervision of which is entrusted to the Bureau of Mines.

The largest number of leases for the operation of coal mines granted in any state was 21, in Utah. Twelve leases had been granted for operations in Colorado, 8 in Wyoming, 7 in North Dakota, 5 in Montana, and 2 each in New Mexico and Washington.

A total of 337 permits for prospecting for coal on leased public lands also were issued by the Interior Department up to March 1. Of these, the largest number, 79, were in Wyoming; 71 were in Colorado, 42 in Montana, 33 in Nevada, 30 in Utah, and 25 in Oregon. Nineteen permits for prospecting in New Mexico have been issued, 18 in Washington, 8 in Idaho, 5 in North Dakota, 3 each in California and South Dakota, and 1 in Arizona.

The coal-prospecting permits issued covered 293,104 acres.

Steep Pitches in Thick Coal Seams Greatly Affect Eastern Middle Anthracite Field Operations

Tendencies in Fifty Years Are Like Those in Other Districts—Thickness Drops 61 per Cent and Production per Man 30 per Cent—Purchased Power Boosts Output

By Dever C. Ashmead
Kingston, Pa.

SMALL basins, steep pitches, thick beds and moderate depths make mining conditions in the Eastern Middle anthracite field different in some respects from those of the Northern field, described in three previous articles in this series. The general tendencies, however, are much the same as the years roll by. The average thickness of the seams in this field has decreased 61.6 per cent, from 21.10 ft. in 1872 to 8.10 ft. in 1922, just as thickness in the whole Northern field has decreased; but this Eastern Middle field still averages 1.27 ft. thicker than the Nanticoke district, 3.22 ft. thicker than Lackawanna and 3.01 ft. thicker than Wilkes-Barre. Output per man in this field, as in the others, also has dropped — from 2.81 tons a day per man fifty years ago to 1.95 tons now — especially since the war, though the output per miner over the half century has fallen much less than in the whole Northern field. The Eastern Middle field comprises the area between the two main deposits of anthracite, the Northern and the Southern coal districts. It is located on a high plateau between these two. In the Eastern Middle district erosion has been very great, so that what remains is only the bottoms of the basins. These take the form of separate canoe-shaped troughs of relatively small size and generally having heavy pitches.

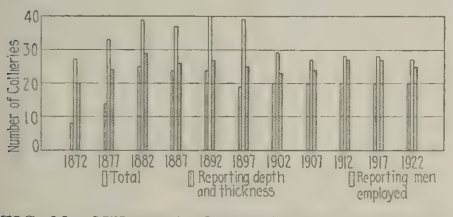

FIG. 38—NUMBER OF EASTERN MIDDLE FIELD COLLIERIES CONSIDERED IN THIS ANALYSIS

This diagram shows in the first column of each group the number of collieries that reported on the thickness of the coal beds and the depth of the workings. The second column shows the number reported by the state mine inspectors, and the last column the number used in the tonnage calculations. The collieries which produced a large portion of their coal from strippings have been omitted from the calculations. However it was not possible to exclude all stripping coal.

The Mammoth bed, known as the Baltimore bed in the Northern field, and the Buck Mountain bed attain great thickness in parts of this field. Small basins, steep pitches, very thick beds and moderate depths are features that make this field radically different from fields previously described in this series of articles. It requires an entirely different type of mining, and in many places permits extensive strippings, especially where thick beds turn over to flats at the outcrop or lie in small basins from which the entire rock filling can profitably be removed to recover the coal. The section shown in Fig. 39 consists of two sections taken from the reports of the second geological survey of Pennsylvania. These sections were about two miles apart but have been combined to show the general conditions in the field. The beds that are being mined in this region, named from the surface down, are as follows: Primrose, Holmes, Mammoth, Wharton, Gamma, Buck Mountain and Alpha. Below these is the Pottsville Conglomerate.

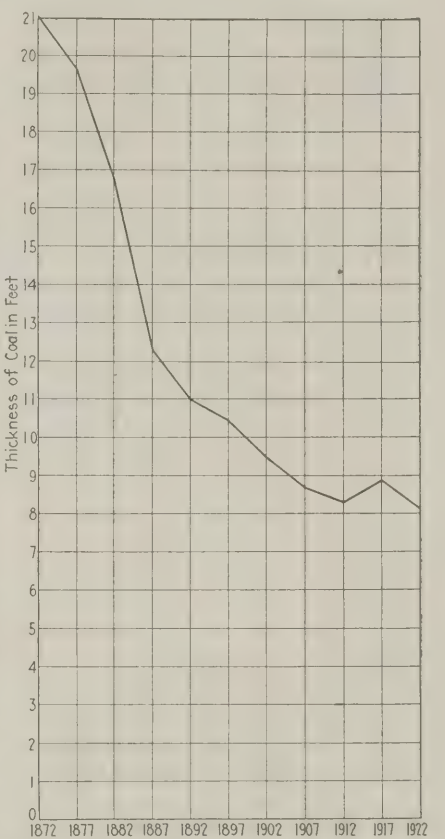

FIG. 40—AVERAGE THICKNESS OF THE COAL BEDS IN THE EASTERN MIDDLE FIELD

In the footnote to Fig. 3 in the study of the Lackawanna district (*Coal Age*, Vol. 23, p. 324) the full method of calculating this curve was set forth. The rapid decrease in the earlier years and the gradual slackening off are of importance as indicative of the future.

In the earlier years of the period under consideration the Mammoth bed was practically the only one that was worked to any extent, but as the workings became more extensive and the first mining approached completion

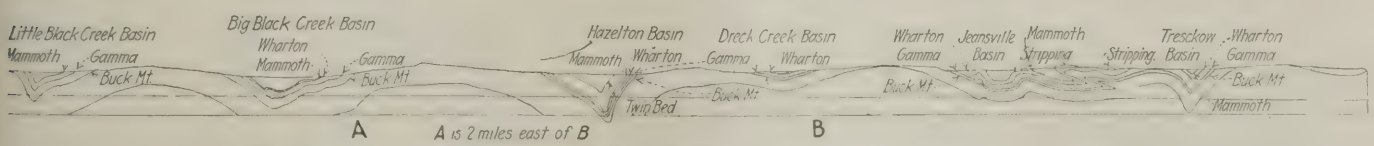

FIG. 39—CROSS-SECTION OF THE EASTERN MIDDLE FIELD NEAR HAZLETON

This cross-section was reproduced from the reports of the second geological survey of Pennsylvania. The northern end of the cross-section was made two miles east of the southern section. This was done so that some idea of the number of different basins in the region might be obtained. It will be noted that the section shows a series of detached V-shaped basins.

NOTE.—This is the fourth in a series of articles by Mr. Ashmead describing conditions in the seven sections of the Pennsylvania anthracite region. Previous articles appeared as follows in *Coal Age*, Feb. 22, March 22 and April 5. The fifth will be printed in an early issue.

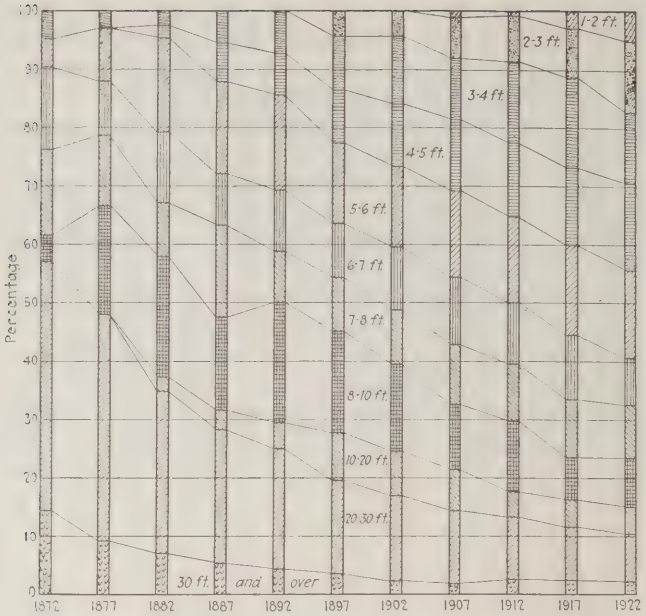

FIG. 41—PERCENTAGE DISTRIBUTION OF BEDS BY THICKNESS IN EASTERN MIDDLE FIELD

in this region, then the thinner beds began to be worked and as a result there has been a steady decrease in the number of thick beds being mined and a corresponding increase in the number of thin beds. Fig. 40 emphasizes this. It shows that the average thickness

TABLE XXXI—NUMBER OF EASTERN MIDDLE FIELD COLLIERIES IN THIS STUDY

	Reported by Inspectors	Having Depth and Thickness Data	Having Tonnage Data
1872	27	8	20
1877	33	14	24
1882	39	25	29
1887	37	24	26
1892	40	24	27
1897	39	19	25
1902	29	20	23
1907	27	20	24
1912	28	20	27
1917	28	20	27
1921-22	27	20	24

of beds decreased from 21.10 ft. in 1872 to 8.10 ft. in 1922. This is a drop of 13 ft., or 61.6 per cent. The decrease, however, has not been uniform, for in the first fifteen years the decrease was 8.86 ft., or at the rate of 0.59 ft. per year, but in the last thirty-five years the decrease has been 4.14 ft., or at the rate of 0.12 ft. per year.

From Fig. 41, which shows the variation in the thickness of the beds being mined, it is seen that in 1872 57 per cent of the beds were over 20 ft. thick and 95 per cent of the beds were thicker than 4 ft. The same condition applies to 1877, except that the beds thicker than 4 ft. had increased to 97 per cent. It was not until 1897 that beds

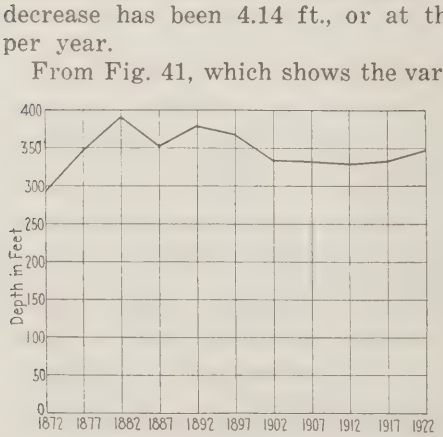

FIG. 42—WEIGHTED AVERAGE DEPTH OF WORKINGS IN THE EASTERN MIDDLE FIELD

Under Fig. 5 in the first part of this article in the footnote is described the method used in the calculation of this curve showing the average depth of workings (*Coal Age*, Vol. 23, p. 325).

TABLE XXXII—WEIGHTED THICKNESS AND DEPTH AVERAGES OF EASTERN MIDDLE FIELD BEDS

	Thickness of Beds	Depth of Workings		Thickness of Beds	Depth of Workings
1872	21.10	284	1902	9.43	334
1877	19.67	346	1907	8.69	332
1882	16.71	391	1912	8.29	327
1887	12.24	351	1917	8.89	333
1892	10.96	379	1922	8.10	347
1897	10.41	367			

less than 3 ft. thick were mined and in 1907 operations began in beds between 1 and 2 ft. thick. In 1922 these amounted to 5.5 per cent of the total number but their proportion of the total coal mined was less than that. In 1922 beds over 20 ft. thick had decreased from 57 per cent in 1872 to only 10.5 per cent, and the beds thicker than 4 ft. had decreased from 95 per cent to 71 per cent. Naturally, thin beds had to be opened in order to keep up production.

Fig. 41 illustrates the even decrease in the percentage of the thicker beds of coal being mined and the correspondingly even increase in thin beds. There seems to have been greater development in the thin beds in this region than in any of the previously described regions, for Fig. 41 shows that in 1922 about 5.5 per cent of the beds were under 2 ft. thick. This may be due to the fact that strippings uncovered both thick and thin beds. Unfortunately the data available do not make this point clear.

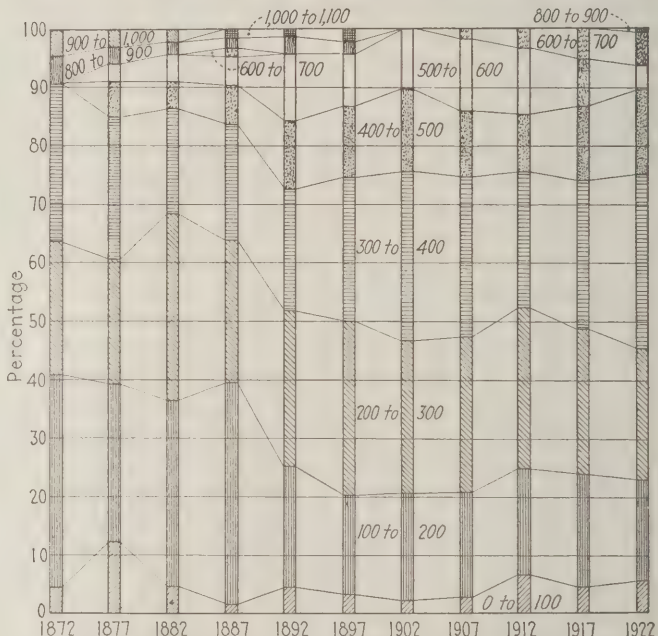

FIG. 43—PERCENTAGE OF BEDS AT EACH 100-FT. INTERVAL OF DEPTH

The method of calculating this curve was described under Fig. 6 in the first part of this article (*Coal Age*, Vol. 23, p. 325).

The average depth of workings in the Eastern Middle field has been affected by the local conditions at one of the operations. As a result the curve in

TABLE XXXIII—POWER INSTALLED AND RELATIVE COAL PRODUCTION

	Boiler Horse Power Installed	Engine Horse Power Installed	Tons per Boiler Horse Power	Tons per Engine Horse Power
1877	25,110	15,085	0.78	1.297
1882	32,670	28,875	0.663	0.749
1887	34,280	.....	0.536	.....
1892	41,550	.....	0.644	.....
1897	39,870	.....	0.741	.....
1902	38,328	33,868	0.683	0.774
1907	62,470	67,493	0.451	0.418
1912	56,210	51,857	0.439	0.476
1917	59,925	46,077	0.444	0.579
1921	49,365	.....	0.510	.....

Fig. 42 does not show the exact conditions as they exist in the field. Generally speaking the depth of the beds is not great, the deepest reported being between the 1,000- and 1,100-ft. intervals, as is shown in the curves in Figs. 43 and 44. The vast majority of workings lie above the 500-ft. interval.

Figs. 43 and 44 show that from 1872 to 1897 there were some rather deep workings in this field. These old workings eventually were abandoned but not exhausted. If they had been omitted from the calculations in the earlier periods, then the curve would have been nearly level, possibly showing a slight increase in depth instead of a decrease. As these deep workings were at a colliery of large production and their depth was weighted with the other depths, their effect on the curve was great. In the earlier period there were two large strippings which since have been practically abandoned. If the data from these operations had been included the depth curve would have shown a decided increase. The easy strippings in this district are becoming exhausted and a growing proportion of the total production is coming from deep mines.

A good many mines in this field have been electrified in recent years with a consequent increase in power consumed. Although steam plants installed in 1921 fell 10,000 b.hp. short of the total installed in 1917, the curve in Fig. 45 indicates an increase in the amount of coal produced per boiler horsepower. Central-station power accounts for this. This same increase in a much less degree is shown in the period from 1912 to 1917. Coal produced per boiler horsepower increased 0.005 ton.

Previous to 1912 the curve shows an almost steady decrease from 1897 and it is reasonable to suppose that this decrease would have continued were it not for the fact that the tendency among coal companies was to forsake mine steam plants for purchased power.

The mule-haulage curve in Fig. 46 shows that the tons of coal hauled per mule steadily declined until 1897. This means that haulage distances were growing. Since then the coal hauled per mule has steadily increased. At first this increase was gradual, then it rose sharply with the introduction of electric locomotives in 1902. Electric haulage probably appeared before 1902, but no inspectors' reports mentioned it until then. From 1917 to 1922 there was a drop in the tons of coal hauled per mule per day.

The locomotive curve shows a continual rise in the number of underground locomotives per 100,000 tons of coal produced. As was to have been expected, the last four years showed a sharp rise in this curve.

The coal lies to a great extent in heavy pitches. Instead of running mine cars into the rooms, they can be loaded by gravity from the breasts in some cases. This restricts the use of the locomotive to main-line

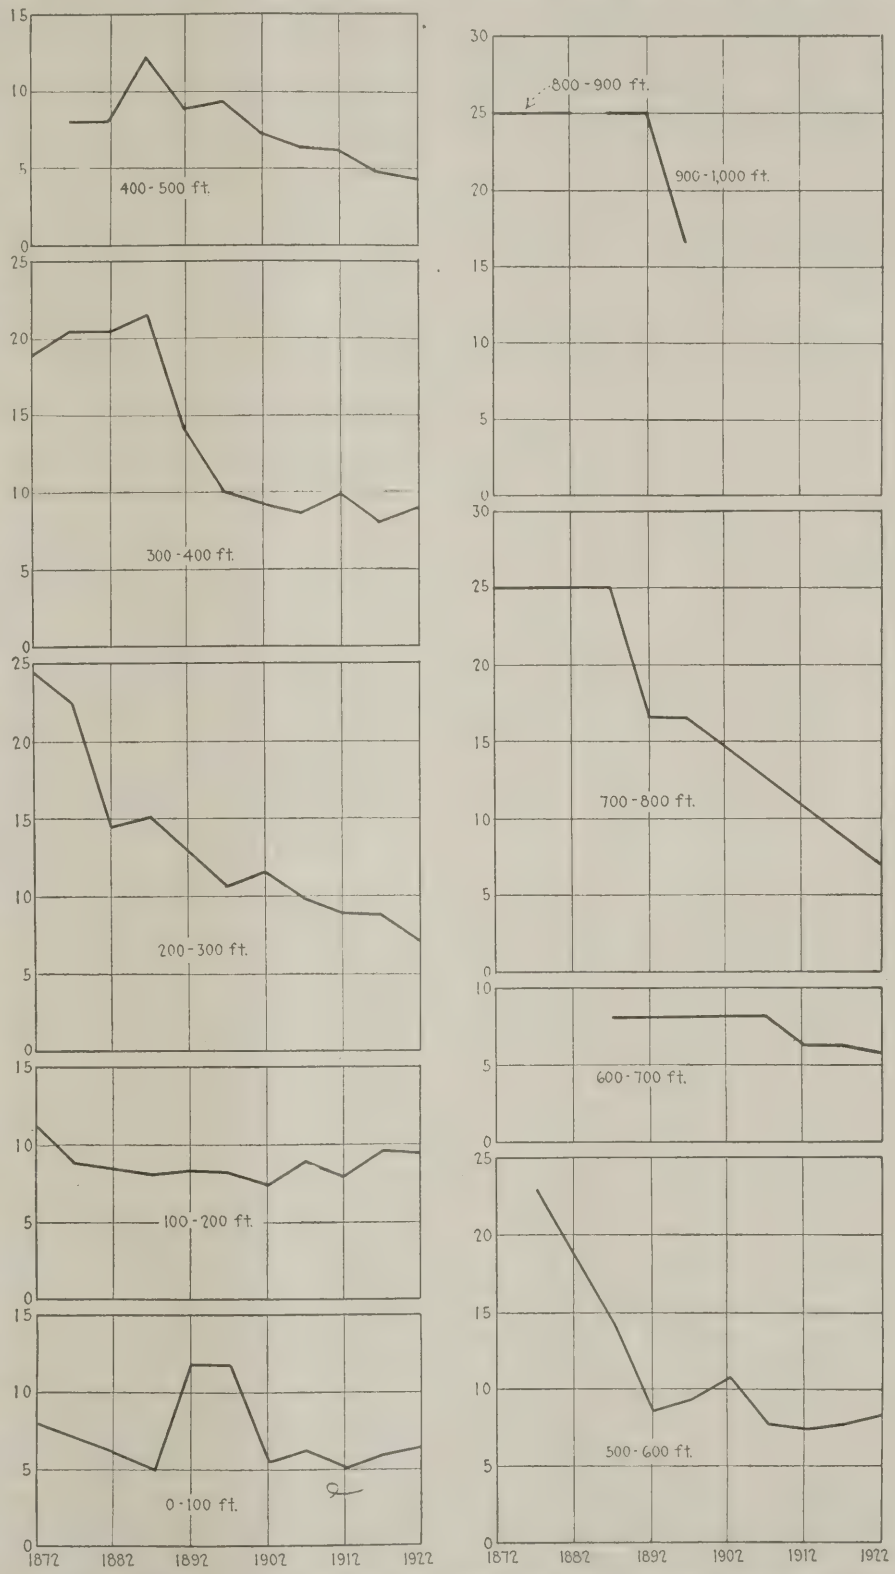

FIG. 44—AVERAGE THICKNESS OF BEDS BY 100-FT. DEPTH INTERVALS

A description of the method used in the calculation of this curve will be found in the footnote to Fig. 7 in Part 1 of this series of articles (*Coal Age*, Vol. 23, p. 326). This is a diagrammatic representation of how the depth of the workings changed and also how the thickness varied at the same time. Here can be seen the influence of a few deep workings on the curve in Fig. 42 during the early period of the operations.

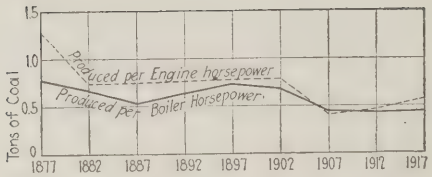

FIG. 45—DAILY PRODUCTION PER BOILER HORSEPOWER AND ENGINE HORSEPOWER

A full description of the method used in calculating this curve will be found under Fig. 8 in Part I of this series (*Coal Age*, Vol. 23, p. 326). Table XXXIII gives some of the important data used in the calculating and the plotting of this curve.

haulage. There is some flat mining in the region, however, and the use of a few locomotives, especially storage-battery locomotives, at certain operations reduces the amount of coal hauled per locomotive.

The general impression of this region is that the length of haul is on the decrease and probably will continue so. Unfortunately it was not possible to obtain exact figures on this.

Most underground mining in the Eastern Middle field is on pitches. Since much coal is loaded into mine cars by gravity, the natural supposition would be that the production per employee would be higher than in the northern districts of the anthracite region. This supposition is borne out in comparison with the Lackawanna and Wilkes-Barre districts, but the four big modern collieries of the Nanticoke district put that territory's production ahead.

TABLE XXXIV—NUMBER OF MULES AND LOCOMOTIVES AND THEIR TONNAGE PERFORMANCE

	Number of Mules	Daily Tonnage per Mule	Number of Locomotives	Locomotives per 100,000 Tons of Output per Year
1877	943	20.77	...	....
1882	1,386	15.10	...	....
1887	1,460	12.56	...	....
1892	1,805	14.59	...	....
1897	1,848	15.96	...	....
1902	1,545	16.92	11	0.14
1907	1,477	19.02	18	0.21
1912	1,096	22.50	39	0.53
1917	1,016	26.22	53	0.66
1921	1,090	23.10	80	1.06

TABLE XXXV—PRODUCTION AND DAYS WORKED IN MIDDLE EASTERN FIELD

	Production	Days Worked		Production	Days Worked
1872	911,771	...	1902	2,758,655	120
1877	2,032,306	194	1907	6,398,023	232
1882	4,949,835	224	1912	6,213,167	233
1887	4,170,708	211	1917	7,030,442	291
1892	4,664,643	226	1921	6,112,997	277
1897	4,608,672	171			

In Fig. 47 the lowest set of curves shows that production per man dropped sharply in the first two periods, more slowly in the next three, ascended in the following three, when strippings and deep mines began to feed coal to the same breakers, but the figure decreased in the final two periods. Production has dropped from 2.81 tons in 1877 to 1.95 tons in 1921, or a decrease of 30.6 per cent.

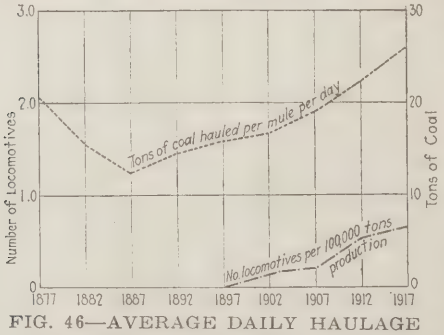

FIG. 46—AVERAGE DAILY HAULAGE PER MULE AND THE NUMBER OF UNDERGROUND LOCOMOTIVES PER 100,000 TONS PRODUCED PER YEAR

In Table XXXIV will be found the data relating to these curves. The method used in calculating them will be found under Fig. 9 in the first article of this series (*Coal Age*, Vol. 23, p. 327).

TABLE XXXVI—AVERAGE DAILY PRODUCTION PER EMPLOYEE IN MIDDLE EASTERN FIELD

	Total Employed			Inside Men			Outside Men		
	Reported	Corrected for Sizes	Corrected for Time	Reported	Corrected for Sizes	Corrected for Time	Reported	Corrected for Sizes	Corrected for Time
1877	2.38	3.20	2.81	4.02	5.40	5.08	5.90	7.92	6.34
1882	2.16	2.87	2.48	3.71	4.93	4.54	5.13	6.82	5.46
1887	1.76	2.13	1.84	3.64	3.67	3.36	4.19	5.06	4.05
1892	1.72	2.05	1.77	3.07	3.65	3.36	3.99	4.74	3.80
1897	1.92	2.20	1.90	3.25	3.73	3.42	4.62	5.31	4.25
1902	1.80	1.90	1.68	2.94	3.10	2.88	4.65	4.92	4.37
1907	1.92	1.99	1.84	3.02	3.12	2.99	5.28	5.47	4.87
1912	2.13	2.16	2.02	3.14	3.20	3.06	6.60	6.72	5.90
1913	2.03	2.07	1.93	3.06	3.12	2.98	6.12	6.23	5.54
1917	2.07	2.07	2.07	3.25	3.25	3.25	5.68	5.68	5.68
1921	1.95	1.95	1.95	2.98	2.98	2.98	5.61	5.61	5.61

The middle set of curves in Fig. 47 indicates a 43-per cent decrease in output per day per inside employee. From the dot and dash line, illustrating the final corrections for both sizes of coal and the change in time it is found that there has been a steady decrease in the output per inside man employed from 1877 to 1902 and then an increase to 1917 and another drop to 1921. The total decrease was from 5.08 tons in 1877 to 2.08 tons in 1921. It is probable that the inclusion of stripping coal here again accounts for the increased production from 1902 to 1917. In spite of the whole period's decrease, the production per inside man is about 20 per cent higher than in the Lackawanna, Wilkes-Barre and Nanticoke districts. The upper part of Fig. 47 indicates the output per outside employee. This curve shows what might have been expected to happen in a period when such progress was made in the preparation of coal. In the earlier years there was a steady falling off in production, due to a reduction of efficiency and to the necessity for better preparation of coal by the addition of more pickers, since there was no mechanical means for cleaning coal in those days. Naturally production per man dropped.

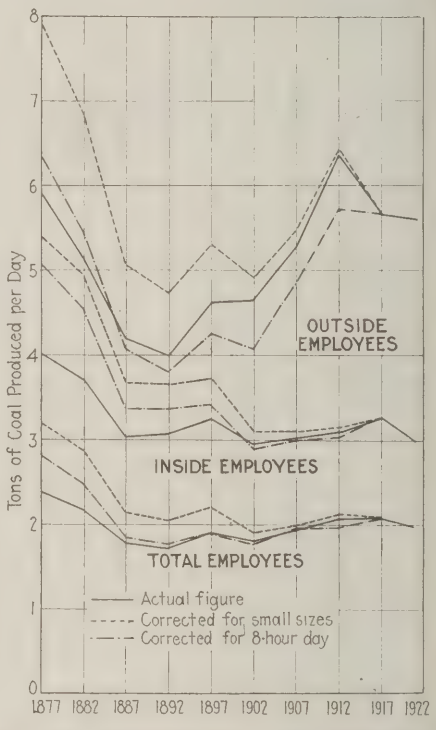

FIG. 47—AVERAGE DAILY PRODUCTION PER EMPLOYEE IN MIDDLE EASTERN FIELD PER INSIDE MAN AND PER OUTSIDE MAN

These curves are corrected for the estimated amount of small-sized coal that went into the culm banks in the earlier years and also for the introduction of the nine- and eight-hour day. These calculations are explained under Fig. 10 in the first article in this series (*Coal Age*, Vol. 23, p. 327). The sizes of coal produced in this region were obtained from very accurate information. These figures were procured in detail for each of the different districts that have been and will be discussed.

In the late seventies mechanical means of cleaning the coal were beginning to be introduced and from 1892 to 1897 the daily production per man employed showed

TABLE XXXVII—AVERAGE DAILY PRODUCTION OF INSIDE MEN IN ASTERN MIDDLE FIELD

	Miners and Miners' Laborers		Inside Company Men		
	Reported	Corrected for Time	Reported	Corrected for Sizes	Corrected for Time
1877	5.23	7.03	16.40	22.1	17.70
1882	5.70	7.57	10.71	14.3	11.40
1887	4.79	5.79	8.32	10.81	8.10
1892	4.65	5.53	8.98	10.69	8.55
1897	5.18	5.96	9.02	10.36	8.57
1902	4.58	4.84	7.96	8.41	7.48
1907	4.67	4.84	8.58	8.86	7.90
1911	4.82	4.91	9.00	9.20	8.16
1913	4.57	4.65	8.94	9.10	8.10
1917	4.88	4.88	9.81	9.19	9.81
1921	4.39	4.39	9.10	8.19	0.10

an upward trend, which continued without interruption until 1912. From this period there has been no increase in the district.

Comparing this production curve with those in the previous articles of this series it is plain that in the Eastern Middle field the output per outside man is about two tons a day less than in either the Lackawanna or the Wilkes-Barre field and approximately three tons less than in the Nanticoke field. There are reasons for this. In pitch mining the rock cannot be separated in the mine because the coal is run out of chutes directly into the mine cars. Therefore this operation has to take place in the breaker and more hand picking is required. Also more men are required for the disposal of the mine rock after it is picked out.

It has been mentioned previously in this discussion that the strippings could not be entirely separated from the underground mining. This further increased the outside forces and therefore reduced the tons of coal produced per outside man.

The true comparison in the districts treated in this series of articles is not between the amount of coal produced per outside man but in the increase in the amount of coal produced. In the Eastern Middle field the production increased from 3.80 tons per man in 1892, the lowest production year, to 5.61 tons in 1921, or an increase of 47.7 per cent. The Lackawanna County district shows a gain of 46.8 per cent; the Wilkes-Barre district, 47.8 per cent, and the Nanticoke district, 75 per cent. This is the highest increase that has so far been brought out, except in the four modern Nanticoke collieries, which showed a gain of 294 per cent. This comparison shows that although the Eastern Middle field increase in production has been good there is still considerable room for improvement, as its increase has been exceeded by almost 50 per cent by the one district in the Northern field wherein conditions are similar—Nanticoke.

The bottom set of curves in Fig. 48 shows the production per day per miner and miner's laborer. Only the final curve corrected for size of coal will be discussed. This is represented by the dot and dash line.

There is a steady downward trend to the year 1902, assuming that data for the year 1897 is in error and the average for 1892 and 1902 is considered instead. From 1902 on, the curve becomes level until 1917. Then there is a considerable drop to 1921.

What sustained the production of the miner and miner's laborer from 1902 to 1917, when in the previous periods there had been a heavy drop? In the discussion of the depth curve in Fig. 42 it was brought out that at about 1902 there was a marked change in the method of mining. The old and wasteful methods were abandoned. Second mining was adopted. Work was more concentrated, thus reducing the length of haul and giving the miner a better turn, therefore increasing his output. The curve also is affected by the inclusion of some stripping coal in the last few years, as has been explained. Comparing this curve with the three previously described districts, it is found that the output per miner and miner's laborer is about one ton more in the Eastern Middle district than in either the Lackawanna or the Wilkes-Barre district but only about half a ton more than in the Nanticoke district, where all the data are influenced largely by the four modern collieries so frequently mentioned. This greater output per miner and miner's laborer is largely due to gravity loading underground. The Lackawanna district shows a decrease of about 43.7 per cent in the output per miner and miner's laborer. The Wilkes-Barre district decrease is 42.9 per cent, and that of the Nanticoke district 54.2 per cent. The Eastern Middle District shows a drop of only 37.9 per cent.

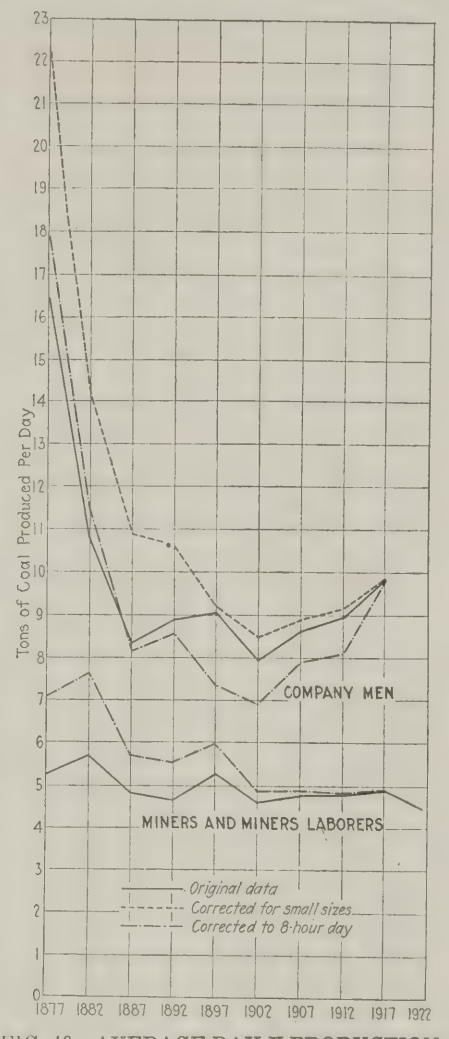

FIG. 48—AVERAGE DAILY PRODUCTION FOR INSIDE EMPLOYEES OF MIDDLE EASTERN FIELD

Corrections are shown for miners and miners' laborers allowing for small sizes not shipped in earlier years and for the introduction of the nine- and eight-hour day in the case of inside company men. In making the calculations it was found that the year 1912 was incorrect, so the points in 1911 and 1913 were calculated and plotted and a line drawn connecting these two points. At the place where this line intersected the vertical division line was considered the correct figure for the year 1912.

The upper set of curves in Fig. 48 gives the average daily output per inside company man. Here there is a tremendous drop, particularly in the earlier years. This output declines to 1887; then it levels off for two periods and takes a final drop in the period ending 1902. From

TABLE XXXVIII—MEN EMPLOYED IN EASTERN MIDDLE FIELD

	Total Employees	Inside Employees	Outside Employees	Miners and Miners' Laborers	Inside Company Men
1877	7,660	4,555	3,105	3,439	1,116
1882	10,268	5,953	4,315	3,886	2,067
1887	11,224	6,500	4,724	4,128	2,372
1892	12,007	6,742	5,166	4,440	2,302
1897	14,044	8,201	5,843	5,211	2,990
1902	12,760	7,817	4,943	4,925	2,892
1907	14,309	9,121	5,178	5,909	3,212
1912	13,688	9,389	4,299	5,945	3,444
1917	10,517	6,681	3,836	4,462	1,219
1921	11,399	7,449	3,930	5,024	2,424

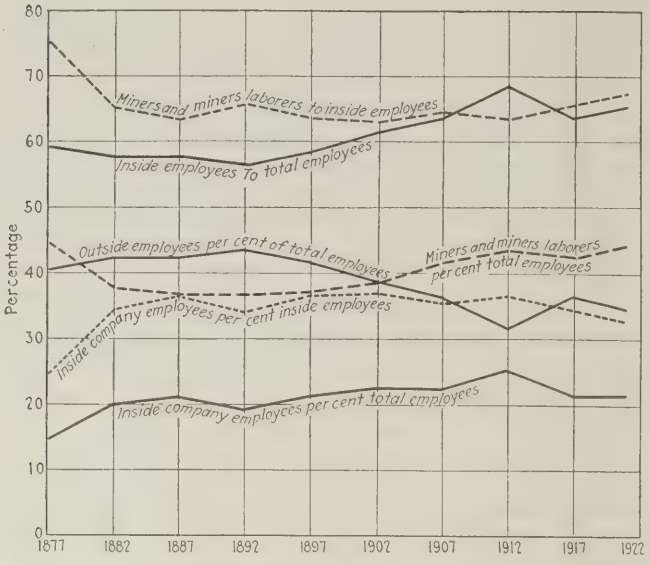

FIG. 49—PERCENTAGE OF EMPLOYEES BY CLASSES IN EASTERN MIDDLE COAL FIELD

Refer to Fig. 12 in the first article in this series (*Coal Age*, vol. 23 p. 329) for a description of the methods used in calculating these curves. The actual number of the men employed is shown in Table XXXVIII and the percentages in Table XXXIX.

this point the curve shows an increased output per man and reaches its highest point in 1917. Then there is a slight falling off.

The output in this district in the earlier years probably is 60 per cent higher than in any of the previously described districts, and even in 1921 it is about 30 per cent higher. Why should this condition obtain? The cause of the difference can be attributed mainly to the method of mining. In the earlier period the work was all done in the steep pitching beds. Here it was unnecessary for the driver to enter the rooms to get the mine cars. The coal was loaded into the trips on the gangways from chutes from the breasts. This reduced the number of mules and drivers. Some hint of this is given in the curves showing the tons of coal hauled per mule per day. By comparing the different curves it will be found that the amount of coal hauled per mule in the earliest periods is higher in this district than in any of the others. But this does not tell the whole tale. In this district the haulage was gangway haulage and therefore more mules were used per team than in the other districts. Therefore fewer drivers were needed and naturally the output per man was higher.

Heavy Pitches, an Advantage in Operation

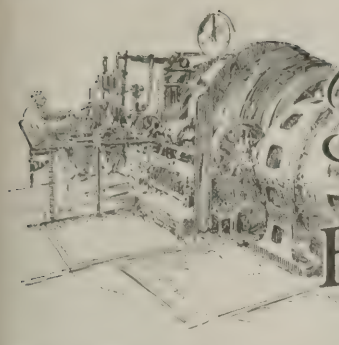
As the change in mining methods came the flatter beds were developed and the average size of the teams decreased. Therefore the number of drivers increased. This, therefore, decreased the amount of coal produced per man. Even now a considerable part of the coal hauled is loaded from chutes and the number of haulage men is less in this field than in the fields where the beds are flatter. The drop in output per inside man has been 48.6 per cent, which is greater than in the Lackawanna County district, where the decrease was 40.2 per cent; the Wilkes-barre district, 40.5 per cent, or the Nanticoke district, 8.4 per cent. A greater decrease in this district is to be expected; as mining conditions have changed considerably, while in the other districts they have remained more nearly the same. Reduction in the Nanticoke district has been retarded by the opening of new mines.

TABLE XXXIX—PERCENTAGE OF VARIOUS CLASSES OF EMPLOYEES TO TOTAL EMPLOYED

	Inside Men	Outside Men	Miners and Miners' Laborers	Inside Company Men	Miners and Miners' Laborers (a)	Inside Company Men (a)
1877	59.5	40.5	44.9	14.6	75.4	24.6
1882	57.8	42.2	37.8	20.0	65.5	34.5
1887	57.9	42.1	36.8	21.1	63.5	46.5
1892	56.2	43.8	37.0	19.2	65.9	34.1
1897	58.4	41.6	37.1	21.3	63.6	36.4
1902	61.2	38.8	38.6	22.6	63.0	37.0
1907	63.7	36.3	41.3	22.4	64.8	35.2
1912	68.6	31.4	43.4	25.2	63.5	36.5
1917	63.5	36.5	42.4	21.1	65.8	34.2
1921	65.5	34.5	44.1	21.4	67.4	32.6

(a) Percentage to total inside employees.

In this district, as in the others, the number of the outside employees has continued to decrease in proportion to the total employed. This is due mainly to the introduction of modern methods of preparing coal. The district has some modern breakers which have considerably reduced the number of preparation employees.



From 1882 to 1902 there was practically no change in the number of miners and miner's laborers but when the character of the mining changed in this period the number increased. This may have been caused entirely by the change in mining methods, or partly by the opening of the thinner beds or by a decrease in the efficiency of the men. Who can fix the proportion of each cause?

Underground Communication by Radio

SEVERAL months ago experiments in underground transmission of the human voice by radio were carried on under the auspices of the U. S. Bureau of Mines, but it was found that natural and artificial interferences—the latter caused by the presence of steel and electrical equipment in the mine—partly frustrated their success. The practicability of underground communication by the wireless telephone had not been indubitably established until recently, when broadcasts from local stations in New York were received aboard a subway train in the East River Tunnel. The success of the experiment is the more remarkable when one considers that much steel is used in subway construction and other disturbances are set up by the inductance from electrical apparatus.

The coal industry is not so much interested in this feat as an accomplishment of science as in the possibility of radio-transmission of the human voice in a mine. Wireless telephony when more perfect probably will remove many objectionable features of our present systems of communication, in which broken circuits caused by roof falls, grounding and leakage through a wet condition about the bare telephone wires make them unreliable. Granting that further refinements in radio will be made we may be optimistic in the belief that some day mine locomotives will be dispatched without wires and the work of mining be otherwise regulated. It is conceivable that the greatest possibilities lie in directing safety and rescue work in mine disasters. Men trapped in remote parts of a mine by explosion or fire could often be saved were it possible to establish communication with the surface as by wireless.

The first step in recognition of the applicability of radio to mining is its adoption for communicating market news and orders from the main offices to isolated mining towns, as is now being done in certain parts of Kentucky.

Practical Pointers for Electrical and Mechanical Men

Starting Synchronous Motors

SYNCHRONOUS motors may be started in any one of several methods. One method usually is selected before the motor is designed and this selection afterward determines the method of starting which is normally used for that particular motor; under certain conditions, however, either one of several methods may be employed.

Most synchronous motors in service around the coal field are used on synchronous motor-generator sets furnishing direct current to the haulage motors, coal-cutting machines, etc. These machines frequently are self-starting, this being possible owing to the fact that it can be very easily accomplished because the synchronous motor is invariably started under no-load.

In the design of the motor an extra winding called a squirrel-cage winding is put on the face of the poles of the rotating field. This winding is used only for starting duty and for this reason it has a relatively low capacity—by this we mean that it can be used only for starting duty and not for carrying any of the direct-current load of the motor-generator set.

In order that the squirrel-cage winding of the synchronous motor shall properly function it is necessary that its resistance be maintained as low as possible, the principle of its operation being exactly the same as that when inserting resistance in the rotor winding of a slip-ring motor to reduce its speed.

An occasional difficulty experienced with this type of synchronous motor is that the starting winding does not bring the motor up to full speed. In this event the trouble usually can be found in the squirrel-cage winding. What has happened is that the resistance of the winding has increased. Fortunately, this condition may be easily remedied by going over the winding and cutting down the resistance of any loose joints. These loose joints often may be located by starting the motor and then shutting it down and feeling the winding for any hot or warm joints.

On account of the large current which would be drawn from the line at the moment of starting if full-line voltage were thrown directly on the motor, a lower voltage is first applied and after the motor has reached full speed full potential is applied. This is accomplished by the use of a compensator, which is essentially an auto-transformer. On low- and moderate-capacity motors the self-contained compensator is used, while for large capacities compensator coils and oil switches are used.

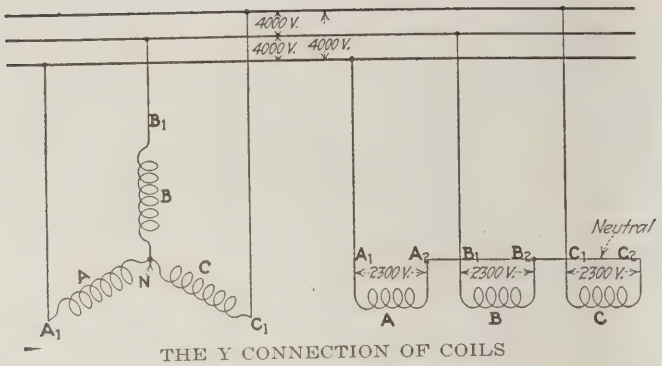
Knotty problems pertaining to equipment and material for special purposes are matters of frequent occurrence with electrical and mechanical men at coal mines. These usually require special handling. Send your experiences and solutions, as well as your questions, to Coal Age. The exchange of such ideas makes the most helpful kind of Practical Pointers.

How to Start Synchronous Motors

The standard method of starting synchronous motors is as follows:

(A) Open the field switch completely if the excitation voltage of the motor is 125. If the excitation voltage is higher than 125 the field switch should not be opened completely but left in the clips connected to a discharge resistance. This prevents any high induced voltage across the collector rings. Exception to the above—if the motor is part of a motor-generator set—the field switch should be left in the clips connected to the discharge resistance irrespective of what the field excitation is.

(B) Throw compensator lever to "start" position.



(C) After the motor has reached constant speed close the field switch; the field rheostat having been previously adjusted to give a field current corresponding approximately to no-load normal voltage, with machine running as a generator. This will cause the rotating field to step in and lock with the stator field poles either quietly or noisily, depending upon whether the squirrel-cage winding has brought the rotating field up to proper speed and the relative position of the stator and field poles at the time the field switch is closed, thus changing the motor from an induction motor to a synchronous motor.

(D) Throw the compensator lever quickly to the "run" position.

The Y Connection Made Clear

A VERY common connection used on alternating current three-phase lines is the Y—sometimes called star—connection. As its name suggests, it is in the form of a Y. This, like the delta connection, may be used in connecting three similar coils to a three-phase alternating-current system. It is used for transformers, motor windings, relay connections, etc.

The important point about the Y connection is that the coils to be connected do not have the same voltage rating as the line wires to which they are to be connected, yet the voltage rating of these coils must bear a certain quite definite ratio to that of the line voltage. This value is equal to the line voltage divided by 1.73;

THE Y CONNECTION OF COILS

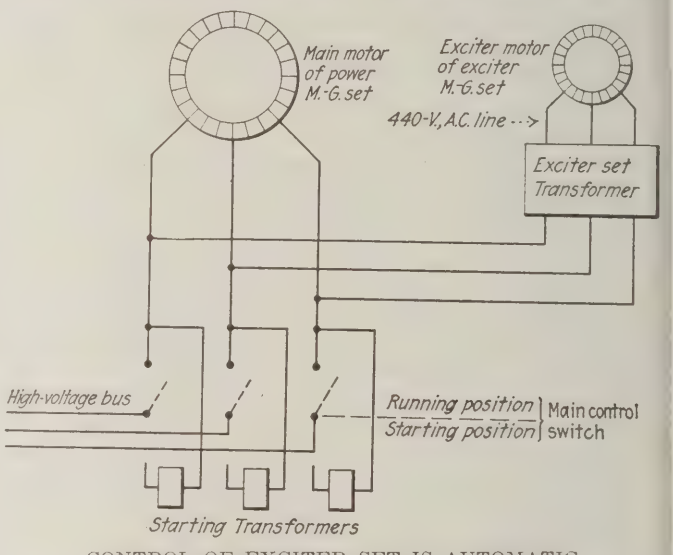
In this connection one end of each coil is connected to a line wire while the other ends are joined to a common point called the neutral. This neutral point may or may not be grounded, depending on the plan adopted for the system.

for example, transformers or coils to be connected in Y to a three-phase alternating-current system of 4000 volts must have a voltage rating for themselves of $4000 \div 1.73 = 2300$ volts. Therefore, we see that 2300-volt coils may be connected to 4000-volt lines if they are first properly connected in Y.

The drawing shows both a schematic and the usual arrangement of the Y connection. Note that the voltage of the coils is 2300 and the voltage of the lines is 4000.

It is important also to note that the same respective ends of the windings are connected to the neutral wire, while the other end is connected to one of the phase wires. Note also that both ends of no coil are directly connected to the line wires as in the delta connection.

To increase the amount of power which can be transmitted over a given line, without changing the size wire, the voltage frequently is raised. If the equipment connected to the original voltage were all delta connected the line voltage could be increased 1.73 times the original and the delta-connected equipment could be connected in Y. This would allow the use of the same equipment and eliminate the necessity of buying complete new equipment for use on the higher voltage. It is therefore obvious that where a line was originally 2300 volts and all the equipment was delta connected the line voltage could be raised to 4000 and the original delta-connected equipment could be still used if connected in Y. Of course the line insulation and equipment insulation would have to withstand the higher value of test voltage.



How to Simplify the Control of Exciter Units for Synchronous Motors

OCCASIONALLY a circumstance arises where a synchronous motor-generator set is installed where the generator voltage of the direct-current generator is not suitable for exciting the synchronous field of the motor. This may occur where the mines are quite extensive and the haulages long, thus requiring 500 volts for the trolley system. In this case it is necessary to obtain suitable voltage to excite the synchronous field from some other source than the 500-volt generator, as this high voltage is not practical for excitation wherever it can be avoided.

The motor voltage under these conditions probably would be 2,300, 4,000 or 4,600. Under these conditions it usually is necessary to install a separate motor-generator set to obtain suitable direct-current voltage to excite the synchronous field. Owing to the small capacity of this exciter motor-generator set the alternating-current motor must be operated on 440 volts alternating current or less. This therefore requires a transformer for stepping the main alternating-current voltage down to that required for the exciter motor and also some form of starting and controlling equipment for the exciter motor-generator set.

To eliminate the added expense of starting and control equipment for the exciter set a scheme of connections was developed by a certain large coal company whereby the motor of the exciter set was always directly connected straight through to the secondary of its supply transformer and the primary of the transformer was connected permanently to the motor leads of the motor of the large motor generator set which supplied the haulage system.

The result of this method of connection was that when the starting voltage was applied to the motor of the large motor-generator set the primary of the exciter set transformer received this same starting voltage, which in turn applied a low starting voltage to the exciter-set motor. Later when the large motor-generator set was up to speed and the full line voltage applied to the large motor the exciter transformer also received full line voltage on its primary and thus gave full normal secondary voltage to the exciter motor.

CONTROL OF EXCITER SET IS AUTOMATIC

The starting of the large motor-generator set will also bring the exciter motor generator up to speed without any additional operations of the attendant. When the large machine is across the full line voltage the little machine gets full normal voltage.

The application of the exciter voltage to the synchronous motor obviously was not affected in any way by this scheme and the operation of the complete equipment was made both cheap and simple; in fact, the scheme greatly reduces the equipment to be maintained and also makes the starting and stopping more nearly automatic.

PERMISSIBLE STORAGE BATTERY LOCOMOTIVE.—The design, construction, inspection and test for permissibility of a storage-battery locomotive outfit intended for use in gaseous mines represents a large amount of work, first on the part of the locomotive manufacturer and secondly on the part of the Interior Department. Detailed information of the first investigation of this nature is presented in Serial 2,449, by L. C. Ilsley, electrical engineer, and H. B. Brunot, junior electrical engineer, which may be obtained from the Department of the Interior, Bureau of Mines, Washington, D. C.

Insulation Resistance Can Be Measured by Use Of Ordinary Direct-Current Voltmeter

Electrical Equipment in Coal Mines Must Withstand Adverse Conditions—Numerous Factors Affect Insulation of Equipment—Insulation Resistance Can Be Measured Without Use of a Megger—Suggestions for Maintaining Insulation Resistance

By E. J. Gealy
Associate Editor, *Coal Age*

THE unfavorable conditions under which electrical equipment about the coal mines is called upon to operate are not always seriously considered and fully appreciated. In places the dust may collect on a motor and clog the air passages and vents, may fall upon oil switches and form a heavy carbon conducting surface for current leaks, may enter the transformer case and cut down the insulating quality of the oil. The moisture in mines, having a relatively high humidity, may keep the electrical equipment continually damp, causing parts to rust and insulating material to swell. Even in places where the moisture content of the mine air is not very high considerable moisture may be splashed on the electric equipment by being brought into the mines on a rainy or snowy day. Especially is this true where a hoisting cable is run over the outside surface or where water may leak from pumps or water lines. In some mines the track is continually in a condition comparable only to that prevailing on roads during rainy weather in a muddy country district. Then again sand used on the rails may easily be picked up, due to the low clearances under haulage motors, and may be carried into the bearings of the equipment. Also the mechanical equipment driven by electric motors frequently, of necessity, is of a type that produces considerable vibration.

Electric Equipment Requires Close Inspection

All these conditions make it imperative that electric equipment be given close inspection and supervision in order to avoid breakdowns and detect possibilities of failures that might result in costly delays.

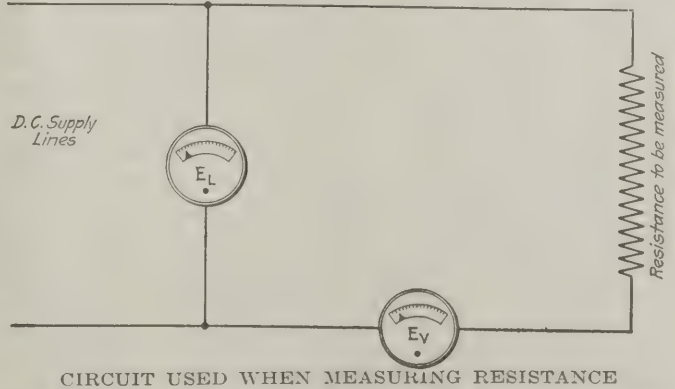
One of the most important things about any piece of electrical equipment is the insulation. Electrical insulation must resist heat, moisture absorption and mechanical breakage. Likewise it must be durable and have a high dielectric strength, or, in other words, a high resistance.

It is therefore necessary to maintain the resistance quality of all insulating material as high as possible in order to prevent breakdowns. It is not only necessary for an electrician or electrical engineer to be able to repair a breakdown to his electrical equipment when it occurs but his most productive efforts are those which result in detecting and avoiding mechanical or electrical breakdowns and thus reducing the expensive consequences which usually follow such breakdowns.

The insulation resistance of electric equipment such as cables, conductors, electric machines and transformers, is sometimes measured and used as a rough indication of the condition of the insulation. It is that resistance measured between the current-carrying parts and the frame of the machine or exterior surface of the conductor. Since large machines or cables have much greater areas of insulation, their insulation resistance will be proportionately lower than for small machines or pieces of cable, yet the insulating material may be in exactly the same condition.

The insulation resistance of any machine will be much lower when hot than when cool, especially when the machine is rapidly heated. A moderate size of low-voltage motor, as usually insulated, when warm from carrying full load, should show an insulation resistance of about 1,000,000 ohms, or, in other words, about one megohm. When cold, the insulation resistance should be many times this amount.

To measure such high values of resistance an electrical instrument called a "megger" is frequently used; it is possible, however, to measure insulation resistance by the use of a supply of direct current from 100 volts or higher and a voltmeter with a reasonably high internal resistance.



The method of measurement is first to read the voltage of the line, then to connect the resistance to be measured in series with the voltmeter and take a second reading. For measuring the insulation resistance of an armature the positive line would be connected to the voltmeter and then to the winding, while the negative line would be connected to the armature shaft or laminations.

The measured resistance is then calculated by using the following formula:

$$R = \left(\frac{E_L}{E_V} - 1 \right) N.$$

R = resistance in ohms;
E_L = line voltage;
E_V = voltage recorded on voltmeter when in series with the resistance to be measured;
N = resistance of the voltmeter in ohms (this value can usually be found on the cover of the voltmeter box).

The method of connecting the equipment is as shown

CIRCUIT USED WHEN MEASURING RESISTANCE

Voltmeter E_L measures the line voltage. E_V actually measures the small current leakage through the resistance. E_L and V may be the same meter used in the two positions shown by first taking reading E_l, then E_V, being careful to keep voltage E_L constant throughout the test.

in the accompanying figure. An example of making such a test would be to have a 110-volt direct-current supply and an internal resistance of 11,000 ohms in the voltmeter used. The voltmeter reads 110 volts in the first position and 5 volts in the second position.

$$E_L = 110, \qquad E_V = 5, \qquad N = 11{,}000$$

$$R = \left(\frac{110}{5} - 1 \right) 11{,}000 = 242{,}000 \text{ ohms}$$

or approximately ¼ megohm, which is very low.

It is obvious that when making this test with a direct-current supply which operates with one line grounded, the grounded line should be connected to the grounded frame or shaft of the equipment to be tested; otherwise, grounding the ungrounded line from the generator would result in a short-circuit.

Pieces of electrical equipment after standing idle for a time absorb moisture; this is especially true during times of suspension. Before placing the equipment into service it is highly desirable to make an insulation-resistance test. If the resistance is low the best thing to do is to heat the insulation slowly to dry it out.

To maintain the insulation resistance of important pieces of electrical equipment forced to be idle or lay as spares it is advisable to keep the insulation warm and dry by connecting it to a circuit of reasonably low voltage and allow a small amount of current to pass through the windings.

Book Reviews

British Coal Mining Industry in the War

MUCH interest has been evinced in America in the methods adopted by the Government of Great Britain and Ireland for the regulation of the coal industry during the war. The measures of socialism then put in operation formed the basis for much of the legislation enacted here when we also aligned ourselves with the Allies in the conduct of the struggle.

In every man can be found in greater or less degree that sense of social obligation on which the British Government so freely relied. It forms, in fact, the gold in the natures of all of us, but it is so heavily alloyed with individualism that as a rule it can form only a spurious currency on which to conduct business. During the war the percentage of social obligation reached such a high figure that it was almost possible to coin it into a basis for social conduct, yet some, like Whitley, were venturesome enough to believe it might be found, not only during the war but afterward, an acceptable substitute for that individual initiative and personal advantage on which, strange to say, the welfare of mankind has been advanced. Observation during the war and afterward showed how grievous was the mistake of these enthusiasts.

Till Sir R. A. Redmayne published his book on "The British Coal-Mining Industry During the War" no one volume contained a complete review of that subject. Redmayne, as former Chief Inspector of Mines and Technical Adviser to the Controller of Coal Mines, Head of the Production Branch, Chairman of the Coal-Mining Organization Committee, Vice-Chairman of the Central Coal and Coke Supplies Committee and Member of the Coal Export Committee, of the Coal Conservation Committee and of the Fuel Research Board, is well able to give a comprehensive and non-partisan *résumé* of the coal industry of Great Britain both during the war and during the period of control that followed. This he has done on behalf of the Carnegie Endowment for International Peace, in a volume published by the Oxford University Press, of which the local address is 35 West 32nd St., New York City.

In an introductory chapter Sir Richard says that in the United Kingdom at the beginning of the war were about 3,000 mines employing in aggregate 1,110,884 persons, the mines being worked by about 1,500 companies, the royalties being vested in some 4,000 persons. In Great Britain as in America it has been too often the custom for politicians, publicists and the public to ignore the fact that the difference between the cost per ton and the selling price was not the same as profit. Sir Josiah Stamp stated before the Royal Commission on the Coal Mining Industry that the profit in the five years before the war was 59c. on coal costing $1.88—surely a satisfactory return, but unfortunately this made no allowance for depreciation, interest and probably obsolescence, which, if deducted, greatly reduce these profits.

Another interesting table contained in this volume shows the home consumption of coal, and we venture to put alongside it the percentages calculated therefrom, and in the table following a calculation of the percentages of American home consumption.

The war produced at first a stagnation in business and the recruiting of miners was not in any way restricted in 1914. "From no class of the community," says Sir Richard, "did the call of patriotism meet a more spontaneous and conspicuous answer than from coal miners. No less than 191,170 men, or nearly 19 per cent of the total personnel—men, boys and women—employed at the collieries of the United Kingdom, joined the colors during the first seven months of the war. . . . The result is still more eloquent of the patriotism of the miners when it is reflected that these men were drawn only from those of military age—that is, between the ages of 19 and 38. It is estimated that 40 per cent of the miners of military age were absorbed into military service, and by far the greater number of these left the mines in the early weeks of the war—that is, in the autumn of 1914." Their places were partly filled by "50,473 persons from other employments, or approximately 5 per cent of the normal personnel of the coal mines," the output declining 13½ per cent.

It is interesting to note that miners in Great Britain are about as irregular in their working habits as ours. From August to February in 1913, before the war, the absenteeism was 10.3 per cent. After the war commenced, from August to February, 1914, probably owing, we may add, to the fact that coal was not greatly needed for some months, the absenteeism was decreased only to 9.8 per cent. Perhaps 5 per cent of this represented sickness either of the individual or in the home.

The early proposals for the reform of the coal industry were not drastic. The Coal-Mining Organization Committee desired to reduce irregularity of work, to utilize holidays for the production of coal, to suspend the "Eight Hours Act of 1908," under which the men worked barely seven hours; to employ more women, to

TABLE I—BRITISH DOMESTIC CONSUMPTION OF COAL 1913 (CALCULATED)

	Industrial Uses	Short Tons	Percentages
(1)	Railroads	16,800,000	8.00
(2)	Coasting Steamers (bunkers)	2,800,000	1.33
(3)	Factories	67,200,000	32.00
(4)	Mines	21,280,000	10.13
(5)	Iron and Steel Industries	34,720,000	16.53
(6)	Other Metals and Minerals	1,400,000	0.67
(7)	Brickworks, Potteries, Glass Works and Chemical Works	6,440,000	3.07
(8)	Gas Works	20,160,000	9.60
(9)	Domestic	39,200,000	18.67
		210,000,000	100.00

These figures are based on estimates from the Coal Commission's report of 1903 with a *pro rata* increase, except where more definite figures are available. The actual total was 211,783,453 tons.

TABLE II—AMERICAN DOMESTIC CONSUMPTION OF ANTHRACITE AND BITUMINOUS COAL

(Based on F. G. Tryon's table for soft coal consumed in a year of active business, *Coal Age*, Jan. 19, 1922).

Industrial Uses	Short Tons	Percentage
Railroads	153,700,000	24.7
Coasting and Lake Trade Bunkering	3,600,000	0.6
Factories*	206,000,000	33.1
Mines (coal only)	22,360,000	3.6
Iron and Steel Industries†	112,780,000	18.1
Gas Works‡	12,220,000	2.0
Domestic	111,100,000	17.9
	621,760,000	100.0

* Includes categories 3, 6 and 7 in Table I and also public utilities (electric).
† Includes coal for byproduct coke.
‡ Assumes that all the coal made into domestic coke is used at coal-gas plants. Does not include on the other hand any of the anthracite used at gas works.

reduce deadwork and to economize in the use of coal. Holidays were reduced by local agreement, and the eight-hour question, as also that of the employment of women, was solved by local understandings. Only in Lancashire and in Scotland had women been employed. In the other districts women but rarely engaged in mine work. No attempt was made to increase the number for fear of creating trouble with the union.

In the years 1915 and 1916 the government tried to speed up coke production, mainly for the TNT obtainable. "It is on record," says Sir Richard, speaking about conditions prior to the war, "that Germany even occasionally imported coal of high coking quality from Great Britain, extracted the byproducts and exported the coke to England." Soon Great Britain was producing so much coke that she was unable to find uses for it. Byproduct coke could not be burned in open grates or for the raising of steam except under forced draft. Consequently in making arrangements to exchange coal for the materials needed from foreign neutral countries, Great Britain had to stipulate that they take a proportion of coke. This speedily reduced the surplus. Germany also found herself overstocked with the same commodity.

As the war progressed the French began to be short of miners and proposed to the British Government that it send men to operate French mines. But ultimately French miners were brought back from the front. However, the author of the volume reviewed visited France to facilitate the transfer of men and found that many of the mines could be worked only at night as they were being shelled by day and some of the coke workers had to hide in dugouts while their ovens were being bombarded.

Among other extraordinary measures—to us, at least, they seem unusual—was to endeavor to induce the people to use anthracite for domestic heating and cooking. The people believed it could be burned only in a closed stove and took most unfavorably to its use. It had to be started with bituminous coal and when burning should not be poked. Now, an Englishman is never so happy as when he has a poker in hand and is turning over the coals in the grate.

Under the anathematized Dora (Defense of the Realm Act) the Controller of Mines issued an order on March 16, 1918, ordering that no owner of coal mines shall without previous written notice to the Controller incur any expenditure on the following objects: (1) the sinking, widening or deepening of shafts (including shafts that do not come to the surface) or the continuance thereof; (2) the driving of slants or adits for the purpose of hauling coal or the making of cross-measure or rock headings; (3) the opening or reopening of seams; (4) the erection or acquisition of any additional buildings, plant or machinery not strictly required for purposes of repairs or maintenance; (5) the selling or other transferring of the ownership in any mine or part of a mine. This first restriction was seriously considered in the United States and during the war might have been enforced with advantage. It was actually put in effect in Great Britain, and the lack of development considerably hampered production after the war, for England has not for many years had more mines than it needs.

In this review a few of the high lights have been chosen from its 358 pages measuring 5¼ x 9⅝ in. It is an orderly presentation of the events in the coal industry from the somber First of August, 1914, to the glorious Fourth of July, 1921, when the men went back to work after a long and bitter strike.

U. S. Bureau of Mines, Its Legal Status, History, Purpose and Functions

PURSUING its intention of preparing a series of monographs on the various service organizations of the United States Government, the Institute of Government Research has published its third treatise, covering the history, activities and organization of the U. S. Bureau of Mines, beginning with the organization of the Technological Branch of the U. S. Geological Survey, which had its origin in the order of April 2, 1907, of the Secretary of the Interior.

At an even earlier period the U. S. Geological Survey, in accordance with the Act of Feb. 18, 1904, had begun the work of fuel testing, establishing a station at the Louisiana Purchase Exposition in St. Louis and removing later in 1907 to the Jamestown Exposition, at Norfolk, and to Denver, and opening fuel-testing laboratories at Columbus, Pittsburgh and Washington. An immediate cause of the extension of the Technological Branch was found in the terrible coal-mine explosions in December, 1907. Stations for mine-rescue apparatus were established at Pittsburgh, Pa., and Urbana, Ill., in 1908, followed by one at Knoxville, Tenn., and Seattle, Wash. The Bureau of Mines was created by the Act of May 5, 1910.

The U. S. Bureau of Mines has since made co-operative agreements, and in 1920 had thirteen of these contracts with as many public bodies and had greatly extended its activities. These the book undertakes to summarize in detail, giving the laws under which the Bureau operates and a bibliography of the publications dealing with its activities The book contains 162 pages measuring 5¾ x 8⅝ in. The publisher is the Johns Hopkins Press, Baltimore, Md.

THE FRENCH ARMY seems to be something in the nature of a Fact-Finding Commission.—*Philadelphia Inquirer.*

Problems of Operating Men

Edited by James T. Beard

Timbering High Falls on Entries

Old Entries Often Develop High Roof Falls—Timbers Supported on Collar Beams Set in Hitches Cut in Solid Formation Above Coal

IT HAS been with much pleasure that I have read the several letters of contributors to *Coal Age*, written in response to my inquiry, which appeared in the issue March 1, p. 380. We were then retimbering an old slope that had fallen to a great height in many places. I stated at that time that we made a mistake in the start of the work, by attempting to use double timbering, supporting the collar beams on legs set in the entry.

The sequel has proved that I was right in contending that we had made a bad start. Instead of using the legs to support the collar beams, these should have been set in hitches cut in the rib. At that time, I do not seem to have made myself clear in the matter that these hitches should be cut in the solid formation, say 3 ft. above the coal, instead of in the coal, as shown in my previous sketch.

In order to make the situation clear, I am now sending a few sketches that will serve as a little history of

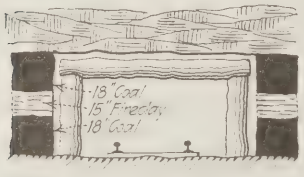


Fig. 1 Slope as first Timbered

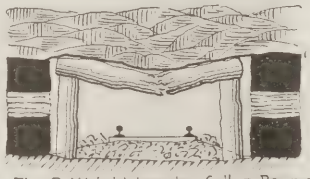

Fig. 2 Weight breaks Collar Beams

Fig. 3 First Form of Timbering High Roof falls

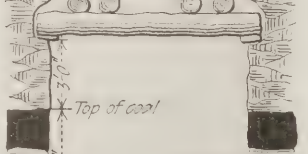

Fig. 4 Final Method that saved Timber and was successful

HEAVY SQUEEZE CAUSES HIGH ROOF FALLS

the work. In my previous letter, I also failed to show that the coal lies in two benches separated by a 15-in. fireclay parting, as indicated in the present sketches.

In Fig. 1 is shown the original slope where the roof supported in the usual manner known as "double timbering." In Fig. 2, is shown what took place some time later and represents the condition of affairs when we started to retimber this old slope.

In Fig. 3, is shown the method we tried first, using double timber with long legs set on the bottom. This was fully explained in my previous letter. Finally, Fig. 4 illustrates what I intended to explain before. Here, the collar beams are shown as supported in hitches cut, in the solid formation, about 3 ft. above the coal. This method has the advantage of doing away with the legs supporting the collar beams in the first plan and avoiding the danger of these legs being knocked out by a derailed car.

In closing, I may add that in places where the coal had been taken out, solid cribs were built on each side of the road and short legs used to support the collar beam in each timber set. These short legs were set on good solid timbers forming the cribs. MAC.

River Herbert West, N. S.

Mine Doors and Safety

Cause of many accidents—Recommendations by the Safety Committee—Standard form of door adopted proves satisfactory—Advantage gained in its use.

SPEAKING of mine accidents to which so many writers have referred in recent letters in *Coal Age*, I am reminded of the action taken by the Safety Committee in one of our mines where a water bailer was killed a short time ago by coming in contact with the top of a door frame. His head was caught between the frame and the top of the car. Previously, in the same mine, a brakeman had been seriously hurt when squeezed between a car and the side of a door frame.

As the result of these two accidents, the Safety Committee took it upon themselves to look carefully into the matter of mine doors, with a view to recommending the adoption of some type of door that would insure greater safety to drivers and to men walking the road when going to and from their work. It was agreed that the usual form of mine door was a source of many accidents that a little study of the situation might avoid.

NEW TYPE OF MINE DOOR INSTALLED

Later, on the recommendation of the committee, we have installed, in our advance work, three doors composed of wood and galvanized tin. By this form of construction, the door is made very light as compared with the common type of door built only of wood. For that reason, the door can be made wider as its weight does not pull the frame out of alignment.

There are two features regarding the form of door adopted that are worthy of mention. First, the width of the door opening is made sufficient to give a good safe clearance between the side of the car and the door frame. Second, the usual 6 x 6-in. lentil of the door frame is replaced by a 2 x 6-in. plank, laid flatways, which gives 4 in. more headroom than before.

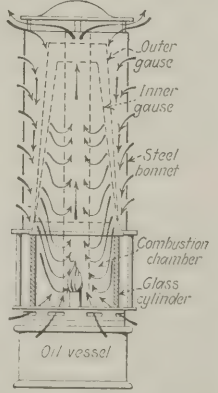
In addition to this type of door, the Safety Committee recommended the installation of automatic doors throughout the mine and the replacing of all main doors by overcasts. The latter had already been done in all of our larger mines and the same practice will eventually be followed in this mine.

While the adoption of the new type of door was undertaken as an experiment, the result has proved so satisfactory that it has since been decided to standardize this form of mine door, which will be erected henceforth in all advance work. Everything considered, it has been generally agreed that the new type of door insures greater safety in the operation of the mine.

The advantages gained by the adoption of this door as a standard are briefly the following: No matched or grooved lumber is needed in the construction, and the galvanized "Armco" tin does not rust. There is required a much lighter frame, which permits increased clearance each side of the track and more headroom.

Pikeville, Ky. GEORGE EDWARDS.

Circulation in Safety Lamps



Eloin principle exaggerated—Relates to main air supply entering lamp below flame—Experiments prove that some air enters lamp through gauze chimney.

THE inquiry of Francis Devlin, *Coal Age*, Feb. 8, p. 260, regarding the question of the entry of gas-charged air at the top of the chimney of a safety lamp and descending to the flame, has a direct bearing on the explanation I made, a short time ago, of the cause for the elongation of the flame of a safety lamp in a firedamp mixture.

Some writers have since taken exception to my ideas as then set forth. However, I believe it is wrong to understand that the meaning of the Eloin principle of ascensional circulation within a safety lamp is that no air enters the lamp, except what is admitted through the ports of entry below the flame. My understanding is that the principle of ascensional circulation applies only to the main air supply.

WHAT THE ELOIN PRINCIPLE ACCOMPLISHES

It seems to me that the Eloin principle is much exaggerated. For example, if the lower ports of entry, in the Wolf, the Koehler or other similar lamp, are sealed the lamp becomes at once one of the Clanny type, the air entering the lamp above the glass and descending to the flame.

CIRCULATION IN SAFETY LAMP

The only purpose of providing for the entrance of air at points below the flame is that, by so doing, there is less conflict of the ascending and descending currents, which lessens the tendency of the lamp to smoke and improves the illumination. My belief is that, in every lamp of this type, there is a primary ascending and a secondary descending circulation that partakes, more or less, of the character I have attempted to illustrate in the accompanying figure.

Let me urge any one who may be skeptical of this condition to place a Wolf or Koehler lamp where its chimney will be surrounded by an atmosphere of smoke, while fresh air is permitted to enter the ports of entry below the flame. Removing the bonnet from the lamp will give a better opportunity to observe the result, which will be found quite similar to what I have shown in the figure.

The smoke will enter through the gauze chimney of the lamp and be observed to descend to the flame in the combustion chamber, the current descending in close contact with the cooler surface of the glass, while the ascending current occupies the center of the chimney forming a column above the flame, as indicated by the dotted lines in the figure. It will be observed that this central column has a greater velocity, which is suggestive of a greater degree of heat.

From this center column, extending all the way from the flame to the top of the chimney, the temperature decreases outward toward the wire gauze forming the chimney. This decrease in heat results from radiation and absorption. The annular space between the two gauzes, expanding gradually from the bottom to the top, tends to accentuate the keeping of the gauzes cool. Naturally, the outer gauze is the cooler of the two.

In conformity with the principle of all fluids that movement is always toward a point of lesser pressure, it appears logical to infer that there will be such a movement, however slight, through the cooler part of the chimney to the zone of least resistance surrounding the flame. It is my belief that this movement will be intensified when the lamp flame is lowered to a height suitable for the detection of a flame cap, in testing for gas.

DETECTING THIN LAYER OF GAS AT ROOF

Allow me to suggest that this is the principle involved in the hollow standards of the Ashworth-Hepplewhite-Gray lamp, which is designed to conduct a thin stratum of air, lying at the roof, downward to the flame of the lamp. In my opinion, the annular space between the double gauzes of these lamps serves much the same purpose and provides for the entry of air at or near the top of the lamp.

Undoubtedly, there are conditions under which gas escapes from the roof in such small quantities that its presence cannot be detected by either of the lamps named. However, the fault will generally be found to be owing to the rapid diffusion of the gas, thereby producing too low a percentage of gas to permit of its detection in the lamp.

My conclusion is, therefore, in support of the claim of Mr. Devlin, that under such conditions the gas enters the top of the lamp in sufficient quantities to be detected on the lamp flame, assuming the lamp is constructed on the Eloin principle. I. C. PARFITT.

Washington, D. C.

Foremen, Awake!

Need for special thought in the prevention of accidents in mines—General attitude of foremen toward dangerous practices of miners.

ACCIDENTS occur in so many ways, in the mines, that it requires the giving of special thought and attention to means for their prevention. Observation of conditions, in visiting different mines, leads one to wonder if the general mine foreman is thoroughly awake to his responsibilities, in respect to many dangerous practices that are permitted to go on with little more than a smart reprimand.

The district mine inspector is probably better able to judge fairly, in this respect, because the duties of his office require him to visit a large number of mines, where he is continually afforded opportunities for observing unsafe conditions and practices. Also, as inspector, he must investigate the more serious and fatal injuries of workmen hurt in the mines, and determine

the cause and fix the blame for all accidents occurring in his district.

When an inspector visits a mine, he has no other thought than that of safety in the operations going on about him. His mind is not taken up, or his thought absorbed, in devising means for the more economical extraction of the coal. His whole attention is riveted on the one idea of making the mine safe for work.

It is quite different with the average foreman, who is in charge of the mine and whose thoughts are necessarily divided among the many duties that rest on his shoulders, in reference to maintaining a satisfactory output of coal and keeping down the cost-sheet, which he knows is closely scrutinized by the superintendent and manager. However, the capable foreman can always train himself to meet the responsibilities that rest on him and still have due regard for the practice of safety among his men.

The best proof that the ordinary foreman fully appreciates the true value of safety is shown by his attitude toward workmen who continually follow dangerous practices, day after day. When the attention of the average foreman is called to the matter he justifies himself by saying, "I have told those fellows that they would get theirs one of these days if they didn't change their ways."

It is most remarkable that this type of foreman, however, would not allow a workman to meddle with a machine that he was likely to injure in a way that would cost the company a few hundred dollars or more. At the same time, he will permit a workman to follow a dangerous practice that he knows will, sooner or later, cost the man his life and perhaps obligate the company several thousand dollars in compensation.

Considerations such as these lead me to exclaim, "Wake up, mine foremen!" The wide-awake foreman or assistant foreman will, in the course of a year, find many opportunities to save men from painful injuries or possible death. To do this, however, he must see that every man is following safe practices in performing his work. Only so, can he be a real foreman.

Pikeville, Ky. GEORGE EDWARDS.

Inquiries Of General Interest

Working Coal Seam With Heavy Slate Parting

Lower Bench Worked Out First—Slate Parting Dropped a Short Distance Back From the Face —Upper Coal Taken Out When Retreating

I AM anxious to obtain suggestions as to the cheapest and safest manner to work a double seam of coal, with a view to extracting all of the coal at the least expense for deadwork.

In our mine, the bottom coal has a thickness of 52 in. This is overlaid with 30 in. of slate parting, which we term "middleman." The upper seam overlying the middleman is also 30 in., and is a good quality of coal. Overlying the upper seam is a sandrock, which makes a good strong roof.

While different ways have been proposed for working out these two seams with least expense for handling the refuse, I am confident that we can learn much from the experiences of *Coal Age* and its practical readers. It should be stated that the slate parting is of a nature that it cannot be held up for any length of time.

Staub, Ky. SUPERINTENDENT.

In this case, there is 4 ft. 4 in. of coal in the lower seam and 2 ft. 6 in. in the upper seam, making 6 ft. 10 in. of coal in all. The thirty inches of slate separating these two seams of coal is a large amount of refuse to handle, which makes it important to select some method that will avoid that necessity.

It is stated that this slate cannot be held up for any length of time. Therefore, taking everything into consideration, it would seem that the safest and most economical method of working to adopt would be to take out the lower coal first by driving the entries in that seam in advance of the work above.

As these entries are advanced, the slate must be well posted for a distance of three or four yards back from the face. A little later, these temporary timbers are knocked out and the slate allowed to fall, after which it is gobbed on one side of the road, forming a solid wall on the side opposite to that on which the rooms are turned.

It is assumed that the coal in the upper seam makes a good roof in the extraction of the lower seam or in the first working, both in the entries and the rooms. This 30 in. of coal forming the upper seam is taken out, later, on the retreating plan, or in the second working when drawing back the pillars.

This proposed plan has, of course, only been described in a general way and must be modified to suit conditions in the floor, which have not been stated in the inquiry. Much will depend, also, on the depth of cover and thickness of the sandstone forming the roof in the upper seam. The necessary modifications must be worked out in accordance with these and other data, not given. We hope for many good suggestions from readers.

Juggling Mine Props

KINDLY explain through the columns of *Coal Age*, the meaning of the term "Juggling Props." Has this term any relation or significance in reference to the building of a jugular manway, in a thick anthracite seam where the inclination is steep? As I recall, such a term is used in that instance. M. J. U.

Freeland, Pa.

The expression "Juggling Mine Props" is a new one to us, we never having heard it used in connection with coal mining. The meaning of the word "Juggling" is to resort to an underhanded trick. It is an entirely different word from the word "Jugular," as used in reference to a manway of triangular shape constructed in an anthracite chute, on a steep inclination. A jugular manway is formed by leaning long props against the rib of the chute so as to form a narrow manway by which the miners can enter or leave the chute. The primary meaning of this term has reference to a throat passage, which the jugular manway in a measure represents. The two terms have a very different significance and bear no relation to each other.

Examination Questions Answered

Alabama Foremen's Examination, Birmingham, Jan. 22, 1923

(Selected Second Class Questions)

QUESTION—*What qualifications are necessary to make a successful mine foreman other than those required by the law?*

ANSWER—Besides being of the required age, a citizen of the United States, of moral character, temperate habits and having the necessary experience in mining, the successful foreman must be a good judge of human nature and able to discern the qualities and capabilities of men. In all his dealings he must be just and firm, showing no favoritism, but giving every man a square deal and making no promises that he may not be able to keep. He must be industrious and painstaking in his habits, setting an example for his men to follow and never asking them to do what he is unwilling to do himself.

QUESTION—*(a) What is a water gage and what is it used for? (b) A water gage shows a reading of 3 in.; what is the ventilating pressure per square foot? (c) What is the total ventilating pressure in an airway 8 x 10 ft., in section?*

ANSWER—*(a)* A water gage consists of a bent glass tube having the form of a letter U. The end of one arm of the tube is bent at right angles to permit of its being inserted through a hole in a partition or door separating the intake from the return airway. When thus placed in position on a partition or door between the intake and return airways, in a mine, one arm of the tube is subjected to the greater intake pressure, while the other arm is open to the lesser return pressure. As a result, the water is depressed in the former and rises an equal amount in the latter arm. The difference in water level is a measure of the difference in pressure between the two points, or the pressure required to pass the air from the intake to the return where the measurement is taken.

(b) Each inch of water-gage reading corresponds to a pressure of 5.2 lb. per sq.ft. A 3-in. reading of the gage indicates a pressure of $3 \times 5.2 = 15.6$ lb. per sq.ft.

(c) The sectional area of an 8 x 10 ft. airway is $8 \times 10 = 80$ sq.ft. and a 3-in. water-gage reading for that airway indicates a total ventilating pressure of $80 \times 15.6 = 1{,}248$ lb.

QUESTION—*How can you tell whether or not any obstruction is in an airway or air-course that you have not passed through?*

ANSWER—Any obstruction to the passage of air in an airway will cause a corresponding increase in the pressure or water gage producing the circulation, assuming the ventilating fan is running continuously at a constant speed. Therefore, any observed increase in the reading of the water gage, while the fan is running at its usual speed, would indicate the presence of some obstruction to the passage of air in the airway and the cause should be sought and removed.

QUESTION—*What materials are best for tamping shots and why?*

ANSWER—Clay, sand and dirt taken from the mine roads form the best materials for tamping shots. Such material being incombustible, cannot add to the volume or intensity of the flame produced by the explosion of the charge, and there is less danger of flame being projected from the mouth of the hole when the shot is fired.

QUESTION—*What is the rubbing surface in an airway, 4 ft. high, 9 ft. wide and 1,000 ft. long?*

ANSWER—The perimeter of this airway is $2\ (4 + 9) = 26$ ft. Then, the length of the airway being 1,000 ft., the rubbing surface is $1{,}000 \times 26 = 26{,}000$ sq.ft.

QUESTION—*Under what conditions would you consider the use of mining machines not advisable?*

ANSWER—The use of mining machines is not recommended where the floor of the seam is quite irregular, which may cause an excessive loss of coal in the mining; or when the seam contains boulders or nodules of pyrites that would interfere seriously with the mining of the coal. It may often prove desirable to mine a soft friable coal with picks, rather than to employ machines for that purpose. This can only be determined by experience in the seam in question. Machine mining is not advisable and may be wholly impracticable on certain steep pitches, owing to the difficulty of keeping the machine up to its work.

QUESTION—*What conditions call for the use of puncher machines for mining?*

ANSWER—The use of puncher machines is often found an advantage where boulders or nodules of pyrites abound in the strata where the mining is done. In the use of the puncher, it is possible to direct the fit so as to avoid such obstructions and cut around them so that they can be removed without difficulty. This is not possible in the use of a chain machine.

QUESTION—*What conditions would make the use of chain machines most desirable?*

ANSWER—Chain cutting machines are best adapted to the mining of coal in a generally level seam that is free from boulders and other obstructions that impede the mining.

QUESTION—*Do puncher or chain machines produce the most dust in the mining of coal?*

ANSWER—Puncher machines will produce a larger quantity of cuttings, owing to the greater height of the mining at the face of the coal. On the other hand, the cuttings produced by the puncher are coarse and there is less fine dust than what is produced in the use of chain cutters.

QUESTION—*What dangers arise from blasting coal out of the solid?*

ANSWER—Where solid shooting is practiced, there is a tendency on the part of the miners to employ excessive charges of powder. The charge is often laid too deep with the result that the shot blows its tamping. Solid shooting requires both experience and skill in the placing of shots to avoid danger.

QUESTION—*What dangers arise from lack of judgment in placing shots?*

ANSWER—When the miner lacks judgment and experience he is prone to locate and point his hole in a direction that requires more work than what the charge is capable of doing, and the result is a blownout shot with the production of much heat and flame and a local explosion of dust is very liable to happen, which may or may not be propagated throughout the mines.

Western Kentucky Strike Ends on Owners' Terms; Two-Year Pact Signed

Scale committees of the Operators' Association and District No. 23, United Mine Workers, met May 4 at Madisonville, Ky., and signed a wage contract for a period of two years, the union officials agreeing to accept the operators' contention after an all-day meeting of the district executive board and scale committee of the mine workers. It is understood that the union officials decided to sign a two-year contract provided there was no change in the working conditions.

Five thousand union miners in Christian, Webster and part of Hopkins County, excluding the St. Bernard Mining Co. in the latter county, are involved by the signing of the new wage scale.

The men went on strike March 31. They were ordered out because the union officials favored a one-year contract and the operators stood firm for two years.

Brent Hart, president of the Hart Coal Co., announced that he would not sign the wage agreement unless men he now had in his employ, who had been working since the strike became effective, were taken care of by the miners' union. Mr. Hart is a member of the Operators' Association. Other mines of the Operators' Association are expected to resume work as soon as railroad cars are available.

To Call Governor Small in Herrin Quiz

The Illinois legislative committee which has been investigating the Herrin massacre resumed its sessions in Springfield, Ill., Monday, and if present plans are perfected the committee probably will draft its final report in three weeks. Governor Len Small probably will be summoned to appear before the committee soon and it is probable also that Former Assistant Attorney General Charles W. Middlekauf, who conducted the prosecution of the cases at Marion, also will be called.

When members of the committee returned from a three days' session at Herrin, they expressed the belief that Former Sheriff Thaxton of Williamson County, who was not a willing witness at Herrin, should be brought to Springfield. While it is generally conceded that Thaxton, who is now County Treasurer of Williamson County, will not reveal information to the committee, it is pointed out that if he commits perjury in this county the case could be taken before the grand jury for investigation. If indictments were returned he would be placed on trial in Springfield, not in "bloody" Williamson County.

An effort is being made to locate W. J. Lester, owner of the Williamson County strip mine where the massacre of June occurred. If Lester is located his testimony may be taken at a session of the committee to be held at Chicago.

National Coal Association Intervenes in Petroleum Case Against Mo. Pac.

The National Coal Association has filed a petition with the Interstate Commerce Commission intervening in the case of the Western Petroleum Refiners' Association against the Missouri Pacific R.R. and other carriers. At the same time, the Traffic Bureau of the National Coal Association sent a letter explaining its action and the case to directors, secretaries of local coal associations and members of the Railroad Relations Committee of the national organization. Inclosed was a questionnaire designed to disclose cases in which coal has been displaced by fuel oil.

The complaint of the petroleum association, representing oil producers in the mid-continent field, was filed with the Interstate Commerce Commission more than a year ago. It was amended about four weeks ago.

In the petition complaint is made against alleged discrimination in freight rates against fuel oil and in favor of coal east of the Mississippi River and north of the Ohio. A large number of railroads are named defendants, some of them extending into the South, so that practically the complaint involves all the principal carriers east of the Mississippi. The commission is petitioned either to require a reduction in the oil rates or an increase in coal rates. The general experience has been that in cases where an adjustment in rates has been directed by the Interstate Commerce Commission the railroads, if possible under the order, will make the adjustment by raising the lower rate rather than by lowering the higher one.

The National Coal Association will contend that freight rates on coal are sufficiently high and probably will argue that the competition of the mid-continent oil producers east of the Mississippi is not with coal but with fuel oil from the Eastern seaboard. Facts developed by the questionnaire sent out by the Traffic Bureau as to the extent of displacement of coal by fuel oil are expected to prove valuable to the coal industry in other than this case before the Interstate Commerce Commission.

The increasing use of gasoline is causing an increased volume of the residue, fuel oil, which is seeking a market energetically, it is said.

Union Appeal from McClintic Injunction Heard; Operators Seek Permanent Order

The U. S. Circuit Court of Appeals, sitting at Richmond, during the first week of May heard arguments on the appeal by the United Mine Workers of America from the decision of Judge George W. McClintic, of the U. S. District Court for the Southern District of West Virginia, restraining the collection by the union of money by check-off.

Pending final decision by the Court of Appeals, the decree of the District Court in so far as it affects the collection of the check-off and therefore the agreement between the United Mine Workers and defendant coal companies has been suspended, so that the union is at the present time collecting the check-off money. Following the strike non-union companies obtained the injunction to restrain the companies signatory to a closed-shop agreement with the union from paying over any money collected through the check-off on the ground that the funds so collected would be used to aid in the organization of their mines.

A meeting of about twenty-five operators of the Kanawha field was held last week to consider the steps to be taken in preparing evidence to be submitted to the District Court on May 21 before Judge McClintic. This hearing will cover thirteen restraining orders granted by Judge McClintic during the strike last summer to prevent interference with the operation of non-union mines. The case will consume more than two weeks and will require the testimony of between 200 and 300 witnesses.

The new hearing is on the question of whether the restraining orders shall be made permanent. One injunction will be selected as a test—inasmuch as the various orders are similar in text—and upon the decision will rest the fate of the remaining orders. Companies in the Winding Gulf, New River, Kanawha and Williamson fields are parties to the injunction.

March Tidewater Dumpings Largest of Any Month for a Year

A total of 3,315,000 net tons of soft coal, according to the U. S. Geological Survey, was moved through North Atlantic ports in March, as compared with 2,708,000 tons in February and 3,189,000 tons in January. The aggregate shipments were larger than in any month since March, 1922, when they were greatly stimulated by anticipation of the strike and totaled 3,357,000 tons. The cumulative shipments at the end of the first quarter of 1923 stand at 9,212,000 tons, against 8,307,000 tons in the same period of 1922.

TIDEWATER BITUMINOUS COAL SHIPMENTS FOR MARCH 1923
(In Net Tons)

Destination	New York	Philadelphia	Baltimore	Hampton Roads	Charleston	Total
Coastwise to New England	138,000	48,000	105,000	1,039,000	5,000	1,335,000
Export	.....	29,000	111,000	232,000	12,000	384,000
Bunker	249,000	38,000	28,000	168,000	6,000	489,000
Inside capes	.....	149,000	145,000	71,000	.....	365,000
Other tonnage	537,000	1,000	1,000	203,000	.....	742,000
	924,000	265,000	390,000	1,713,000	23,000	3,315,000

Seek Aid of Chamber of Commerce for Coal Commission; Lay Coal Shortage to Labor and Railroads

At the group luncheon meeting of the Natural Resources Division of the Chamber of Commerce of the United States, which held its eleventh annual meeting in New York City this week, two resolutions were submitted, one by the National Coal Association calling upon the officers and directors of the chamber and its affiliated bodies to assist the U. S. Coal Commission in its work, and the other offered by the Charleston Chamber of Commerce placing the blame for coal shortage on labor, followed by the failure of transportation lines when work was resumed at the mines.

The convention continued its sessions from May 8 to 11, the meetings being held in various places and addresses being made by many noted speakers, including Herbert Hoover, Secretary of Commerce.

Those who spoke at the session of the Natural Resources Division, held on May 9, and their subjects were: "Some Problems of Coal Distribution," J. D. A. Morrow, president, Morrow Callahan Coal Co., Pittsburgh, Pa.; "Labor and Its Effect on the Cost of Industrial Coal," J. G. Bradley, president, Elk River Coal & Lumber Co., Dundon, W. Va.; "Economic vs. Legislative Solution of the Coal Problem," George H. Cushing, Cushing's Survey and Service, Washington, D. C.

National Coal Association Presents Resolution

The resolution offered by the National Coal Association was as follows:

"Whereas since the beginning of the World War the production and the transportation of coal have stood out among the country's foremost industrial problems; and

"Whereas coal is the most essential factor in the production, manufacture and transportation of all commodities and constitutes the indispensable material basis of modern industrial and economic life; and

"Whereas the problems encountered in the coal industry are not peculiar to it alone but are found to a greater or less extent in all industries throughout the country: Now, therefore be it

"Resolved, That this body here assembled, representative of all the business and industrial life of the nation, authorizes and instructs its officers and directors to assist in every possible way the work of the U. S. Coal Commission in its investigation of the coal industry; and be it further

"Resolved, That all local and national associations and organizations affiliated with this body be urged to assist its officers and the U. S. Coal Commission in its work and to aid in obtaining the widest publicity as to the facts developed by the commission."

Stripped of its preamble the resolution of the Charleston Chamber of Commerce, read:

"Resolved, That, first, the continued operation of the non-union fields should be encouraged, and that their field of operation should be increased to the end that they could save the nation from disasters in the future which have threatened in the past.

"Second, that both the coal shortage and high prices from which the public suffered is a result not of the faults peculiar to the coal business but (a) from the periodic stoppage of production by the power of a labor monopoly; and (b) the inability of the transportation system of the country to respond to the extraordinary demands made upon it as a result of the shortage created by the strikes."

Mr. Cushing said that to remove the causes of popular complaint against the coal industry—intermittency of coal supply and the fluctuation of prices—it is proposed to put coal under federal regulation and that raises the question whether popular safety is most assured under private business or under state domination.

The statement that anthracite prices have alone involved the whole coal industry in danger of federal regulation is erroneous, he said. Anthracite prices are only one of the causes. Public utilities and railways, which have the selling price of their services and the maximum earning capacity of their capital fixed by law, cannot pay competitive prices for coal and remain solvent. The alternatives are to release the householders, public utilities and railways from regulation so that they can protect themselves in the open market for coal or to put coal under regulation on the theory that a producer must be equally bound with his customers. If the latter is done then the business of other people who sell other things to these controlled groups also will have to be regulated in time.

Responsibility attaches only to ownership. The operator owns the mines and is responsible for production. He has been able and eager to produce at least 20 per cent more than is needed. He has discharged his obligation. The merchant owns the facilities for distribution. He has 50 per cent more facilities than are required. He is eager to use them. The merchant has therefore discharged his obligation to society.

The miners control the energy and the skill for the production of coal. They have shirked; they have declared local strikes; and twice they have declared nationwide strikes.

The carriers own the facilities for transportating the coal. They have less facilities than are needed. The carriers, however, are literally operated by the state. For the failure of the carriers, the state is responsible. The state alone is responsible for policing the country. It has failed to prevent the miners from conspiring to limit coal production. The two causes of the coal distress are the failure of the railroads to deliver and of the miners to mine the coal. For both of these the state must accept responsibility.

Reforms Proposed for Coal Industry

Mr. Cushing said it is proposed to reform the coal industry by stabilization, community storage, consolidations by districts, and nationalization of the coal mines, all of which will tend automatically and unavoidably to increase the price of coal. His remedies or suggestions were:

(1) The inability of the carriers to transport the needed coal should be removed by lifting from the carriers the cause of their incapacity—too much regulation.

(2) The coal operators should so stagger the expiration dates of wage contracts that nationwide strikes are thereby made impossible. If in violation of contracts a nationwide strike is called depriving thereby the people of fuel, the statutes governing conspiracy should be invoked.

(3) A part of the coal field should be kept perpetually free of union domination to serve as a buffer district between the labor unions and the nation's fuel supply.

(4) The railways should be relieved of all necessity to serve any coal mines until after nine month's notice is given that such service is required.

(5) Wage contracts between miners and operators should be cancelled if the workers refuse to employ labor-saving and cost-cutting machinery.

"If the effect of these recommendations," said Mr. Cushing, "should be to abridge the activities of the Department of Labor; abolish the bureau of mediation and conciliation; and prevent in future the appointment of commissions to meddle with wage settlement, I should find in those occurrences no occasion to modify these suggestions."

Herbert Hoover, Secretary of Commerce, discussed the economic measures needed for "holding on to prosperity" in an address on Tuesday night. Dealing with the present situation, Secretary Hoover praised caution, stressed the need for confidence and courage as well, and marked emphatically the difference between caution and timidity.

The broader and deeper essentials involved in the planning of commerce and industry to keep the nation permanently prosperous constituted the major theme of the address.

He cited the increase in efficiency of production of from 10 to 15 per cent per capita since the period immediately preceding the war as one important phase of the necessity for new standards of business thought. A selection of industries furnishing commodities raising the plane of the

average citizen's comfort and convenience of life in the past decade shows a growth of 60 per cent.

Speaking on coal and transportation he said, "One of the great wastes in our economic machine is the shortage of transportation. It is the most profound and far-reaching deterrent upon our growth. It imposes great costs upon production. I need not point out to you that the periodic car shortage in its real meaning of insufficient tracks and terminals, as well as rolling stock, imposes intermittent stoppages of our industries and intermittent strictures in the law of supply and demand, influences price levels and creates local famines and gluts.

"It imposes burdens upon us which I believe every year create commercial losses equal to the entire capital cost of bringing the transportation system up to national need. It would be easy to demonstrate that in the additional price of coal due to insufficient transportation during the past year we have paid more than the equivalent of a 50 per cent increase in freight rate on coal.

"The causes of shortage are not far to seek. While the war contributed much delay and demoralization, the continued strangulation of railroad finances alone, before enactment of the present transportation law, could have brought us only one result. Nor is this a criticism of the railways, for they have grown in detailed working efficiency with the rest of the country. In a decade they have increased the movement of goods by 15 per cent with an increase of 3 per cent in personnel. Moreover the managers are showing great faith and courage in the undertaking of a large program of expansion. . . .

"There is a matter of immediate importance in which the commercial public can be of the utmost assistance in transportation and at once. Pending a large amount of betterments the railways are overtaxed to handle the vast volume of commodities we are producing and consuming even to-day. The continuance of our prosperity depends upon their handling the full load. With the continuation of business volume their burden will be even greater next fall than ever before. Therefore, a great service can be given if every local Chamber will definitely organize to cooperate with every local railway official toward this end. Particularly can the whole community assist if it stocks its coal between now and September so as to relieve the fall and winter traffic.

"There is another direction in which we have great opportunity to improve national economy. That is in the better functioning of our coal industry. If we can reduce the intermittence of operation of the mines and secure their more even seasonal production we shall by eliminating one-third of the capital and labor involved, accomplish three great things of industrial progress—give greater stability to the industry, give better conditions of labor and reduced costs to the consumer."

Operators Submit Brief on Outlaw Strikes In Anthracite Fields

On May 1 the anthracite operators submitted to the U. S. Coal Commission a brief on Outlaw Strikes in the Anthracite Fields, summarizing suspensions called in violation of agreement to submit grievances to established agencies for conciliation and arbitration.

For more than twenty years the anthracite industry has been working under union agreements with established machinery for conciliation and arbitration, states the brief. That machinery now provides for committees at each mine to adjust matters which are not settled with the foreman; a Board of Conciliation, composed of three operators and the presidents of the three district unions to adjust matters not settled in the colliery; and an umpire, who sits as supreme arbiter in cases where the board cannot agree. In spite of the fact that this machinery, based on agreement between the parties, is in full swing, and operates as a fair safeguard against unfair treatment of the miners, outlaw strikes have grown to enormous proportions.

"The total magnitude of these outlaw strikes, which are violations of agreement and exclusive of general strikes, paints a picture of chaotic conditions which it is our indisputable duty to present.

"In 1919 35,139 different men engaged in outlaw strikes and 235,553 man-days were lost. The lost output was about 377,000 tons, of the value of over $2,250,000.

"In 1920 96,840 different men were idle on outlaw strikes and the man-days lost were 1,815,000. The lost output was about 3,356,000 tons, of the value of over $20,000,000.

"In 1921 52,117 different men engaged in outlaw strikes and the total man-days lost were 823,279. The tonnage lost was 1,372,000, of the value of over $8,600,000.

"One company alone endured about 70 outlaw strikes in one year and nine months, and during two months in 1920 suffered a tonnage loss on such account of over 850,000 of the value of over $5,000,000. When the Wilson Anthracite Coal Commission rendered its award in August, 1920, giving the men an increase of 17 per cent, over half of the industry was tied up about two weeks in a so-called 'vacation strike' as a protest against the award.

"As one views this accumulation of economic waste in an organized industry operating under union agreements with facilities for conciliation and arbitration and the preposterous and frivolous character of so many of these outlaw strikes, there is reason to believe that there is no other industry where this evil has reached such extremes and where union discipline and responsibility has so completely collapsed.

"The difficulty does not lie with the machinery for adjustment which has been repeatedly readopted by the parties but in the irresponsible power of the United Mine Workers which, as in the case of all human institutions, inevitably leads to arbitrary action. Uncurbed human power seldom stops at the portals of justice. The remedy does not lie in discarding or emasculating this organization but in devising some adequate means whereby responsibility, and submission to the machinery for conciliation and arbitration, can be maintained. In order to approach the remedy, which will be the subject of one of our late papers, it is first necessary to review the work of the Board of Conciliation and the general subject of outlaw strikes."

After giving details of button strikes, holidays and other forms of outlaw strikes Walter Gordon Merritt, counsel for the anthracite operators, concludes:

"The underlying cause of this chaotic condition is a moral attitude well exemplified by the boastful and triumphant statement of one of the district presidents at the close of the 1922 strike, when he said:

" 'From time to time as the fight went on, the operators changed their arbitration proposals and dressed them up in many disguises, but the mine workers refused to become parties to any arbitration or approach to arbitration. We refused arbitration from the President of the United States notwithstanding that all the pressure of the government was back of that proposal.'

"Countless victories over the operators in minor matters and continued repression of criticism and insubordination on the part of the rank and file of union membership, have produced an autocratic machine with little or no regard for the rights of others. Numerous demands won through infliction of great financial and economic losses for which the unions have never been made answerable, with a resulting disregard of legal and moral responsibility, finally reached their consummation in this boasted rejection of the proposals of the Chief Executive of the nation, who desired only to protect the public from privations.

"No moral or legal restraint having been operative, these organizations, placed in the strong strategic position because of steady employment of the miners at high wages, have become imbued with a sense of power which heedlessly violates contracts and exults over resistance to the proposals of the chosen representative of our people. To reverse this condition, to encourage democratic administration of union affairs, and to impose a sense of responsibility, some system must be devised which will justly bring home to these organizations the burden of their wrongdoing. The operators have in mind a definite proposal to meet this problem and will submit it to the commission as soon as their papers diagnosing the situation have been completed and filed."

Commerce Commission Begins Hearing on Complaint of Dock Operators for Adjustment of Illinois Rates

Will coal rates into the Northwest be changed this summer? The question arose during the great rate battle in the Interstate Commerce Commission hearings in Minneapolis and St. Paul, Minn., which started May 2 and were scheduled to end May 8, and in which the Northwest Dock Operators' Association hoped to prove that Illinois rail rates into the Northwest were unreasonably low. No official statement from the commission was made on the point, but the impression became firmly fixed in many minds that a decision will be made within two months. In the hearings the dock interests asserted that present rates debar dock coal from much territory it had learned to regard as its natural market. Illinois replied that what the docks really want is a fabric of rates that will continue the dock monopoly on Northwest trade.

Five complaints were on the list for hearing. The first was I. C. C. Docket 14476, a complaint of the Northwest Dock Operators' Association attacking past adjustments of rates from Illinois, more particularly southern Illinois, to points in Iowa, Minnesota and North and South Dakota as being unreasonable. The second case was I. C. C. Docket 14622, a complaint of the Board of Railroad Commissioners of South Dakota seeking rates on fine coal to South Dakota destinations. The third was I. C. C. Docket 14533, a complaint of the Traffic Bureau of the Sioux City (Ia.) Chamber of Commerce seeking changes in rates from Duluth and from Illinois to that city. The fourth was I. C. C. Docket 14477, in which the C. Reiss Coal Co. asks that the Holmes and Hallowell scale be applied to coal from Illinois to Wisconsin. The last was I.C.C. Docket 14142, a complaint of the Illinois Coal Traffic Bureau on inequalities in rates to local stations in Wisconsin from Lake Michigan docks and from the northern Illinois field.

It was evident on the first day that the commission expects to make as quick a job of the case as is consistent with careful consideration of evidence. C. I. Kephart, examiner for the commission, at the outset told the assembled lawyers, traffic men and lay representatives that the briefs and oral argument must all be in and the hearing finished by May 8, and that on June 8 final communications must be in the commission's hands.

On the first day the dock case presentation was completed—after some seesawing. Wayne Ellis, secretary of the Northwest Dock Operators' Association, under questioning by Attorney Frank Lyon, for the association, declared early in his testimony that the interests he represented did not care whether the commission raised rail rates on coal from Illinois or lowered rail and lake rates so long as an equalization to Northwest points was obtained. What the dock men want, he said, is an extension of the Holmes and Hallowell scale. This brought a stiff rejoinder from F. S. Keiser, traffic manager for the Duluth Chamber of Commerce, who protested that the dock men ought to have the interests of the consumers of the Northwest closer to heart than that. Lower coal rates is what the people of the Northwest want and need, he insisted. After a recess the Ellis statement was withdrawn and the dock association was recorded as not favoring a change that would add to the ultimate cost of coal in the Northwest.

Most of the testimony for the dock association in the first complaint—I. C. C. Docket 14476—was contained in a thick pamphlet prepared for the commission and filed as an exhibit. This and the bulk of other evidence introduced by the complainant dock interests made an exhaustive argument to show that present rail rates from Midwestern coal fields to points in Iowa, Minnesota and North and South Dakota are unreasonably low as compared with rates from Duluth and West Superior, that this enables rail competitors practically to deprive the upper Lake docks of their natural and normal business, thus endangering an investment of $25,000,000 or more in dock facilities; that the long haul of empty cars from the Northwest back to Illinois mines is a handicap to transportation and ought to be discouraged, and that the storage service the docks are able to perform for the Northwest ought to be encouraged. The case has been presented in most of the principal details in the press during the past month or so.

In 1917 the Interstate Commerce Commission increased freight rates 15c. per ton on the rail hauls of rail-lake-rail coal. Thus the total addition was 30c. on lake coal whereas the same advance added but 15c. to the Illinois rate. In further orders of the commission since then total advances on coal going into the Northwest by rail and lake have been $1.74, and on Illinois only $1.17. This difference of 57c. to the advantage of the Illinois shippers is the cause of the present complaint of the dock interests.

The dock complaint cites the steady decrease in coal handled by the docks and the steady increase of shipments of Illinois coal into the Northwest as proof that rates are so badly out of line in favor of Illinois that fair competition is disturbed. In 1913 lake shipments to Duluth totaled 11,000,000 tons of Eastern coal and the increase by years had been averaging 10 per cent. But in 1921 the total was only 7,500,000 tons, of which 3,750,000 are said to have been carried over after the winter season. In 1922 the total was about 6,500,000 tons and dock men prophesied the 1923 total would be less. The Illinois answer to this was that the drop in dock business was partly due to the decrease in total production of the country during the past two years and partly to the fact that the pool system of shipping Eastern coal to the Northwest has lowered the quality of dock coal.

Says Dock Interests Seek Monopoly

Fred H. Harwood, traffic manager for the Illinois Coal Traffic Bureau, in presenting the arguments for the Illinois and Indiana operators, declared that the petition for an adjustment of rates clearly shows that the dock interests are seeking to reduce the amount of coal coming into the Northwest and thereby set up a monopoly. He presented testimony to prove his claims and showed that rates from Illinois and Indiana are even too high now to give the Middle Western producers the opportunity for competition in the Northwest they ought to have.

"The members of the Illinois Coal Traffic Bureau are favorable to and consider that rates on bituminous coal should be made and maintained on the group basis of adjustment, both as to origin and destination, except there are situations where this might be modified to fit conditions as to short-haul points, such situations, however, to take into account all conditions," he said.

Mr. Harwood said that rates on coal from Illinois and Indiana to the Northwest have already been advanced during the last 10 years, while rates on Eastern coal to the docks have remained unchanged. This, he declared, was a discrimination and hurt Illinois and Indiana competition in the North.

The rail defendants expressed surprise that the dock case was put in so briefly—with such lack of detail—and they suggested an elaborate hearing was a waste of time. The dock men's case was made up largely of records and was based upon the theory of rate making adopted by the commission in its own decisions on cement rates. They said the records themselves furnished case enough to convince anybody that rail charges from the docks inland are discriminatory.

J. W. Goodman, for the Commercial Club of Grand Forks, N. D., said dock rates to that city were too high as compared with Montana and Wyoming rates. This started an argument as to whether the dock interests want to reopen Western rates which have just been established after exhaustive study. J. L. Browne, of Sioux City, Iowa, said that rates from the docks to Sioux City are too high and that Illinois rates to the Northwest are so inequitable that variations of 300 miles make no difference in charges. He favored distance rates. Belleville (Ill.) operators inter-

vened in the Sioux City case, asking that the Standard mining district get the same rates to Sioux City as does the Springfield (Ill.) district, though it is 80 miles farther away. Commissioner Kelley, of the South Dakota Railway Board, said that a general revision downward on rates from all points into that state is needed.

On Monday morning the hearing was transferred from the Federal Courts Building to the Minnesota Senate Chamber, in St. Paul. Several intervenors with local interests were heard, urging generally that no increase be made. F. H. Harwood was heard in rebuttal. The Western railroads cut some of the ground from under the dock men's feet Monday afternoon when B. B. Beidelman, of the Great Northern, the carriers' spokesman, opposed any reduction of the Holmes and Hallowell schedule for coal going off the docks. He denied the dock operators' statement that there is a balanced movement of box cars loaded west with coal and east with grain, saying the roads have to haul great numbers of empties from the Twin Cities and elsewhere back to the dock. Public-utility men disclaimed any preference for either dock or Illinois coal rate changes.

Rocky Mountain Fuel Co. Explosion Takes Toll of Ten Lives

An explosion Saturday afternoon, May 5, in the Southwestern Mine of the Rocky Mountain Fuel Co., at Aguilar, Colo., caused the death of ten miners entombed in the workings. The ten bodies were removed from the scene of the disaster at 10 o'clock Sunday morning after continuous work by rescue crews composing eighty men from adjoining mines under the direction of rescue forces from the Bureau of Mines.

Investigation disclosed that the electric current that operates the fan stopped and was off for fifteen or twenty minutes. It was during this interval or when current was restored that the explosion occurred. Three miners managed to escape death by only a narrow margin. If the disaster had not occurred on an idle day sixty miners ordinarily on duty might have been trapped.

Kansas Will Try to Open Its Mines

Out in Kansas they are trying to remedy the coal market and the curse of mine idleness by some kind of official and public action. Just what the method will be may be determined May 10 at a general conference of coal mine operators, mine-union officials, wholesale and retail coal men and railroaders in Topeka. Governor Jonathan Davis called the conference after Ed. T. Hackney, the Governor's special representative, filed a report following his recent study of mine idleness. The investigation was made after the miners had begged the Governor to do something to save their jobs but not to turn the matter over to the hated Kansas Court of Industrial Relations.

In his report Mr. Hackney states that Kansas miners averaged only $1,000 total earnings in 1922 and face a period of suffering if they cannot work this summer. He says railroads are ready right now to do a good job of coal moving; that bins, both domestic and industrial, are empty and that retailers and wholesalers have nothing to do. If these bins are not filled during the summer, he prophesies there will be a panic for coal next autumn, which "will bring joy to the profiteer."

"The miners," says the report, "at this season of the year, when they are not rushed, should be able to produce coal with less slack, that would be suitable for domestic consumption.

"The operators, who say they are taking heavy loss on overhead on idle mines, should reduce the profit on this storage coal to a minimum. The railroad coal-holding companies, to save their industry, should reduce the royalty and rental on storage coal to the minimum. The railroads should utilize their equipment and get tonnage at this slack time, and save the coal industry, with its ever valuable freight revenue tonnage. This would avoid overtaxing their equipment while they are moving the crops and livestock to market."

Union "Soaks" Miners to Limit Output, Says Brief of Anthracite Operators

In spite of the formal agreement between anthracite operators and miners that there shall be no limitation of output, a brief filed May 7 with the U. S. Coal Commission by the anthracite operators asserts that "there is concerted effort on the part of the unions to curtail production by the passage of resolutions fining miners for producing more cars than a specified maximum."

The statement, signed by Walter Gordon Merritt, counsel for the General Policies Committee of Anthracite Operators, says in part:

"Typical cases serve to illustrate the practice. Before the suspension of 1922 it was customary with one company for a miner to load from eight to twelve cars a day. Following the suspension the union imposed a restriction of four to six cars for the various veins, with the result that thereafter the highest output of any man is six cars. One contract miner desiring to make more money and exceeding the union limit in January, 1923, is informed by the union president that he has been fined $25 for loading an excess of seven cars. Finally the fine is reduced in amount and paid, with a warning to the miner that if he again loads more than six cars a day they will 'soak' him.

"Two men are fined in another mine for loading more than two cars of coal a day, and a strike is threatened to enforce collection of the fine. The union president admits the existence of a rule to that effect and declares that any man violating it will be fined. He further states that the reason for the restriction is that the union does not wish the operators to be able to show a large wage earned by individual miners on certain days, and that the union has as much right to fine men for loading too much coal as the law has to fine men for speeding.

"In another case the union demands that the company collect the fine and a strike is ordered because it refuses. The company is punished for refusing to collect a fine imposed on a man doing what the company believes he ought to do.

"Some unions impose a rigid arbitrary limit for all mines and veins regardless of varying conditions. Another local makes the miner forfeit the price of each excess car. Checkweighmen employed by the union to check car weights sometimes are obliged by the union to keep a check on the number of mine cars produced and to report excessive cars to union headquarters.

"When men are asked by the foreman why they do not load more coal, they reply, 'What is the use if we have to pay a fine for loading an extra car.' They frankly state their desire to do more work, but fear union discipline.

"In one mine a normal day's output for a miner will be four cars, but union restrictions keep the production down to not more than three cars, with the result that the breaker has to be shut down on alternate days for lack of an adequate coal supply. A strike is thereupon called to force the breaker to operate every day although its intermittent operation is due to union restrictions on output.

"The direct losses due to outlaw strikes and the economic waste flowing from inefficiency and limited output represents a substantial addition to the total cost of coal production without benefit to anyone."

Coal Bids Sought for Naval Stations

Bids will be opened at noon on May 23 by the Bureau of Supplies and Accounts of the Navy Department, in Washington, for furnishing and delivering about 382,950 gross tons of bituminous coal for the various naval stations from Boston to Pensacola, Fla., and to the Great Lakes Station, Ill. Deliveries are to extend from July 1, 1923, to June 30, 1924. Among the tonnages called for are the following: Boston Navy Yard, 30,000; Brooklyn Navy Yard, 57,500; Philadelphia Navy Yard, 45,000; Annapolis Naval Academy, 35,100; Washington Navy Yard, 50,000; Naval Powder Factory, Indian Head, Md., 33,000; Hampton Roads Naval Base, 22,000, and Norfolk Navy Yard, 45,000.

Coal Commission Has Courage to Say What Is Needed, But Seeks Support of Conflicting Factions

By Paul Wooton
Washington Correspondent of *Coal Age*

There is handwriting on the wall which says that the American people intend to have a coal supply that is constant and which sells at a decent price. The coal-producing and distributing agencies will be well advised if they take note of the public temper and cease their constant warfare and inclination to charge all the traffic will bear before the people take charge of their industry. These are deductions from statements made by Thomas R. Marshall, of the President's Coal Commission.

"There are two broad principles," said Governor Marshall, "which the American people are not going to give up without making a lot of trouble. One is to work when, where, how and for what one pleases. The other is to combine and bargain collectively on wages and working conditions. Those concerned are being requested prayerfully to furnish the means by which these principles can be kept alive and outbreaks or disturbances stopped or be punished."

Continuing, Governor Marshall said: "One of the things much needed in this situation is for the individual citizen to take care of himself. Unless the general government is going into the coal business and is going to make the President a mine boss, the individual citizen must pay attention to his own business and avoid being skinned by coal or other dealers. If the individual will do his part, it will help to rectify matters. Moreover, is there any doubt as to the power of a municipality to issue licenses to those who retail coal? If I were living in Washington and coal costing $8 at the mine was offered for sale at $15, I would hire a hall and start a community coal yard. I would not curse the President. Anyone has the right to pay $1,000 for a spavined horse. Consumers do not have to pay excessive prices if they have backbone enough to take the necessary initiative.

"We need a revival of patriotic impulse in America. There must be a revival of what is fair and square and decent. The law prescribes certain limits but the gospel sets up others. There is need for a new light which will make plainer the duties owed to the people. As far as he can each should forget his legal rights. All concerned should meet the commission in a spirit of conciliation to bring the coal industry to a substantial and continuing basis, insuring a constant supply at a reasonable price, which will allow a fair return on investment and the payment of American standards of wages.

"The commission has nerve enough to tell Congress what ought to be done, but it prefers to have the warring elements back of the plan that is submitted to Congress so that it will not be involved in legislative controversy. In the meantime there may be another coal shortage, another cessation of work and the people may say 'a plague on both your houses'."

Chairman Hammond said that the commission is very much pleased at the settlement reached in the State of Washington. He said the commission could not take much credit in that connection, but that at least it had introduced the contending interests to each other and may have broken the ice for the preliminary discussions. Mr. Hammond again indicated that public hearings are to be resorted to only when the irreconcilable points have been clearly and positively established.

As a result of the commission's suggestion that efforts be concentrated on concrete suggestions as to how peace may be maintained in the industry, it was stated that such views already are reaching the commission. "It would seem," said Dr. George Otis Smith, "that the commission is to have more help and the newspapers less material. It is evident that all are making a new effort to be constructive."

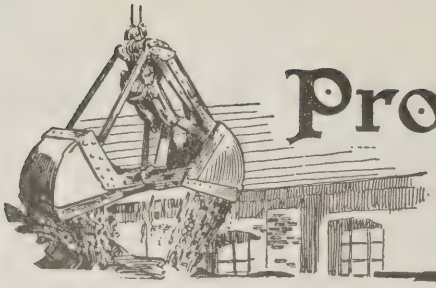
The anthracite operators are to appear soon before the commission in executive session. The commission also expects an early call from John L. Lewis. The returns on the cost questionnaire are being received at a much more rapid rate than those on earnings. Dr. Smith stated that the commission realizes that the earnings questionnaire placed a heavy load on the operator, but that the returns covering large blocks of production are promised in the near future. All returns are being tabulated as rapidly as they are received.

Miners and Operators of Southwest Want Rates on Coal Lowered Materially

Arguments for a reduction of freight rates on coal from the Kansas field to the Missouri River will be heard by the Interstate Commerce Commission in Kansas City, May 17. The hearing will be in answer to a petition by coal operators of the state, based on the claim that rates on steam coal from Illinois to the Missouri River are discriminatory against the Kansas mines. Two attempts have been made by railroads of the affected district to lower rates, but in both instances the new tariffs were suspended by the Interstate Commerce Commission.

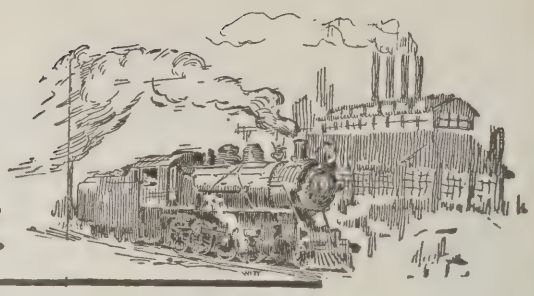
Supporting the operators in their attempt to obtain rate reductions are the miners and business men of Kansas, and the State Public Utilities Commission. It is the first time in many years that operators, miners and the public have been on the same side of the fence in Kansas.

In a request to the Public Utilities Commission to intervene in the hearing, United Mine Workers officials declared that between eight thousand and ten thousand miners in the state are out of work because of lack of market for the product of the mines. The assertions of both the operators and miners concerning conditions in the field are supported by the report of E. T. Hackney, special representative of Governor Davis, who recently investigated conditions.



Discriminatory and unjust rates on coal to the great consuming markets along the Missouri River are protested by the Colorado and New Mexico Coal Operators Association in a complaint filed with the Interstate Commerce Commission April 23, in which a 25-per cent reduction on freight rates is sought to points in Kansas, Nebraska and in South Dakota west of the Missouri River. F. O. Sandstrom is traffic manager for the complainant.

The association declares that business amounting to more than 200,000 tons of coal a year is lost by the operators of Colorado and New Mexico because of excessively high rates. The present rate to most Missouri River markets is $5.26 a ton. The attorneys for the operators hope to show that $4 per ton would be a sufficient charge and would not stifle competition.



Western coal rates were submitted to the Interstate Commerce Commission a year ago when it made an investigation on its own initiative of the rates in Colorado, Wyoming and west to the Pacific coast.

Citing inequalities in rates from various regions, Harry F. Nash said that from Bevier, Mo., to Broken Bow, Neb., 622 miles, the freight rate on lump coal is $4.01 per ton. From Walsenburg, Colo., to Broken Bow, 440 miles, the rate is $5.27, or $1.26 per ton higher with a 182-mile shorter haul. From Herrin, Ill., to Beatrice, Neb., 642 miles, the freight rate is $4.50 per ton. From Walsenburg, Colo., to Beatrice, 578 miles, the rate is $5.27, or 77c. per ton higher for a 64-mile shorter haul.

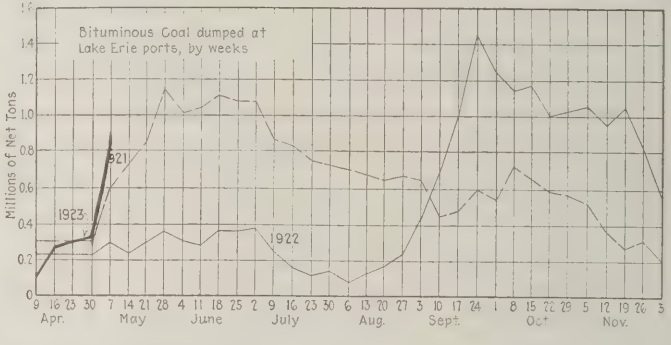
To Superior, Neb., from Kirby, Wyo., a 760-mile haul, he said the rate on slack coal is $3.96 per ton. From Walsenburg, Colo., to Superior, 572 miles, the rate is $4.27 per ton. The haul is 197 miles less but the rate is 31c. per ton higher.

Production and the Market

Weekly Review

May opens auspiciously for the coal trade, both hard and soft. Independent producers of anthracite have a market for domestic sizes as high as $11 and week after week there is hung up a 2,000,000-ton production record. It is true steam sizes are moving much less readily, but that is to be expected. Bituminous-coal production holds around 10,250,000 net tons per week, and prices, though gradually easing off, are well above those a year ago both before and after the strike began. There is a definite movement on foot to build up storage piles of coal this summer in order that when the fall rush hits the railroads there will be no jam caused by essential coal traffic. This drive for summer buying of coal, energetically fostered by the Department of Commerce, is gaining momentum. Thus, although there has been no visible buying movement such as was expected the first week in May, inquiries are numerous and producers and shippers are hopeful.

Production Exceeds that of Active Years

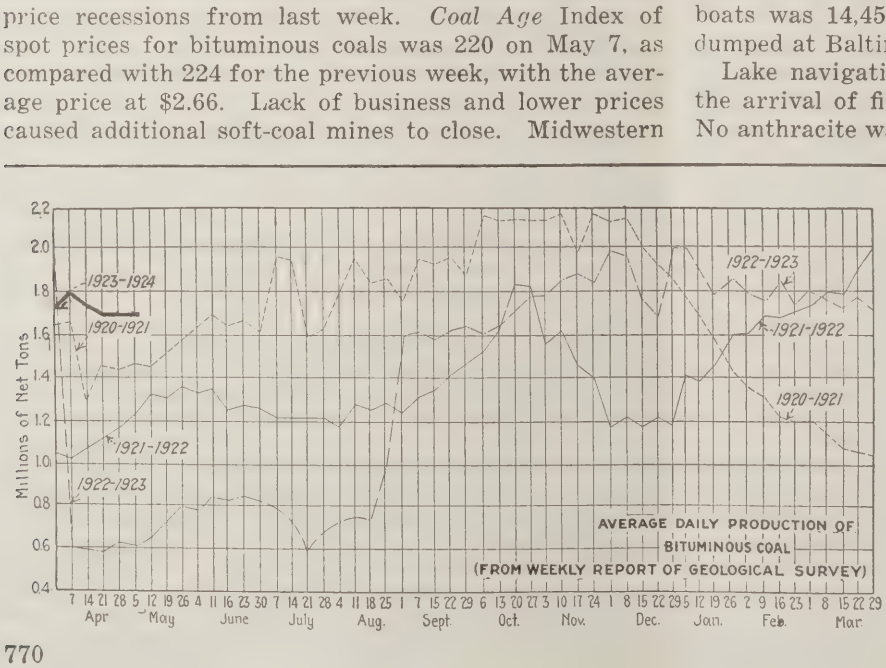


Production of soft coal in the first four months of 1923 was 179,630,000 net tons, about 1 per cent greater than in the corresponding periods of 1917, 1918 and 1920, years of marked business activity, and about 30 per cent more than for the same periods of 1919, 1921 and 1922, years of depression and strikes.

Production of anthracite remains around 2,000,000 tons per week, with 7,850,000 tons as the April output. The output for the first four months of 1923 was 33,718,000 tons, or nearly 55 per cent more than in the corresponding period of 1922.

Nearly all coal with the exception of Standard Illinois and Fourth and Fifth Vein Indiana show small price recessions from last week. *Coal Age* Index of spot prices for bituminous coals was 220 on May 7, as compared with 224 for the previous week, with the average price at $2.66. Lack of business and lower prices caused additional soft-coal mines to close. Midwestern coals are at a low point. There is a lack of active spot demand in central Pennsylvania.

Railroads and utility corporations are the heaviest buyers, taking on good sized tonnages at current prices. Bids received last week by the U. S. Shipping Board for furnishing about 2,500 gross tons of either Pool 9 or 71 coal f.a.s. New York harbor brought tenders ranging from $5.77 to $6.90. A tender of $5.91 was received for furnishing 1,700 tons of similar coal t.i.b. Philadelphia. The New York Custom House bought 400 gross tons of Pool 11 alongside at $4.25, plainly distress coal since not characteristic of the market.



The export market remains quiet, the only feature being a reported inquiry involving about 40,000 tons of

Southern coal. Some chartering of vessels on old business was reported.

During April thirty-five vessels left Baltimore carrying 218,185 tons of cargo coal and thirteen boats carried 66,419 tons of cargo coke. Bunker coal on foreign trade boats was 14,459 tons, making the total coal and coke dumped at Baltimore in April 299,063 tons.

Lake navigation into Duluth opened on May 5 with the arrival of fifteen boats containing bituminous coal. No anthracite was received, although the situation there

Estimates of Production

(Net Tons)

	1922	1923
BITUMINOUS		
April 14	3,656,000	10,401,000
April 21 (*b*)	3,575,000	10,223,000
April 28 (*a*)	4,175,000	10,235,000
Daily average	696,000	1,706,000
Calendar year	144,529,000	179,630,000
Daily av. cal. year	1,438,000	1,783,000
ANTHRACITE		
April 14	6,000	2,067,000
April 21	6,000	2,065,000

(*a*) Subject to revision. (*b*) Revised from last report.

regarding hard coal is serious. Heavy ice is reported in other sections, notably at the "Soo" and difficulty is expected in getting boats through. Many loaded vessels are waiting at the lower Lake ports for the ice to break before venturing outward.

"The production of soft coal during the last week of April," says the Geological Survey, "was practically the same as in the week preceding. The total output was estimated at 10,235,000 net tons against 10,223,000 tons the week before, and 4,175,000 tons in the corresponding week in 1922. Preliminary reports of cars loaded in the week April 30-May 5 indicate declining production. This was due to the partial observance of the May Day holiday at some mines. Loadings on that day totaled 27,359 cars against an average of about 31,000 on recent Tuesdays."

Dumpings at Hampton Roads for all accounts during the week ended May 3 was 355,271 net tons, as compared with 323,855 net tons the week previous.

Demand for the domestic sizes of anthracite continues undiminished. Producers are heavily booked and some are refusing further orders. There are many buyers from Canada in the mining fields ready to pick up any spot domestic coals that may be available.

Midwest Trade Still Slow

Trading in almost all midwestern coals in Chicago remains at a low point. The May 1 boost in prices of domestic sizes of southern Illinois coal had the expected effect: A few more mines shut down for lack of business. But this further reduction of the fuel supply of the region did not hoist the rock bottom price of screenings. Steam buyers take what is offered at the low quotations and placidly decline everything else. Railroads have begun to buy some lump because those mines which are running must have a place to put sluggish domestic sizes.

Coal equipment from some of the central western lines is trickling eastward into service between Kentucky and the Lakes. There car supply has been improving over the past week with the swell in Lake traffic.

St. Louis Market Is Soft

Down around St. Louis steam demand has shown a slight pick-up. Carload screenings are moving a degree easier though the trade in steam coal in small lots is as dead

*Net tons, f.o.b. mines †Advances over previous week shown in **heavy type**, declines in *italics*.

Coal Age Index 220, Week of May 7, 1923. Average spot price for same period $2.66. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

as ever. The demand for everything else in that market is light, indeed. Anthracite and smokeless are beginning to go into storage in a small way, however. Mt. Olive and Standard are slow in this direction. Retail prices did not increase on May 1 when the field price of southern Illinois domestic advanced from $3.85 to $4.10. Evidently there is a good deal of coal on hand at April prices to be cleaned up before any changes are made to householders.

Kentucky Gets Busy

There has been some fair movement of coal from eastern Kentucky the past week, due to better car supply. It is reported that the Hazard field established a one-day loading record on April 25, when a good car supply was set in. Prepared sizes are in better demand as a result of Northern stocking movement, but increased production of prepared is making for a weaker market on screenings, in spite of fair industrial consumption.

At Duluth only screenings are left on the docks. Dock men assert that all other coal has already been contracted for. With this condition dealers and consumers are holding off buying, waiting for whatever change in price the new coal may bring.

According to the most authoritative reports obtainable the Youghiogheny and Hocking coal will reach Duluth at $675@$7. This is $1.50 lower than the last price and is $2 lower than the price two months ago. Run of pile, it is said, will open up from $6 to $6.25, and screenings will be between $4.50 and $4.75. Screenings are now quoted at $4, but those offered contain much old stock that is damaged. There has been no price yet on Pocahontas lump, but mine run will probably open up from $7.50 to $7.75. The present price is $8.50. It is felt that these lower prices will give the docks here a better chance to compete with coal brought all rail from southern Illinois all rail, but dock men hold to their position that unless some adjustment is made not more than half the usual supply of coal will be brought up this year.

There has been no anthracite loaded out of lower Lake ports as yet. The situation at the Head-of-the Lakes is serious. There is no hard coal left on the docks, and public restaurants and other consumers who must have coal for their stoves are bringing some in all-rail.

Beginning with May 1 at Milwaukee a radical reduction was made on all bituminous coal, the cut varying from $1.25 to $3 per ton. Anthracite is held unchanged in price. The wholesale price of Pocahontas screened was advanced 25c. per ton. Coke was cut $1.10 per ton on all sizes.

West Drones Along

Nothing is disturbing the calm of the Western coal trade just now except feverish activity to find markets on the part of those companies whose mines are still running three or four days a week. In the Kansas, Oklahoma, and Arkansas region, union officials estimate between 8,000 and 10,000 men are idle. In Colorado May prices to encourage storing have put a little coal in cellars but the market is dull. Best bituminous lump is selling for $5.15. Slack ranges from $1.75 to $2.50. Lignite lump is offered at $2.75. Another landslide has choked tunnel No. 52 on the Moffat road, thus shutting Routt County coal out of the Denver market for a week or more.

In Utah there is a movement to eliminate certain "superfluous" sizes. Two or three of the biggest operators have announced new low prices on the four sizes they expect to make in the future. This circular reads: Lump, $4.50; domestic lump, $4; stove, $4, and slack $1.75. This is a decrease in mine price, but retailers have not yet dropped their price to consumers.

Ohio Markets in Doldrums

Quality of coal offered is playing an important part in the Cincinnati market. Houses with the grades wanted by the trade are getting what little business there is to be had. There was a slight note of weakness running through the smokeless trade. At Columbus the lateness of the Lake season put a damper on the trade. Steam buyers are holding off and while some are putting in a supply of coal others are playing a waiting game. Utilities and railroads are the best buyers of steam coals, while iron and steel plants are showing a tendency to come into the market. Domestic trade shows some signs of revival and dealers are looking for high-grade coals. Although a fair tonnage of Pocahontas is coming into this market, it is scarce. Contract making continues slow in the eastern Ohio field with commercial steam-coal users, while operators and jobbers are indifferent because of the low prices prevailing in the spot market.

The West Virginia market reports a growing demand for low-volatile coal with prices steadily advancing, smokeless mine-run ranging $3.75@$4.25, f.o.b. mine. There has been little demand in West Virginia for high-volatile mine-run.

There has been a further curtailment in production of high-grade gas coal in the Pittsburgh district because producers were not able to get in the spot market what they considered the real value for their product. The railroads. and line consumers are well supplied with their contract coals, resulting in spot trading being light. Business at Buffalo is slow.

Few Developments in New England Market

The market in New England drags along with few developments. A relatively small tonnage of central Pennsylvania coal that was placed during the week netted very low prices, about as low as producers could be expected to

operate on the present wage scale. The territory has been combed over by sales agents to such extent that buyers are reluctant to buy more than small lots. Each week sees even the choicest grades on an easier price basis and some shippers are willing to extend delivery through the summer on present spot quotations. There is little comprehensive business in sight, and the trade is settling down to what promises to be a dull season.

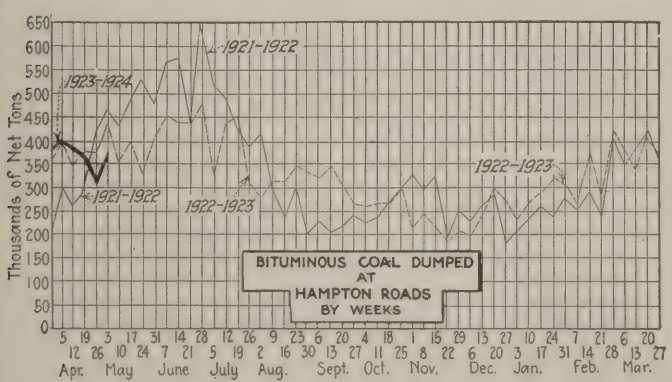
At Hampton Roads there is ample coal on hand for all requirements. Current demand coastwise is light, but there are indications that Pocahontas and New River will be held on higher levels than a year ago.

For inland distribution at Boston, Providence and Portland the best grades continue to offer at $8.25 per gross ton on cars, with seconds at $8 or less. Only moderate tonnages are available, for shippers without their own rehandling facilities are disposed not to risk sending coal forward unsold.

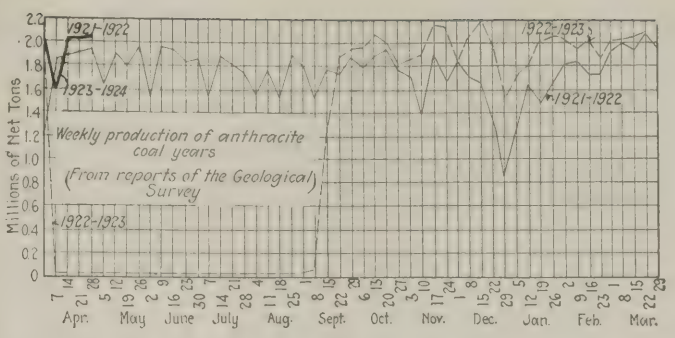
Discriminating buyers near tidewater who last year bought Hampton Roads coals are somewhat puzzled this year to know whether to wait for reduced prices on Pocahontas and New River or to accept deliveries all-rail from central Pennsylvania at current quotations which at present are somewhat more favorable to the purchaser.

A small tonnage of Pennsylvania grades is coming forward by water from Philadelphia, but it is for the most part destined to shoal-water points where Hampton Roads rates of freight are not competitive. Railroad fuel also is being shipped from Philadelphia as well as from Baltimore from usual sources on season contracts. Fairmont coals are being offered at prices well down to $2 per net ton at the mines.

Trade at New York Optimistic



There is considerable optimism among the trade at New York and an active summer with higher prices is anticipated. Conditions at tidewater were weaker. There were 3,994 cars at the local piers on May 4, and some sales at low prices were reported. Many inquiries were received and some shippers contended the situation was in better shape generally than for the past few weeks. Buying was slow at Philadelphia.



The market at Baltimore was slow. Prices for last week show a slight decline. Wagon mines and small operations in the Alabama field are beginning to feel the pinch of the limited demand for steam coal.

The first cargoes of coal arrived at Lake Michigan and Lake Superior docks last week in spite of an ice crush blown in by the wind above the "Soo" in Lake Superior. By the end of the week 500,000 tons had reached Milwaukee and vessels were putting into the Duluth harbor. However, considerable ice continues in the upper parts of the Lakes and it is not expected the season will fully open for at least another week. Meanwhile shippers are picking up odd lots at bargain prices. During the week ended May 7 there were dumped 788,227 tons of cargo coal and 28,365 tons of fuel coal, making the dumpings for the season 1,005,556 tons of cargo coal and 70,752 tons of fuel coal.

Consumers Press for Domestic Anthracite

Consumers continue to press retail dealers for their winter supply of anthracite domestic sizes, with the result that scarcely any of the dealers have been able to start filling their own bins. All of the domestic coals move

quickly although in the New York market egg and stove are in heaviest demand.

"Well-sustained activity marked the reports of anthracite shipments in the week ended April 28," says the Geological Survey, "and for the eighth consecutive week, excluding only the week of the Eight-Hour Day holiday, the output passed the two-million ton mark. Reports from the anthracite carriers show that 40,458 cars were loaded during the week. On this basis it is estimated that the total output was 2,116,000 net tons, including mine fuel, sales to the local trade, and dredge and washery output. This was an increase over the figure for the preceding week of 51,000 tons. In the corresponding week of 1922 there was practically no production of anthracite owing to the miner's strike.

Beehive Coke Production Recedes

The production of beehive coke in the week ended April 28 is estimated at 424,000 net tons, according to the Geological Survey report, a decrease of about 13,000 tons from that of the week before. The decrease, says the report, occurred in Pennsylvania and Ohio. The cumulative output of beehive coke for the year to date is placed at 6,419,000 tons, as compared with 2,305,900 net tons in 1922, 2,850,000 net tons in 1921, 7,374,000 net tons in 1920 and 7,403,000 net tons in 1919.

Foreign Market And Export News

British Coal Output Again Exceeds Record

The mines of Great Britain continued their record breaking production. During the week ended April 21 the output was officially reported as 5,825,000 tons according to a cable to *Coal Age*. This was 48,000 tons more than the output for the previous week and a new high record for the year, as well as topping all weekly production figures for 1922.

British Board of Trade statistics received by the Bankers Trust Co. of New York place the production for the first three months of 1923 at 71,042,500 tons, as compared with 62,201,700 tons in the corresponding period of 1922, and also 2,000,000 tons greater than the production for the final three months of 1922.

It is also reported that several contracts have been made in the South Wales market for South America deliveries during the second half of 1923 and that Germany has been freely placing orders for July-September delivery at less than current prices on some coals.

Quotations eased slightly last week. Congestion at the ports was said to have been slightly reduced during the past couple of weeks and it is expected to disappear entirely soon.

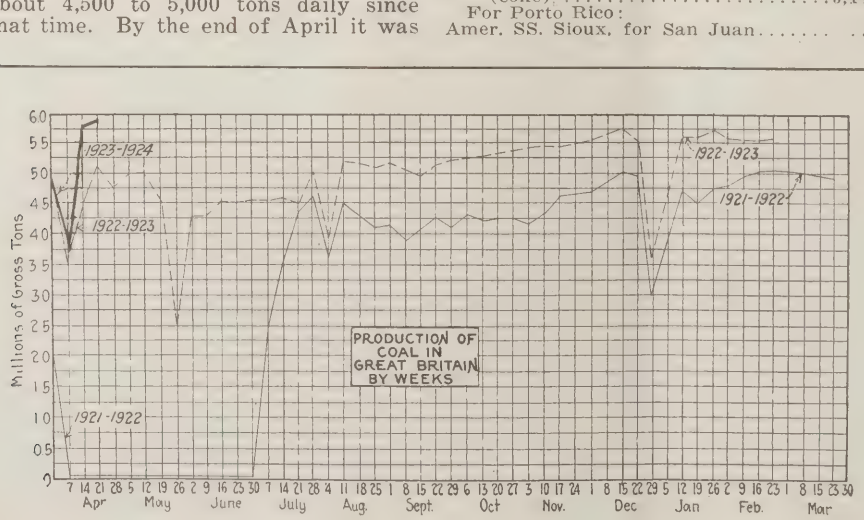
French Coal Situation Easier

The settlement of the Lorraine miners' strike somewhat eased the situation as regards French industrial coals.

Reconstruction of the devastated colleries continues uninterrupted and production is steadily increasing. During March the Lens Co. produced about 100,000 tons and the Couttieries Co. about 150,000 tons.

Efforts made by the French authorities to increase the deliveries of Ruhr coke to French blast-furnaces met with some success. During the first sixteen days of April, 33,400 tons of coke went to France through the Ehrang sorting station. Increased shipments are reported since then, the Societe des Cokes de Hauts-Fourneaux receiving about 4,500 to 5,000 tons daily since that time. By the end of April it was hoped that 9,000 to 10,000 tons of coke would be loaded daily from the stocks seized in the Ruhr, 10 per cent going to Belgium and 90 per cent to France. It is estimated that the coke in storage in the Ruhr district aggregate about 900,000 tons and coal about 1,800,000 tons, but the measures taken by French authorities for seizing part of these tonnages only apply to 500,000 tons of coke and 400,000 tons of coal. On April 21 it was said that 10,370 tons of coke and 5,090 tons of coal were shipped from the storage piles.

The first shipments of American coke have arrived at Antwerp and Dunkirk. The percentage of dust and small coke as the result of the long journey and the handlings is said to have been large with the result that the coke will only be usable after being mixed with others.



Export Clearances, Week Ended April 28, 1923.

Stronger Market at Hampton Roads

Business at Hampton Roads was better last week. Though there was less activity at the Norfolk & Western piers, the general trade was brighter.

Export business improved, showing signs of passing the peak of March foreign trade. Coastwise business was lighter, but the bunker trade held firm. The tone of the market was strong, and the outlook very promising.

Prices of domestic coal were reduced, Pocahontas egg coal selling for $12 instead of $14, and run of mine selling for $9 instead of $11. Anthracite dropped from $17 to $16 temporarily.

Absence of contracts was one of the features of the market, but the trade was looking forward to railroad contracts which are expected to be let June 1.

News Items From Field and Trade

ILLINOIS

The Bradbury-Scullin Mining Co., a new concern at Herrin, has just acquired the Prosperity Mine, near Carterville, and will operate the property in addition to the Lady Lucky Mine No. 1, which was taken over by the company some time ago. The company was recently formed by a group of Williamson County men headed by the two whose names the company bears. **L. C. Meid**, of St. Louis, recently joined the company as head salesman.

The Paradise Coal & Coke Co. announces that its mine at Paradise will be idle for a period of four weeks or longer. During the time the plant is shut down, repairs will be made in and around the mine, including retimbering the shaft and making changes in other parts of the property.

The strike of linemen, electricians and construction men of the Central Illinois Public Service Co., **has been settled.** The company, which furnishes power for over 75 mines in the district, has had its power supply curtailed for six weeks or more as a result of the strike. Many mines were heavy sufferers to the extent of having to close down and towns and business in general suffered heavy losses and inconveniences.

The Old Ben Coal Corporation announces the reopening of its Mine No. 15, at Christopher, May 1. This mine was one of five which were shut down by the company several weeks ago for repairs while the market was at its lowest ebb.

The hoisting record of the Bobby Dick mine near Freeman was shattered recently when a total of 2,892 tons of coal was brought to the surface in eight hours. The day's work totaled 1,166 dumps and loaded 62 railroad cars. The mine employs 310 men, 221 of whom are loaders, making **an average of 13 tons per loader** on that day and 9.3 tons per man in the mine.

No. 1 Mine of the **St. Louis & O'Fallon Coal Co.**, the Lenzburg mine of **Columbia Coal Co.** and **Eureka No. 1 Mine** at Marissa have been closed on account of no markets.

Mine No. 1 of the **Jewel Coal & Mining Co.**, at Duquoin, has been closed for an indefinite period. The mine operated by the **Madison Coal Co.** at Tilden, which suspended operations temporarily a few weeks ago, will resume soon.

A contract for extensive improvements, the cost of which will be in the neighborhood of $30,000 on the mine operated by the **West End Coal Co.**, located one mile west of Springfield on the Baltimore & Ohio R.R., has been closed and the mine shut down May 1 to enable the repair work to start, according to an announcement made by the officials of the company. A shaker screen of all steel construction will be installed, together with new conveyors and elevators. The Wisconsin Bridge & Iron Co. is to furnish the structural steel and the Link Belt Co. will furnish all other material. The present structure has been in service since 1903 and while the equipment is still serviceable, the operators of the mine believe it best to install more modern equipment that will meet the demands of an expanding business with greater efficiency.

The **Sheridan Wyoming Coal Co.**, 910 South Michigan Ave., Chicago, is now selling Kathleen coal for the Union Colliery Co. in the Illinois and Wisconsin territory.

Mine No. 6 of the Peabody Coal Co., at Springfield, went after the coal-hoisting record for the district and broke it by 289 tons for eight hours' work one day recently. The 620 men employed in the mine brought a total of 3,122 tons to the surface, sufficient to load sixty-eight railroad cars. The best previous high mark was 2,833 tons.

The following coal companies were incorporated recently: **Colonial Collieries Co.**, 38 South Dearborn St., Chicago; capital, $500,000; incorporators, Thomas J. Mylet, Edward G. Sternberg and Herbert Lanigan. **The Paramount Fuel Co.**, 343 South Dearborn St., Chicago; capital stock, $30,000; incorporators, J. F. O'Malley, Joseph J. Lelivelt and F. W. J. Sexton. **The Chicago Norfolk Western Coal Co.**, 343 South Dearborn St., Chicago; capital, $20,000; incorporators, L. C. Sieber, C. B. Sieber and J. L. Johnson.

W. C. Schroeder has been made vice-president of the Sebastian Coal Co., of Chicago.

INDIANA

Declines ranging from 25c. to $2 a ton in the retail prices of practically every variety of coal were announced recently in spring revisions of quotations by Indianapolis coal dealers. The new prices are intended for quantity buying of coal for use next winter, merchants said. Indiana lump coal dropped 50c. a ton on the top grades, the range being $5.95@6.75, while Indiana egg and Indiana mine run coal dropped $1 a ton to $7.50. Pocahontas mine run is down 50c. to $1.50 a ton to $9, and Pocahontas lump fell $1 to $2.50 to $11. Eastern Kentucky lump and West Virginia lump dropped $1.50 a ton to $9, and cannel declined $1 to $13. New prices of coke are about $1 a ton cheaper. No changes were made in prices of Blossburg smithing and anthracite.

Bids for a year's supply of coal, approximately 150,000 tons, for state institutions **will be opened by the state purchasing committee soon.** Last year the committee bought 84,675 tons of mine-run coal at an average price of $2.60 a ton; 32,300 tons of pea and slack at an average of $2 a ton, and 29,000 tons of egg size at an average of $2.75 a ton. Lower prices for the next year's supply are expected.

Charters were granted recently to the following coal companies: **Williams Coal Co.**, Evansville; capital, $300,000; directors, Robert R. Williams, Joseph Wastjer and William W. Gray. **Midland No. 4 Coal Co.**, Jasonville; capital, $50,000; directors, Roy E. Price, W. F. Ellis and Wilbur S. Hays. **John H. Scott Coal Co., Inc.**, Linton; capital, $5,000; directors, John H. Scott, James D. Scott and John O. Travis.

The Indiana Coal Dealers' Association has under consideration a **proposal to change its name to the Indiana Coal Service Bureau, Inc.**, and to make its service statewide. Statistical information and other data would be provided in a more comprehensive way than at present.

IOWA

Appanoose County in 1922 for the first time in history, led the state in coal production, according to the yearly report of **L. E. Stamm**, secretary of the state board of mine inspectors of Iowa. The county's production was approximately a million tons. Mines in that county employ 3,527 men, the largest number employed in mining in any county in the state. Monroe county, with more than 2,500 miners, followed, while Polk county, third, had a total of approximately 2,000. A total of 13,155 men were engaged in mining in Iowa in 1921 while this number was slightly increased in 1922. Mine accidents in Iowa during 1922 took a toll of eighteen lives. Falls of slate caused twelve of the deaths.

In order **to promote thrift and neatness among its tenants**, the **Madison Coal Corporation**, has announced a list of cash prizes for the best-kept and best-appearing yards of its employees, and another list for the best kept vegetable gardens. The first prize for each contest is $35, the second $30 each, and down to $5, which is the seventh and lowest cash prize offered, a total of $140 for the best kept and best appearing yards and $140 for the best vegetable gardens, or a grand total of $280 in each mining town of the company.

KENTUCKY

News was received April 25 from Madisonville that **workers have again been fired upon as they were leaving the plant of the Pontiac Coal Co.**, near Earlington, where five workers were fired upon from ambush on April 17. The company has offered a reward of $1,000 for arrest and conviction, and county authorities are starting an investigation. These two outbursts at the one plant have been the only ones in the strike field.

Double-tracking of the Louisville & Nashville from Pineville to Harlan, approximately 40 miles, completing the double track of the Cumberland Valley division, from Corbin to the center of the rich southeastern Kentucky coal fields, has been announced. The new double track up the Harlan road will increase the capacity, giving the road sufficient trackage to haul all the coal that can be loaded on the division. Double track beyond Harlan is hardly necessary, in the opinion of coal men, with the road dividing there into the Poor Fork branch, going to Benham and Lynch, the Clover Fork branch and the Martin's Fork branch.

The Ferndale Mining Co., Bell County, capital $3,000, has been chartered by J. M. Lunce and J. C. Knuckles, of Ferndale, and E. A. Smothers, of Pineville.

The Rex Harlan Coal Co., Whitley County, capital $100,000, has been chartered by T. J. Roberts, T. E. Mahan and B. F. Cheely, all of Williamsburg.

The Ellser Coal Co., of Clark, has reduced its capital stock from $125,000 to $100,000.

The fight to prevent an increase in tax assessment from $13,000,000 to $18,600,000 **has been dropped by the officials of Perry County, Ky.**, following conferences with the State Tax Commission, and an agreement to withdraw the injunction suit that was filed. The **county officials have agreed to try to increase assessments for 1923** as directed by the state commission. Most of this increase will fall on the coal interests, as Perry is one of the largest coal counties of the state and hasn't much else to tax. Coal operators had made a hard fight against the increase, and had appeared before the argument.

Judge A. M. J. Cochran, of the Federal Court, Eastern Kentucky division, has set for **hearing on May 21**, at Lexington, the **suit of T. F. Fuller against the F. S. Peabody Coal Syndicate**, the Fordson Coal Co. interests and the Semet Solvay Co. and others, a special session of the court being held to hear the arguments. **Fuller alleges that the lands sold by the Peabody syndicate to Henry Ford** are worth $15,000,000 and that he holds an interest in the property valued at $2,500,000.

The coal mining town of Combs, in Perry County, was fire swept on May 1. The Superior Coal Co. lost a commissary store, while a picture theater and other buildings were burned.

The St. Mohiel Coal Co. of McCreary County, has filed amended articles, increasing capital from $25,000 to $40,000.

Guy H. Sowards, who for the past several years has been with the traffic office of the West Kentucky Coal Bureau, on May 1 became resident manager in charge of the Louisville office of the Southwestern Fuel Co., sales agents for the Black Diamond Coal Co., of Drakesboro. B. A. Word, an independent traffic expert, will look after traffic matters for the West Kentucky Coal Bureau.

The coal mines of **the Hazard field** with a loading of 1,177 cars on April 25 **broke all previous records** for a day's loading on the Eastern Kentucky division of the Louisville & Nashville R.R.

At Jeffersonville, Ind., work of setting up six all steel coal barges from fashioned steel was started recently, the six barges being for the E. T. Slider Co., of New Albany and Louisville, operating yards at both points and towing coal and sand and gravel on the Ohio River.

NEW YORK

H. G. Stenersen has been appointed assistant to the president of the Coal & Iron National Bank of New York. Mr. Stenersen was formerly with the National Bank of Commerce as assistant cashier in charge of business development in the First and Second Federal Reserve districts. In 1917 he was the pioneer in introducing the use of acceptances among New England cotton mills in financing the purchase of cotton.

E. W. Rockafellow, formerly assistant general sales manager of the Western Electric Co., resigned May 1 to accept the office of **vice-president of the National Pole Co.**, of Escanaba, Mich. He will represent the latter company at 220 Broadway, New York City.

W. H. Bradford & Co., Inc., have removed their New York office from 17 East 42nd St. **to the Barrett Building, 40 Rector St.**

OHIO

The Pocahontas-Kanawha Coal Co., established in Dayton, has opened a Cincinnati office with Fred Dunker, formerly sales manager for the Western Coal Co., in charge.

The Republic Iron & Steel Co. has awarded a contract for the construction of **a 60-oven byproduct coke plant** at Youngstown.

The Kearns Coal Co., of Cincinnati, has been incorporated under the Ohio laws with a capital of $200,000. The incorporators are Eugene Buskirk, George M. Kearns, R. H. McCormick, Howard Ragland and P. T. Foley.

The Maple Grove Coal Co., Columbus, has been chartered with a capital of $25,000 to mine and sell coal. Incorporators are: Edward E. Riley, S. C. Longby, S. W. Krumm, Walter Mulby and Charles E. Belcher.

Sealed proposals will be received at the office of the Clerk of the Board of Education, eighth floor, Denton Building, Seventh and Race Streets, Cincinnati, Ohio, until 12 o'clock noon, Monday, May 28, 1923, **for supplying the various public schools in the school district of Cincinnati with coal** in accordance with specifications on file in the office of the Visiting Engineer of said Board of Education, at No. 511 West Court Street.

The Ohio Legislature has passed a bill over the veto of Governor Donahey reimbursing coal producers and shippers for coal furnished various state institutions more than a year ago on contracts which were later declared illegal by the courts. In their appeal to the Legislature the various coal companies contended that they were not a party to the illegality in the contracts and should be paid for the coal furnished. The Legislature saw it that way and passed the bills which were vetoed and later passed over the veto. About $100,000 will be distributed to about a dozen coal companies in Ohio.

The Valley Coal Co. closed its Cincinnati office on May 1.

The Cincinnati Coal Trade Golf Association was recently launched at a meeting of sales representatives, wholesalers and producers at a meeting held at the Highland Country Club and its organization was completed at a further meeting that was held at the Ft. Mitchell Country Club. The association will be modeled along the line of those established in Chicago, Philadelphia and New York.

PENNSYLVANIA

Orders for coal that will keep the mines of the **Bechly Coal Co.**, at Portage, **busy for a year**, have been received by the officials of the company. The company has the assurance of the Pennsylvania R.R. that all assigned cars necessary will be supplied. From 200 to 300 men will be required.

T. Stanton Davis and W. C. Schiffer, both of Ebensburg, **plan to open a mine** near the Chickaree school house, along the William Penn Highway, west of Ebensburg to supply Ebensburg direct with fuel. The mine taps the "B" or Miller seam and Davis and Schiffer control more than one hundred acres. The coal will be hauled over the William Penn highway by truck.

The Jefferson & Clearfield Coal & Iron Co. reports for 1922 a balance for common dividends of $382,521, equal to $25.50 a share on the 15,000 shares outstanding. This compares with a deficit of $153,099 in 1921. On December 31 last the profit and loss surplus stood at $5,867,554, as compared with $5,785,034 on December 31, 1921. At the end of last year current assets were $3,906,144, and current liabilities $1,244,412, leaving net working capital of $2,661,732.

Westmoreland Coal Co. has declared a stock dividend of 33⅓ per cent on the outstanding $7,500,000 capital stock, payable May 15 to stockholders of record April 28, from the undivided profits of the company in capital stock of the company, which was increased at the shareholders' meeting April 4.

A deal was closed last week at Ebensburg, Cambria County, whereby the **Pennsylvania Coal & Coke Corporation becomes the owner of 277 acres of "B" seam coal** located in Barr township. The purchase was made from the Carrolltown Coal Co. The consideration was $520,000. The entire tract is adjacent to the lines of the Pennsylvania R.R.

State charters have been issued recently for the following coal mining companies at Harrisburg: **Blanchard Zanesville Mining Co.**, Pittsburgh, capital, $450,000; treasurer, William Wieman, 426 Fulton Building, Pittsburgh. Incorporators: William G. Blanchard, P. W. Ranier and R. E. Allen, Pittsburgh. **Bowman Coal Co.**, Pittsburgh, $10,000; incorporators, Ralph D. McKee, Avalon, treasurer, Frederick E. Milligan and Elwood B. Hawarth, Jr., Pittsburgh. **Beadling Mining Co.**, Pittsburgh, $20,000; incorporators, Charles E. Kitchen, 3222 Middleton Road, Pittsburgh, treasurer, Vincent R. Beadling, Pittsburgh and John Barufaldi, Morgan. **Windber Fuel Co.**, Windber, $50,000; incorporators: L. L. Faust, Windber, treasurer, L. R. Ashenfelten, Philadelphia, and Fred J. Balch, Springfield, Mass.

The Acme Coal Mining Co. has declared a dividend of 20c. a share, payable June 5 to shareholders of new stock only, of record May 26. Stockholders have been notified that the old stock of $1 par value can be exchanged for stock of $10 par at the Empire Trust Co., New York City.

The Bertha Coal Co. of Pittsburgh, is to have a Roberts and Schaefer preparation and loading plant at its Dinsmore mine.

Slattery Bros., Inc., are making preparations **to open a new mine** in the Schuylkill Valley, east of Port Carbon. Wade M. Reed, consulting mining engineer, will have complete charge of this development work together with this company's Bell Colliery operation.

The Traylor-Dewey Contracting Co., of Allentown, has recently been reincorporated under the name of **The Cement-Gun Contracting Co.** and under that name will continue to specialize in construction and repair by means of the cement-gun and in addition will construct reservoirs and other plain or reinforced concrete structures.

The Pittsburgh office of the central district **of the Cutler-Hammer Mfg. Co.**, Milwaukee, **will move** on May 1 from the Farmers' Bank Building **to Room 950 to 953, Century Building**, located on Seventh Street between Penn Avenue and Duquesne Way. A. G. Pierce is manager of the central district.

The Penn Central Power Co., a subsidiary of the Penn Central Light & Power Co., **has become the owner of 2,600 acres of valuable coal land** in the Broad Top township (Huntingdon County) district. The land was purchased from the Kay Mining Co., of Everett, Bedford County. The Penn Central Power Co. is erecting an immense power plant along the Raystown branch of the Juniata River at Saxton. There is plenty of water for power now, but the company has acquired the coal, which opens out right at the plant, in case fuel is needed to replace the water power at some future time.

A state charter has been issued to the **Conlan-Pace Coal Mining Co.**, Pittston, which has a capital stock of $45,000. Bernard J. Conlan, 42 Church Street, Pittston, is treasurer, and one of the incorporators, the others being Daniel P. Price, Scranton, and Ellen M. Conlan, Pittston.

Bert E. Holifield recently opened an office in the Miners' Bank Building, Wilkes-Barre, and is manufacturers' agent in the anthracite region for the **Chicago Pneumatic Tool Co., the Ironton Engine Co. and the Bennington Scale Co.**

Angus W. Louther, who was assistant to W. H. Kramer, general manager of the Consolidation Coal Co.'s Pennsylvania division, has resigned his place **to accept the managership of the coal mines of the Bethlehem Steel Co.** in West Virginia. He succeeds **Samuel Steinbach**, also formerly of Somerset, who has been promoted to a higher position in the Bethlehem operations in Pennsylvania.

The Anderson Fuel Co., Arrott Building, Pittsburgh, has been organized with G. D. Anderson as manager, to deal in coal and coke. Mr. Anderson, who recently resigned as sales manager for Marvel & Marvel, formerly was with the Poland Coal Co., Reilly-Peabody Fuel Co. and Straub-Atkinson Coal & Coke Co., all of Pittsburgh.

J. H. Klinck has been appointed assistant supervisor of production of the Westinghouse Electric & Manufacturing Co., East Pittsburgh, according to an announcement by R. L. Wilson, works manager. Mr. Klinck has had wide experience in electrical and general engineering and sales work. He is a member of the American Society of Mechanical Engineers, having been active in the organization of both the Birmingham and Washington sections of the society, and is a fellow of the American Institute of Electrical Engineers.

UTAH

By agreement with counsel for both sides in the equity suit of the Quemahoning Creek Coal Co. vs. John Brophy, president of District No. 2, United Mine Workers, and other officers of the union, **the hearing of the temporary injunction** recently granted the coal company by Judge John A. Berkey **will be heard on Friday, May 11.** In the meantime, the preliminary in junction remains in force. The union officials declare the injunction too drastic, but the coal company contends that it is necessary to protect its rights and interests and the welfare of its employes.

The State Securities Commission has **approved the application of the Great Western Coal Mines Co., of which Jack Dempsey is president, to offer for sale $1,500,000 worth of stock.** The stock will be divided into 100,000 shares of preferred at $10 per share and 500,000 shares or common at $1. The company has increased its capital from $3,000,000 to $4,000,000.

Richard L. Bird has relinquished his claim to 160 acres of coal land in Carbon County, between Standardville and Clear Creek, and an application to lease the land has been made by the Great Western Coal Mines Co. In an impending suit for cancellation the Bird holding is alleged by the United States to be unlawful in that "claimant did not file on the lands in good faith."

VIRGINIA

The Seaboard Air Line Ry. is asking bids on something over 1,000,000 tons of coal for distribution over its entire system. Specifications have not been made public, according to announcement at the company's offices at Norfolk.

The Consolidated Coal Co., with headquarters in Roanoke, **has transferred its general offices to Norfolk,** with J. C. Davis in charge. H. E. Halstead, formerly of Hasler & Co. and recently with the Consolidated at Roanoke, will return to Norfolk with the change in offices.

WEST VIRGINIA

Daniel Howard, well known in mining circles in northern West Virginia, in association with D. T. Quinn, J. R. Quinn, Margaret Heitz and Joseph Burr, all of Clarksburg, **has organized Daniel Howard & Co.**, for the production and selling of coal. The principal office of the new enterprise to be at Clarksburg.

The Bowman Fuel Co., which recently acquired large acreages and several mining plants in Monongalia County, has been organized with a capital stock of $150,000. Morgantown is to be the headquarters for this company, the principal stockholders in which are Fred Tropf and Frank L. Bowman, both of Morgantown.

The following West Virginia coal concerns have increased their capital stock: **Logan Thin Vein Coal Co.**, from $50,000 to $100,000, also **changed name to Stollings Island Creek Coal Co.**, and headquarters moved from Logan to Huntington; **Burning Creek Coal Co.**, from $50,000 to $100,000; **Atlantic Smokeless Coal Co.**, from $250,000 to $300,000 The Haywood Coal **Mining Co. has reduced its capital stock** from $150,000 to $37,500.

The Consolidation Coal Products Co., organized under the laws of the state of Delaware and of which H. H. Warfield, of 67 Wall Street, New York City, is secretary, has been granted authority to do business in West Virginia, as has the **Fordson Coal Co.**, chartered under the laws of the state.

The South Fork Coal Co. has changed the location of its principal office from Huntington to the Kanawha Valley Bank Building, Charleston.

The Morrow Coal Co. has just been organized with a total capital stock of $50,000 for the purpose of producing coal in the Mercer County field. The office of this company is at Bluefield. Indentified with the new concern are James F. Morrow, Carl B. Short, A. D. White, W. E. Belcher and T. V. Belcher, all of Bluefield.

The Snake Hill Coal Co., has been organized by Daniel Howard and associates with a view to operating in the Harrison County field, the new company being capitalized at $100,000. Clarksburg is to be the location of the principal office of the company. Associated with Mr. Howard in the new concern are J. R. Quinn, D. T. Quinn, Margaret Heitz and Joseph M. Burr, all of Clarksburg.

The Colcord Coal Co., of Montcoal, is getting picking tables and loading boom equipment for its various mines near Montcoal, W. Va. from Roberts & Schaefer of Chicago.

Lloyd Bailey, who for fifteen years or more has been connected with the Clark Coal & Coke Co., of Fairmont, **has been named as manager of the New England office** of the company and will have his headquarters at Worcester, Mass. The Clark company expects to specialize in coal for public utilities.

Illegal strikes continue in northern West Virginia, the latest one being at the Hutchinson plant of the Consolidation Coal Co., where 140 miners were out for a time dur-

ing the first week of May, when a committee objected to a company official. The belief prevails that many of the strikes which have taken place since April 1 can be attributed to bad feeling which developed during the election of miners' officials. Whatever may be the cause, many of the members of the mine workers' organization are apprehensive of the effect of so many illegal strikes on future negotiations with the operators. Failure of the miners to live up to their contract is creating a good deal of sentiment unfavorable to the union and to collective bargaining in the northern part of the state.

The Kentucky & West Virginia Power Co., at Logan, is installing three Westinghouse new model underfeed stokers to heat three 1,000-hp. Edgemoor boilers to furnish additional steam to generate electric power.

The Elm Grove Mining Co. of Elm Grove, has contracted with the Roberts & Schaefer Co., for a steel tipple which will include picking table screens and loading booms.

The Standard Thacker Coal Co. of Charleston, has reported a capital increase from $25,000 to $150,000.

WASHINGTON, D. C.

A report just made to the Department of the Interior by the Bureau of Mines, which has technical supervision of these operations, discloses that **the royalty value of oil, gas and gasoline produced from operations on government lands in January was $1,074,512.** In comparison with the figures for July, 1922, an increase of 65 per cent is shown. During March two new oil wells were brought in on government lands in Montana. Actual drilling operations were commenced in March in the Cold Bay oil field on government lands in Alaska. On April 1, a total of 10,608 permits for prospecting for oil and gas on government lands had been received from the General Land Office. A total of 334 leases for oil and gas production operations had been issued on the same date. Total net royalties for the production of oil, gas and gasoline on government lands, submitted up to April 1, amounted to $11,684,904. This figure represents operations in the States of Wyoming, California, Montana and Colorado. During March, 37,980 barrels of oil were produced on Naval Petroleum Reserve No. 3 (Teapot Dome), Wyo., on which the royalty barrels amounted to 6,252.74 and the royalty value to $13,175.71. Production for March on government lands in the Winnett, Mont., district amounted to about 166,000 barrels of oil.

Rudolph P. Miller, of New York, has been reappointed representative of the Federated American Engineering Societies on the National Board for Jurisdictional Awards. Mr. Miller's reappointment was officially characterized as evidence of the Federation's confidence in what he has accomplished. His efforts, it was stated, have been "earnest and constructive." Mr. Miller's present term expires in August. **President Mortimer E. Cooley has been authorized to appoint a committee** of the Federation **to look into the subject of basic wage rates.** The committee will report to the Executive Board as to what action, if any, the Board should take toward making such a study. President Cooley has also been authorized **to appoint a delegate to a conference on the problems of the rising cost of construction materials,** providing such a conference is called by Secretary Hoover.

Appointment of four members of the committee to conduct an investigation of the storage of coal is announced by the Federated American Engineering Societies. They are P. F. Walker, dean of engineering, University of Kansas; S. W. Parr, professor of applied chemistry, University of Illinois; H. Foster Bain, Director of the U. S. Bureau of Mines; L. E. Young, Union Light & Power Co., St. Louis. The chairman is W. L. Abbott, chief operating engineer of the Commonwealth Edison Co., Chicago. Four or five additional members of this committee are yet to be selected. Consideration is being given to recommendations by member organizations, and it is probable that the committee will be completed in the near future.

A. W. Ambrose, assistant director of the Bureau of Mines has resigned to take an executive position with the Empire Gas & Fuel Co., chief petroleum subsidiary of Cities Service Co. Mr. Ambrose will direct certain geological, land and lease, and scouting activities for the Empire company.

WISCONSIN

Retail prices on coal and coke at Milwaukee May 1 were: Anthracite—Egg, $15.75; stove, $16.10; nut, $15.95; pea, $14.20; buckwheat, $11.50 (75c. for carrying). Bituminous — Pittsburgh, Hocking and Youghiogheny, $9; pile-run, $8.25; screenings, $7.50; West Virginia screened, $9.75; pile-run, $8.50; screenings, $7.25; Pocahontas screened, $15.25; mine-run, $12.50; screenings, $12; smithing, $13.25; Kanawha gas mine-run, $8.75; Illinois and Indiana screened, $10.50; pile-run, $9.50; screenings, $8.50; coke, large sizes, $14.90; pea and nut, $11.90.

Jobbers of Illinois coal are endeavoring to maintain the advantage gained in Milwaukee during the period of scarcity of Eastern coal. They **have requested the city authorities to modify the specifications** for supplying 65,000 tons of coal to municipal institutions by making them broader and more uniform. They declare that the specifications in past years have been discriminatory in that they favored Eastern coal to the disadvantage of the Western product.

The precarious situation in the coal industry, which hampers the consumer in obtaining fuel and power, was advanced as an **urgent reason for a survey of the water-power resources in Wisconsin,** in a hearing before joint committees of both houses of the Wisconsin legislature. The bill would appropriate $25,000 for the survey.

Julies J. Goetz was appointed **receiver for the Kanawa Fuel Co.,** Milwaukee, April 23, on petition of the Penwell Coal Mining Co., which cited a civil court judgment for $607.77 obtained March 1. The officers of the company are A. S. Austin, president, A. S. Austin, Jr., vice-president, and E. W. Morrison, secretary and treasurer. On the same day John C. Post was named **receiver for the A. S. Austin Sons Co.,** coal dealers, on petition of the Plankinton Packing Co., owners of dock property. The Austins in the latter company are identical with those in the Kanawa company. **The Kanawa company apparently was preparing to reopen its Old Abe mine near DuQuoin., Ill.**

CANADA

The Canadian Collieries (D) Ltd. is doing some diamond drilling near the No. 5 Mine, Cumberland, and **a new seam has been struck** which, it is said, promises to develop into the best coal measure for domestic demand in the Comox field of Vancouver Island. This seam will be worked from the No. 5 shaft, from which a tunnel is being driven through rock in order to escape the heavy expense of a new pit head.

A. R. Braine, representing Tatham Bromage & Co., Ltd., a shipbroking firm of London, England, which sold large quantities of British coal in Canada last summer, has returned to Canada with the view of **establishing a permanent market for the British product.** He has booked some orders from eastern Canadian industrial concerns especially with pulp and paper mills.

Premier E. H. Armstrong recently announced to a delegation of miners that arrangements would be made whereby the **Eastern Trust Co. would operate the Minudie coal mines,** River Hebert, Cumberland County. The company owning the mine went into liquidation owing the miners about $15,000.

Alexander Lewis, M. P., told the members of the Kiwanis Club, of Riverdale, recently that **Nova Scotia coal is being used as far west as Cornwall,** but owing to present shipping facilities it is impossible to compete with the American coal west of that point. The cost of bringing coal from Alberta would be reduced one-third, he said, if larger vessels were able to enter the lakes and bring coal in cargoes of from 10,000 to 15,000 tons from the Head of the Lakes.

A Vancouver syndicate wants the right to mine coal it claims to have struck in the edge of Stanley Park, a natural park near the city, the property of the Dominion Government, that has been leasd to the city for 99 years. The syndicate is promising the City Council it will not disturb the park surface in any way and will completely electrify the mine to avoid the smoke nuisance. The City Attorney is expected to report to the council on the question soon.

The Ontario Cabinet, it is stated, will soon **rescind the various orders issued in connection with the fuel situation,** abolishing the offices of City Fuel Controller and Provincial Fuel Controller, together with all orders controlling the distribution and prices of fuel in the province.

In an address before the Empire Club of Toronto, **Prof. E. S. Moore,** formerly dean of the school of mines, at Pennsylvania State College and now of the University of Toronto, declared that **overcapitalization and overmanning were the twin causes of the troubles which have beset the continent's coal-mining industry** during the past few months. He stated that Canada would be unable to obtain Pennsylvania anthracite longer than twenty-five or thirty years.

Toronto civic authorities are having a shipment of a variety of Welsh anthracite not hitherto tried out sent to the city. It will arrive in May and the price to the city will be $14.50. It is stated that the city can pay overhead expenses and **sell it to the public at $15 per ton.**

Association Activities

Indiana Retail Coal Merchants Association

Honesty on the part of the Indiana retail coal dealers was urged April 25 and 26 at the **state convention of the Indiana Retail Coal Merchants' Association** at Indianapolis, Ind. In a letter from Marshall E. Keig, vice-president of the Consumers' Company, Chicago, Ill., a leader in the retail coal field, was an admission that the probe now being made of fuel conditions by the federal government disclosed that in many sections the fault lies with the retailers. More than 400 members of the association attended the session. Reports giving the belief of the coal dealers that prices will not fall during the remainder of the season were given at the convention. The probable shortage of coal cars and a lack of reserve coal stocks were cited as reasons.

Cincinnati Coal Exchange

A meeting of the Cincinnati Coal Exchange was held at the rooms of the Old Colony Club, on Thursday, May 3, at which President Robert Magee presided. Most of the talk was given over to the discussion of the Fact Finding Commission's questionnaire and the means and methods for filling out the information that is desired. Talks were made by Ernie Howe, of the Pocahontas Fuel Co., R. A. Gillham, of the Campbell Creek Coal Co.; R. A. Volter and George Hill, of the Chesapeake & Virginian Coal Co. Arrangements were concluded for the annual convention of the Michigan-Ohio-Indiana Retail Coal Association, which will be held in Cincinnati on May 23 and 24.

Winding Gulf Operators Association

At the regular quarterly meeting of the Winding Gulf Operators Association, held at White Sulphur Springs the latter part of April, matters of routine and questions affecting the district were given consideration. E. E. White, president of the association, presided over the meeting, which was fairly well attended, and at its conclusion a luncheon was served. Among those in attendance were E. E. White, W. P. Tams, A. J. King, W. B. Beale, A. W. Laing, C. R. Stahl, W. A. Phillips, B. H. English, W. H. Ruby, T. H. Wickham, Fred G. Wood, Enoch Ellison, B. E. Smith, J. B. Nowlin, S. M. Miller, William MacTaggart, S. B. Avis, Albert Belcher, Roy T. Wright, W. Gaston Caperton and L. Eperly. George Wolfe acted as secretary of the meeting.

Obituary

Joseph Oliver, formerly head of the Oliver Coal Co., which he founded at Bokoshe, Okla., died at his home in Louisville, Colo., April 6, 1923, aged 67.

Mr. Oliver was born in Newtown, North Wales, and came to America in 1887. He located first in Arkansas, where for many years he was prominently identified with mining operations. For eight years he was general superintendent of the Prairie Creek Coal Co., of Forth Smith, Ark.

Mr. Oliver later moved to Oklahoma, where he became general superintendent for the Bokoshe Smokeless Coal Co., afterward leasing the mines and forming the Oliver Coal Co., of which he was the head for several years.

During his active life he was prominent in public affairs, taking a leading part in the campaign for good schools and educational advantages in the early days of Oklahoma's statehood. He left a wife, four sons and four daughters.

Publications Received

Saward's Annual for 1923 is at hand. The standard form and contents of this book make it a familiar sight. There is, it appears, more than the usual amount of text matter in this volume, which makes it the more difficult to find the figures for which Saward's Annual and the Coal Trade before it has been chiefly valuable. A book of half the size with statistical contents better arranged would more than double the value of this little book, which after all is the only available statistical annual on coal other than government reports.

Tenth Annual Report of the Secretary of Commerce. Pp. 229; 6x9 in.; tables. Price 25c.

Traffic News

The Southern Pacific R.R. has announced a reduction in coal rates from Utah and Wyoming points to Lone Pine, Cal., to become effective about June 1. This reduction will make it possible for Utah and Wyoming operators to place their coal on the market in competition with coal from other sections of the country.

The Car Service Division of the American Railway Association announces the appointment of **R. W. Edwards** as district manager at Toledo, Ohio, with supervision of the following territory: Michigan, lower peninsula; Indiana, north of line from Michigan City through Wanatah, Fort Wayne and Decatur; Ohio, north of line from Decatur, Ind., through Mansfield and Cortland, Ohio, including cities named.

Rates in effect during federal control from June 25, 1918, on iron ore, coal, coke and limestone **from producing points in Alabama to various blast furnaces in that state were not unreasonable** or unduly prejudicial, according to a decision issued by the Interstate Commerce Commission April 28. The complaint filed by the Alabama Co., and other manufacturers, accordingly was dismissed. While the rates were intrastate, the commission had jurisdiction during the period of federal control, but said that it has no authority to deal with the present rates or to prescribe rates for the future.

In order that they may be able to compete in the Northwest with operators of southern Illinois **coal producers of the southern part of Ohio intend to launch a fight before the Interstate Commerce Commission** meeting in Minneapolis **in an effort to obtain a readjustment of freight charges.** Production in Ohio fields is at a low ebb, railroad men declare. This is due to the fact that Northwestern dock operators are reluctant to enter into contracts until the outcome of the conference has been announced and because the lakes are tied up by ice later this year than they have been for 30 years, it has been asserted. However, no difficulty with the mines is anticipated this summer, the agreement now in effect having a year to run. Before leaving for Minneapolis, W. D. McKinney, secretary of the Southern Ohio Coal Exchange, expressed hope that operators of the state would be granted at least an even break. Under the prevailing rates, he said, southern Illinois producers have a 46c. advantage. Freight charges for Ohio total $3.98 a ton, while those from southern Illinois are $3.47.

With the Virginian and the Norfolk & Western both believed to be knocking at the door of the Logan field there is every **prospect of an impending conflict for rights of way in that field.** That either one road or the other is seeking entrance to Logan territory is the deduction of operators as a result of the proceedings instituted in the Circuit Court of Logan County by the Conley's Creek R.R., asking for the appointment of appraisers to condemn a railroad right of way from Stirrat to Gilbert through the large holdings of the late Devil Anse Hatfield and others.

In an effort to obtain joint car service at its plants near Winding Gulf, W. Va., **the Winding Gulf Colliery has instituted proceedings before the Interstate Commerce Commission.** The company points out in a brief filed in the case that a number of the mines adjacent to those of the Colliery Company have been enjoying and are now enjoying joint car service as between the Chesapeake & Ohio and the Virginian Ry. but that the plants of the complainant have not been accorded such a privilege.

Lower railway rates on coal from Alberta and the maritime provinces were promised by Sir Henry Thornton, president of the Canadian National Railways, in a telegram to Senator J. S. McLennan May 6. The telegram said the railways would quote a rate of $9 a ton on coal from Alberta to Ontario.

It will now be possible for the **Monongahela Ry. to proceed with construction work on its large yard at Maidsville,** in Monongalia County, W. Va., at the junction point of the Morgantown & Wheeling Ry. with the Monongahela Ry., an agreement having been reached recently. The county road will be moved to the embankment of the Monongahela River and the space between the old county road which ran alongside the railroad tracks will be utilized for thirteen yard tracks, each a mile in length, giving the railway thirteen miles of yard space between Maidsville and the Bertha mine and enabling the company to relieve congestion and handle much more coal than is now possible.

The Southwestern Interstate Coal Operators' Association and the Oklahoma Coal Operators' Association are actively supporting **proposed changes in the rates on slack coal from points in Arkansas and Oklahoma on the Frisco to destinations on the same line in Texas.** These destinations include Dallas and Fort Worth. The proposed rates are opposed by the Colorado & New Mexico Coal Operators' Association on the ground that they will create an unlawful discrimination and disadvantage against the producers of coal in the Trinidad and Walsenburg districts of Colorado and the Raton and Dawson districts of New Mexico. A large amount of testimony was given with respect to screening practice in the Colorado and New Mexico fields, and in the Henryetta group. The Southwestern operators, however, contend that this testimony is pertinent only for the purpose of indicating that "nut coal" means one thing in the Colorado and New Mexico territory and an entirely different kind, size and grade of coal in Oklahoma, and that the 3-in. nut coal produced in Colorado and New Mexico and what is denominated nut coal in group 15 in Oklahoma are not used for the same purposes and are not competitors in the destination territory involved. The Southwestern Interstate Coal Operators' Association and the Oklahoma Coal Operators' Association urge that the protest of the Colorado & New Mexico Coal Operators' Association be overruled and the proposed rates be permitted to become effective.

Rates on slack and run of mine coal from mines in the Bon Air (Tenn.) group to Richard City, Tenn., are unreasonable, in the opinion of J. P. McGrath, an examiner for the Interstate Commerce Commission. In a report made to the commission, he also holds that **rates on slack and run of mine from Orme, Whiteside, Etna and Slope Wall, Tenn., and Montague, Ala., and from mines in the Tracy City group to Richard City, are not unreasonable.**

The Utah Terminal Railroad has been given a writ of convenience and necessity to operate a railroad in Carbon County and the **Utah Railway Company** is given the status of an interstate carrier, in a decision just rendered by the I. C. C. **The Utah Railway now plans to purchase the Utah Terminal's property** which will give it all connection from the coal mines in Spring Canyon to Provo where, as an interstate carrier, it may receive and exchange cars with other lines. The decision reverses a previous one rendered in the fall of last year. At that time the D. and R. G. Western Railroad opposed the application on the ground that it was itself adequately equipped to furnish cars for the normal requirements of shippers. In addition to the petition of the railroads referred to the present application for the certificate was supported by The Spring Canyon, Peerless and Standard Coal companies. The D. and R. G. company pleaded this time that the railroad shopmen's strike several months ago had handicapped it. The Utah Terminal Railroad is a Spring Canyon line 32 miles long connecting with the Utah Railway at Mohrland. The Utah extends from Mohrland to Provo.

An injunction restraining the State Railroad Commission from putting into effect a lower rate on coal between Morganfield and Hopkinsville, Ky., was granted to the Illinois Central R.R. April 21. The order passed by the Railroad Commission, March 14, according to the petition, changed the rate on coal from $1.38 a ton to $1.07 and ordered a refund of money paid the railroad company on 2,666,660 tons of coal delivered in 1921. The order stated that the rate was "extortionate, unjust and unreasonable."

Coming Meetings

The American Wholesale Coal Association will hold its annual convention June 12 and 13 at the Gibson Hotel, Cincinnati, Ohio. Secretary, G. H. Merryweather, Union Fuel Bldg., Chicago, Ill.

Illinois and Wisconsin Retail Coal Dealers' Association will hold its annual meeting June 12-14 at Delavan, Wisconsin. Secretary, I. L. Runyan, Great Northern Building, Chicago, Ill.

Southwestern Interstate Coal Operators' Association will hold its annual meeting June 12 at Kansas City, Mo. General Commissioner, W. L. A. Johnson, Kansas City, Mo.

Pennsylvania Retail Coal Merchants' Association will hold its annual meeting May 23 and 24 at Wilmington, Del. Secretary, W. M. Bertolet, Reading, Pa.

American Association of Mechanical Engineers will hold its spring meeting at Montreal, Quebec, Canada, May 28-31. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

National Association of Purchasing Agents will hold its eighth annual convention and Informashow at Cleveland, Ohio, May 15-18. Convention headquarters, room 219, Hotel Winton, Cleveland.

The National Association of Manufacturers will hold its 27th annual convention at the Waldorf-Astoria, New York City, May 14-16.

New England Coal Dealers' Association will hold its annual meeting at Providence, R. I., June 13-15. Secretary, C. R. Elder, Boston, Mass.

National Retail Coal Merchants' Association will hold its sixth annual convention June 25, 26 and 27 at Scranton, Pa., with headquarters at the Hotel Casey.

National Safety Council will hold its twelfth annual safety convention at the Buffalo Statler Hotel, Buffalo, N. Y., Oct. 1-5. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

International First-Aid and Mine-Rescue meet will be held Aug. 27-29, at Salt Lake City, Utah.

American Institute of Electrical Engineers will hold its annual convention June 25-29, at Swampscott, Mass. Secretary F. L. Hutchinson, 29 West 39th St., New York City.

International Railway Fuel Association will hold its spring convention at the Hotel Winton, Cleveland, Ohio, May 21-24, Secretary-treasurer, J. G. Crawford, Chicago.

American Society for Testing Materials will hold its annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, N. J., beginning June 25 and continuing throughout the week. Secretary, E. Marburg, Philadelphia, Pa.

The Colorado & New Mexico Coal Operators' Association will hold its annual meeting June 20 at Denver, Col. Secretary, F. O. Sandstrom, Denver, Col.

The Electric Power Club's annual meeting will be held at the Homestead, Hot Springs, Va., June 11-14. Executive secretary, S. N. Clarkson, Cleveland, Ohio.

National Coal Association will hold its sixth annual convention June 19-22 at Atlantic City, N. J. Assistant secretary, C. C. Crowe, Washington, D. C.

Michigan-Ohio-Indiana Coal Association will hold its annual convention at the Hotel Sinton, Cincinnati, Ohio, May 22-24. Secretary, B. F. Nigh, Brunson Bldg., Columbus, Ohio.

West Virginia Coal Mining Institute has tentatively set June 5 and 6 for its annual meeting, to be held at Clarksburg, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

Retail Coal Dealers' Association of Texas will hold its eighteenth annual convention at Galveston, June 11 and 12. Secretary, C. R. Goldmann, Dallas.

The American Institute of Mining and Metallurgical Engineers has accepted the invitation extended by the Ministers of Mines of Ontario and Quebec and by the Canadian Institute of Mining and Metallurgy to hold its autumn meeting in Canada. The meeting will start Aug. 20 at Toronto and end Aug. 30 at Montreal. Secretary, F. F. Sharpless, 29 West 39th Street, New York City.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 23 NEW YORK, MAY 17, 1923 Number 20

An Opportunity

TIME-HONORED are the complaints of the employer that he has a man of the necessary power to lead and get things done and with ability to think, but that the state perniciously refuses this man a certificate though he knows more than all the "muddled oofs" who have passed the examinations and have certificates of competency.

These complaints have been joined to others. The average employer has men who would make good repairmen—steady, reliable, clever—but not grounded in their art. It is wonderful what they can do, but they lack training.

During these summer months is the time to arrange to get these men the training they need. Provision can be made at some one of the many mining schools in the country, most of which have a short summer course for students who want to be grounded in mining but have not had much scholarship as a basis for collegiate training. The right way to get the minor executive or mechanic sought is to hunt up a man who has all the requisite qualities except technical education and give him such training, be it more or less, as the office he has to fill requires more or less scientific accomplishments.

Easier Not to Mix Than to Unmix

NATURE has segregated more or less satisfactorily coal, bone, clay and slate. Once mixed they are hard to unscramble. Preparation at the tipple or washer is well, but far better is it to take care not to let the impurities get mixed with the coal. Large pieces of slate, it is true, can be removed by picking, but smaller pieces must be separated by washing or on an air table. Even then soft clay from the floor, gathered up by the shovel, can be removed only with difficulty. It cannot be picked, and though washing will remove much of it, a large quantity of fine coal will go with it.

Consequently it would be well not to disturb the clay in undermining or loading the coal. A machine that digs too low will pick up much clay and thus befoul the undercuttings and hence the whole product. Shoveling on steel plates will keep the clay from mixing with the coal, and leaving a little coal in the floor will do the same but will make shoveling less easy.

Drawslate is likely to fall, and sometimes only by prompt propping can it be kept out of the run-of-mine. Sometimes a thin film of coal left in the roof will serve the same purpose. The cuttings, if made in a parting will remove much of the impurity, especially if proper disposition is made of them. If made in clean coal, the product thus obtained may be loaded separately and will give a fuel of extra quality for metallurgical purposes and one that will not need washing. Proper shooting methods also will give a large product well fitted for the picking table.

It would pay any operator to make a careful study of his working faces to see where the impurities are and what means can be taken to provide that they are kept out of the coal, and if removed with it are kept of such size that it is easy in the tipple to separate the clean coal from refuse. An inspector or two in the mine may save a picker or two outside, may make it unnecessary to pay the miner for refuse as if it were clean coal, may enable the operator to obtain a larger and cleaner product and may help in the administration of the mine both as to safety and efficiency.

Electricity and Increased Production

ELECTRICITY is rapidly replacing man, animal and even direct-connected steam power in the coal mines. It is estimated that at the present day there is a total of about 4,370,000 hp. in electrically-operated motors in the coal fields and that this total represents about 48 per cent of the rated horsepower of all types of drivers used.

A remarkable feature of this rapid progress is that it has all been accomplished within the last thirty years. During this period there also has been an increase in coal production of almost 500 per cent and no one will doubt that the application of electricity has been the prime factor in bringing about this high rate of increase in production.

With the advantages of electrical energy so apparent it is not difficult to understand why the industry is turning to its more general use, thus opening up a greater market for all types of electrical equipment and electrically-operated machinery.

The facility and ecenomy with which electrical energy may be transmitted to places which could scarcely be reached by any other method is its paramount advantage. In using hydraulic, steam or pneumatic transmission of energy the losses are unusually high due to unavoidable pipe losses and leakages, while with electrical transmission the losses, even at great distances, are only a few per cent.

A comparatively long transmission system for electricity presents no particular difficulties, and for this reason the location of the generating station may be determined not so much with reference to the point at which the energy is to be used as to where it can be most economically generated. This makes it possible to develop water works for generating electric current, to utilize blast-furnace gases, refuse from coke ovens or low-quality fuels from coal mines. One of these sources of power that formerly was considered a waste product is available in nearly all mining districts; especially is this true in the anthracite field, where it is possible to use old culmbank fuel mixed with the smaller sizes, as the case may require.

In addition to the advantage of utilizing so-called waste products for power purposes, the electric central

station and the attendent centralization of the loads makes the engine load more constant and provides a means of securing the most favorable steam and fuel consumption. This matter of load factor is so important that a recent survey of seven large coal mines, each furnishing its own power—mostly for steam-driven equipment—revealed a total boiler capacity in continuous operation equivalent to twice that necessary to operate a central station of sufficient size to operate the total connected power load electrically.

Such central-station systems are gaining in favor in the coal fields, both in the way of large central power plants for individual coal companies and public-utility companies. At present it is estimated that the total amount of electrical energy used in the coal fields is about equally divided between power plants owned by coal companies and public-utility companies.

Putting It Up to the Fan

WHEN a mining engineer wants to double the length of his trips, all he has to do is to double the weight of his locomotive and double the power of its motors. If his rails and the couplings will stand the load he can readily get the locomotive or use two in tandem. Increasing the tonnage of his trips does not increase his power cost per ton and, as it saves labor, may actually reduce his whole cost for haulage. Besides, if he hauls in one trip what he formerly has hauled in two he removes the possibility of the trips interfering with one another.

He may have to increase the capacity of his feeders and may have to enlarge his central station, if he has one, and increase the size or number of his substations. He may have to pay more for power if he uses so much in hauling his long trip as to heighten the peak load. Barring that last possibility the factor of increase of every item is two or less than two because it may be possible by having longer trips to get some help in overcoming unfavorable grades, for some cars may be on a more satisfactory grade than others, thus helping the locomotive to perform its work. A long trip often is a gradient equalizer.

Operators frequently forget that it is different with a fan. With a given length and size of airway, doubling the volume of the air current means not doubling but multiplying by eight the power of the fan needed, an increase not to be dismissed without careful consideration. It means increasing the leakage of brattices and stoppings, which may make the factor of eight insufficient. It should be remembered that the mine will take only the number of cubic feet that the pressure of the fan acting on the resistance of the roadways will permit to pass through the working. To increase the flow of air the pressure of the fan must be increased.

Consequently the operator, seeing the roadways get longer and longer and in some cases lower and lower as the bottom rises toward the roof due to squeeze and also the airways become more and more cluttered with fallen rock, if it is not removed, will do well to plan carefully when he opens his mine.

He will do well to watch his intake carefully. If it must be a single airway and if he cannot add another later he should make it large, remembering that it has to take an unsplit current. If it is a shaft he should design it not merely to suit the needs of hoisting but with a view to the future requirements for ventilation. He will be well advised if he splits his current as early as possible and avoids curves and offsets as much as he can in such airways as carry the unsplit current. He will watch closely the return, especially where all the various splits have rejoined and are coursing along in one narrow pathway together. The reunited return should be short as is the unsplit intake.

Whatever he does let him not "put it up to the fan maker." He may buy a fan that will deliver enough air and create enough pressure to satisfy his notion, but if his mine will not carry that much air with that pressure the fan will not deliver it. His only hope may be to make a new shaft for the intake or the return or both, or to drive new roadways if the pillars will permit it. Let him remember that the laws of nature are unalterable, and with a badly planned mine a fan will not deliver the required quantity of air except with excessive water gage, and a misuse of power well nigh appalling. He will do well to listen to advice in this respect lest in arguing he find he is trying to combat laws of physics with which none can parley.

Pumping Replaces Ditch Drainage

GRADUALLY the bituminous-coal mines above water level are being worked out. They, like the anthracite mines, are getting deeper year by year. It is true that at most soft-coal mines only one seam is being worked, but such seams are being completely extracted, which is not always the case in the anthracite region.

If we could believe Fayol and the old school of mining men we could feel confidence that the deeper mines would be fed only with "ground water," which when exhausted would be replenished only slowly, but experience shows that the old school is wrong, that the whole area above an extracted coal bed does subside and in subsiding stresses, strains and breaks the rock cover, leaving crevices down which water can percolate more or less freely.

The extraction of one bed, as is the rule in the bituminous-coal region, is not so disturbing as the removal of several, as in the anthracite coal field, but when only one bed is worked the area undermined is greater for any given tonnage, and the water to be handled per ton of coal mined may be little if any less. When the mine is below water level all this water must be pumped. The weakest spots are where the cover is least—that is where the streams are biggest.

For this reason we can look for big influxes of water and an increase in the volume to be pumped. Consequently the pumping load in the soft-coal mine will increase and ultimately it may be no less than in the anthracite region.

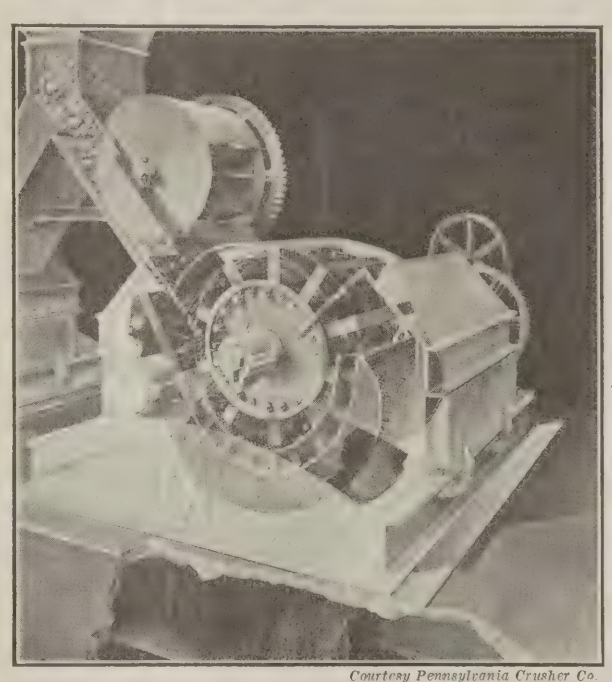
Subsidence, therefore, becomes an important problem. How close can an excavation be made to a stream? We are clear that it is not well to mine under it, but it is questionable how near it is well to approach it. In fact the point of approach that will give security against flooding by streams will indicate how far cracking of the surface extends beyond the excavated area.

This is one of the reasons that makes the inquiries of the committee on ground movement of the American Institute of Mining and Metallurgical Engineers so vitally important. To keep down pumping expenses the coal under and near streams should be left intact till the final pillar drawing is commenced, provided the stream is large and the water it carries accordingly is menacing.

Equipment Layout for Washery to Clean Coal as Prelude to Making Metallurgical Coke*

Finding Out What Size Coal Most Needs Cleaning—Three-Quarter Inch Crushing Usually Fine Enough—Equipment Needing Little Screening a Desideratum—How to Avoid Dewatering of Coal—Some Formulas

AS IS IMPLIED in its title, this article will deal strictly with coal that is to be washed for use in the manufacture of metallurgical coke. It now is being generally recognized that the areas in which coal having sufficiently low percentages of ash and sulphur for the manufacture of good metallurgical coke is found are being depleted rapidly, and that, in consequence, coal washing before long will have to receive the attention it deserves from mining, metallurgical and chemical engineers.



Up to the present time coal washing has been looked upon somewhat as a necessary evil to be avoided like a pestilence, and when coal has been washed at all it has been done only in a half-hearted or desultory manner. Lately, however, the problem has been receiving much attention at meetings of coal-mining men, where it often forms the topic of lively discussions of absorbing interest. Moreover, from time to time, new and improved schemes are being developed that put coal washing on a higher plane than heretofore. It will be the purpose of this article to formulate a general plan, or layout, of coal-cleaning equipment that will enable the prospective owner of a mining plant to install equipment that will clean his particular coal in the most efficient and economical manner.

To illustrate the point a flow sheet (Fig. 1) has been prepared which is intended to cover the subject but in a way permitting of modifications. The different steps and combinations will be discussed in the order of their importance.

Preliminary Investigation.—The importance of a preliminary investigation of the coal to be washed cannot be too strongly emphasized. This has been indicated forcibly by Messrs. Fraser and Yancey, co-investigators at the Engineering Experiment Station of the University of Illinois. It will pay every coal operator who contemplates the installation of coal-washing equipment to read their published opinions on this subject, for they are sound in logic and afford good advice. After all experimental data have been collected, the interpretation of the results is important and should be done only by a competent and level-headed engineer—one who is unprejudiced when it comes to the installation of the proper kind of coal-cleaning equipment.

It probably is a statement of fact to say that the burden of the investigative work is carried out by crushing and screening tests, coupled with the so-called sink-and-float examination and by chemical analysis of the various products. Table I shows the results of such an examination on a certain coal the treatment of which is in need of determination.

On examining the results in the above tabulation it will be noted that the character of the coal is much the same in all the sizes, which makes the cleaning of it difficult. It will be further noted that the sink-and-float tests indicate that the percentage of sulphur in the float coal is nowhere low. This float should correspond with the washed coal.

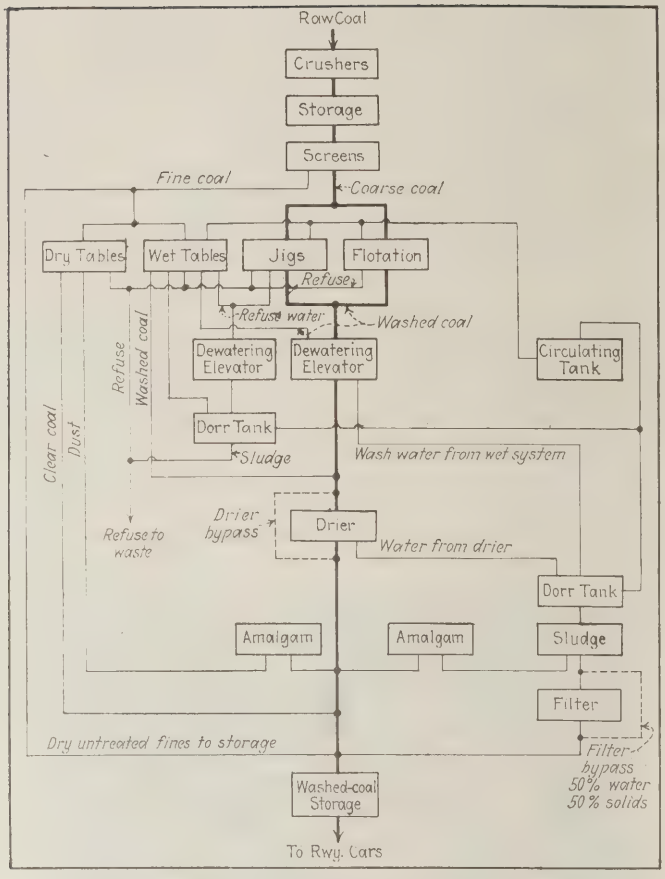
PHANTOM DRAWING ON HAMMER CRUSHER AT WORK



In the upper left-hand corner is the chute, the discharge from which is regulated by a retarding and distributing feeder, the coal passing into the hammers at about the level of the diameter of the axle. The hammer lifts the coal and drives it against the casing. Whatever is friable enough to be thus broken, including all the clean coal, is passed through the screen openings on the underside of the crusher. Whatever is not, whether slate, bone coal or tramp iron, is ejected beyond the screen.

This experimental indication has been borne out in the washing of this coal, but, as the writer has pointed out in a previous article on the subject, the actual sul-

SUGGESTED FLOW SHEET FOR WASHERY

This illustration is a broad generalization which may be modified to meet the special needs of any given installation. The coal is crushed to ¾ in. diameter. The storage is placed between crushers and screens although it may be conveniently located elsewhere.

phur in the washed coal from a well-designed and properly operated washery will be lower than the sink-and-float tests would indicate. As a matter of fact, also, the percentage of loss in weight in washing is lower, the ash percentage is higher, and the percentage of sulphur lower, than the tests would indicate. To illustrate further the necessity for preliminary investigation, another example is cited in Table II.

TABLE II—TESTS AND ANALYSES OF COAL HAVING MOST OF ITS IMPURITY IN THE COARSE COAL

Constituents	Raw Coal Per Cent
Volatile matter	18.60
Fixed carbon	72.45
Ash	8.95
Total	100.00
Sulphur	0.84

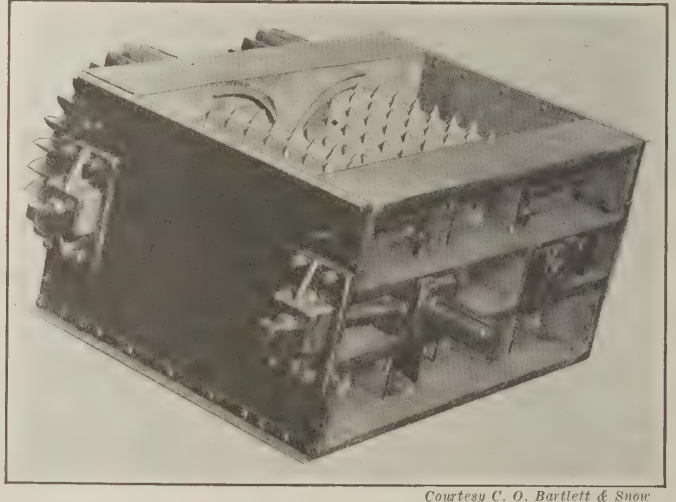
On referring to the analyses of the screening tests in Table II, it will be noted that the impurities for the most part are found in the larger sizes. In this case it would be unwise and uneconomical for the coal operator to figure on cleaning any size below 8-mesh. This side quite properly may be allowed to bypass the coal-cleaning equipment, and be added untreated to the clean coal. This is readily accomplished by means of screens.

This feature is important in the cleaning of certain kinds of coal, and advantage should be taken of it whenever possible, for it means a big saving in equipment and cost of operation. Care is taken of it in one of the layouts shown on the flow sheet. The same characteristic is not shown in the first example cited, Table I, in which the fines could not be added untreated to the clean coal without a considerable increase in the ash and sulphur contents of the final product.



Crushers.—As to crushers the types to be installed will depend largely upon the character of the raw coal and its impurities. Generally speaking, it is found in practice that when the coal is crushed to ¾ in. it will be fine enough to free the impurities for commercial operation. In certain layouts fine crushing is objectionable, as it results in the production of a large percentage of excessively fine coal. In fact it may be said that when the crushing equipment is chosen this possibility should be kept in view. In wet washing it is difficult to handle fines successfully.

Among the types of primary crushers may be mentioned the toothed-roll crushers, the Hammermill and the Ring crushers. Sometimes, as in the making of amalgam, to be described later, ball or rod mills may be used. These are designed to powder coal to 100-mesh and under. If the amalgam method ever has any wide application, these mills, of course, will be more than auxiliary crushers.

Storage.—What storage is provided will be determined largely by the operating conditions. In the flow sheet it is shown as being placed between the crushers and the screens, although it may be located conveniently elsewhere. Under certain conditions it may be even omitted.

Screens.—In a well-regulated coal washery producing coal for the manufacture of metallurgical coke, a screening plant would seem to be absolutely necessary, as higher efficiencies are obtainable when more or less sizing is done. The coal should be screened thoroughly or not at all; otherwise the efficiency of the washery will be much impaired. Where a jig designed for handling coarse coal is used for cleaning a mixture of fine and coarse coal an excessive quantity of good coal, chiefly fines, is almost certain to be lost in the refuse.

The flow sheet shows two general heads—fine coal and coarse coal. By fine coal is meant coal under ¼ or ⅛ in.

TWO-ROLL TOOTHED CRUSHERS FOR BREAKING COAL

These crushers are designed to break rather than crush the coal. The action is more like that of a series of picks than that of a steam roller, which latter starts cracks everywhere and makes a powder rather than a granular material. The segments of the rolls can be made of cast-steel, chilled cast-iron, or manganese steel. The crusher measures 26x24 in.

Concentrating Table

The fine coal with the aid of water and the reciprocating motion of the table passes over the riffles and is taken off at the side of the table. The sluggish slate is not so agile in hurdling the riffles, and lands at the end of the table.

Courtesy Deister Concentrator Co.

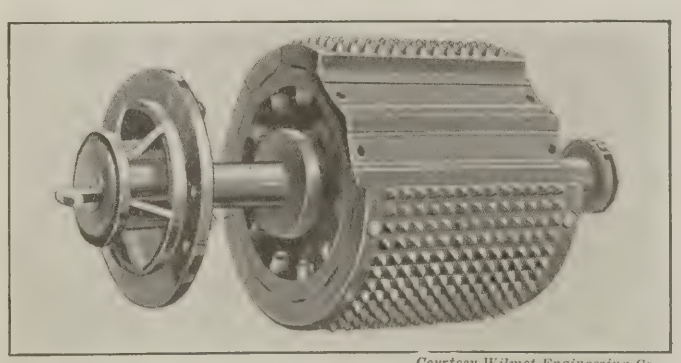
or thereabouts. Coarse coal is above that and may be conveniently divided into two sizes before going to the jigs or other cleaning equipment.

As to the screens themselves great care should be exercised to select that type which will give the greatest efficiency for a given area of floor space. Apparently the tendency of late has been toward the use of vibrating screens of some sort, although there are efficient screens of the shaker-gravity and anti-gravity types.

Method of Cleaning Coarse Coal.—The flow sheet shows two general methods of handling coarse coal—jigs and flotation. There probably is no better or faster method of cleaning coal than by the use of jigs. No attempt will be made to discuss the merits of the different types of jigs on the market. When tuned up properly, any of them will do fairly efficient work on coarse coal, if the coal is accurately sized. It always seemed to the writer that a single-cell jig was the most logical one to use when at all possible, and in no instance should a jig having more than two compartments be used.

Flotation is shown in the flow sheet as a method of handling coarse coal, as lately at least two methods have been developed for this purpose, and both are being used by a well-known company in the anthracite district. In fact no less than seven flotation plants of one of the two types mentioned have been installed. Sand pulp or a similar material is used for the flotation medium. If flotation can be developed for use on bituminous coals, it appears, at least at first sight, that it would have a rather wide application even to the point of supplanting the use of jigs under certain conditions, on account of the process being faster and more economical. In the light of present knowledge the process seems to imply efficient screening, or the removal of the extremely fine coal and the prevention of abrasion afterwards, because when fines have become mixed with sand pulp they are separated with more or less difficulty.

Method of Handling Fine Coal.—Fine coal, say below $\frac{1}{8}$ or $\frac{1}{4}$ in., may be handled in many ways: (1) Direct or untreated to the washed coal proper; (2) on dry tables; (3) on wet tables. The handling of untreated coal has been described somewhat in detail already.

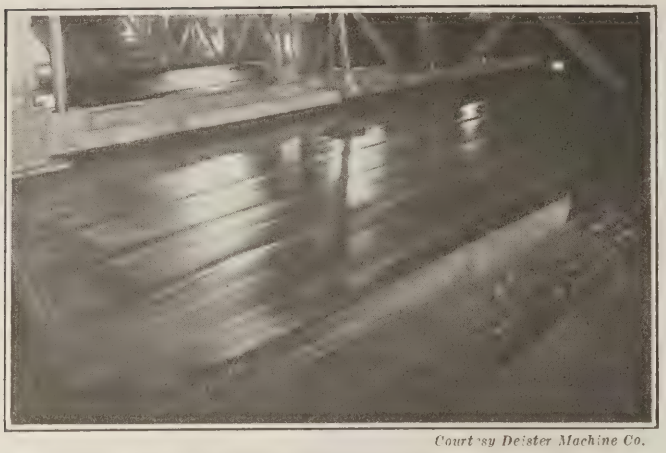


Dry Tables.—Of late coal operators have been giving dry cleaning more than passing attention, as it has many advantages over wet methods, chief of which, when the coal is used in the manufacture of metallurgical coke, is the elimination of water in the washed product. This process not only saves freight on water but helps out at the byproduct oven by a reduction in the coking time. It also has other desirable features. Several dry tables are on the market. Some already have been developed commercially and some are merely in process of development.

One type of dry table requires close sizing. The sponsors for another type assert that it will handle unsized coal below $\frac{1}{4}$ or $\frac{1}{8}$ in. It may be remarked here that in most cases grading in eight or ten sizes is objectionable. It would seem more logical to treat the fine coal unsized, as is the practice on wet concentrating tables. Dry cleaning undoubtedly will play an important part in the coal-cleaning equipment of the future, and it will be to the manufacturer's advantage to develop dry tables that will be as simple as possible and that can be operated with maximum economy.

Wet Tables.—Little need be said about tables of this type, as they are already in successful operation. Like jigs, any of them will do good work when properly adjusted. The choice made will depend largely upon their cost, tonnage and ability to withstand heavy usage.

Dewatering Elevators.—Close attention should be paid to the design of dewatering elevators both for the washed coal and for the refuse, particularly the former. If the perforated buckets are well designed and proper pitch and speed are maintained, they will remove a large quantity of water. In fact if only coarse coal is being handled on the dewatering elevators and if the dry fine coal is added afterward, it is unnecessary to provide any other way of eliminating water. In other words, the centrifugal driers may be bypassed.



Mechanical Driers.—The tendency in coal-washing equipment is to use mechanical driers, or centrifuges, inasmuch as they are comparatively inexpensive to operate, do their work efficiently and occupy little floor space

TWO COAL-WASHING TABLES AND THEIR FEED

The quiet flow of water contrasts greatly with the disturbance in the older types of jig. It is better suited to the fineness of the material with which it has to deal. The table is being agitated along the lines of the ripples. The table feed should be less than $\frac{3}{4}$ in. in diameter. Water is added to equal 50 per cent of the weight of the solids, and from 15 to 20 gallons of dressing water per minute are admitted in two boxes or hoods, one immediately in front of the feed box and one about halfway down the side of the table.

as compared with drainage bins. The cost of operation is less than 2c. a ton. There are two well-known types of mechanical driers on the market. Here again the problem is determined largely by the first cost and floor space.

Sludge Recovery.—No matter how careful has been the attention given to the washery layout, particularly the crushing equipment, a certain quantity of fines always will be produced. In this sense the fines are the powdered coal produced by grinding and abrasion; they usually are about 100-mesh material. The percentage varies, depending upon the character of the coal, but usually it is not less than 5 per cent of the input of the washery. In the old days a large part of this fine coal was lost, due to imperfect sludge tanks.

There is no longer much excuse for permitting that loss, if the coal operator is willing to spend the money for an approved method of handling wash water and the sludge from it. As no other type of apparatus is on the market, reference is made in the flow sheet to the Dorr thickener, which serves as a mechanical means of handling the wash water and sludge.

The effluent from these tanks may be so regulated as to contain only a few tenths of one per cent of solids, the quantity averaging probably one quarter of one per cent, consequently it is amply pure for re-use in the washery. The underflow can be thickened down to approximately 50 per cent of solids and 50 per cent of water. Practically the same remarks apply to the use of Dorr tanks for handling refuse water, although here the underflow has to be wasted because of its chemical analysis.

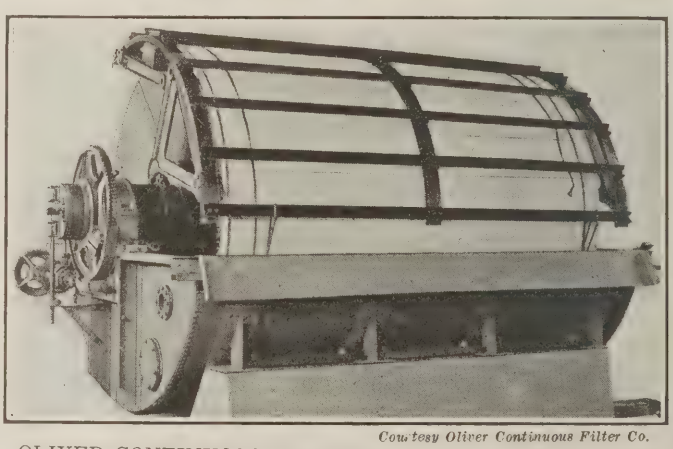
Handling Sludge.—The sludge can be disposed of in several ways: First, where there is no objection to water, it may be pumped directly on top of the washed and dried coarse coal proper, which eliminates it from the circulating system altogether. Second, the underflow may be put through a filter of some kind to reduce the moisture in it before it is added to the washed coal. The use of a drum, or disk, filter probably will reduce the moisture 50 per cent. The cake thus obtained is easily handled. Third, it has been proposed to make an amalgam of the sludge with oil, a process by which, it is asserted, not only the moisture but also the impurities of ash and sulphur are reduced.

According to the claims made for the process, the moisture of the amalgam runs from 10 to 15 per cent, the ash is reduced at least 50 per cent, and the sulphur is lowered to a point near the organic sulphur content of the coal. Furthermore, in the byproduct process the oil is said to be recovered in the form of additional heat value in the gas and in an increase in the tar and motor fuel thus obtained. Although this process is not completely developed, yet in so far as it applies to handling sludge it deserves careful attention and investigation on the part of coal operators.

The same remarks apply in general to making amalgam from the dust of the dry tables, as it has practically the same characteristics as the sludge from the wet washery. In the case of dust, water would have to be added in making the amalgam. In passing it may be remarked that the dust may be recovered from dry tables by means of an exhaust, or blower, system, which seems just as necessary as the Dorr tank in wet concentration.

Mathematical Formulas.—It already has been pointed out that there are formulas based on chemical analyses by which the various problems that arise in coal-washery management can be solved. For instance, in the analysis of the raw coal, washed coal and refuse, the percentage of loss may be calculated even more accurately than by using actual weights. Some of these formulas are as follows:

If H equals the raw coal; W, the washed coal; and R the refuse,

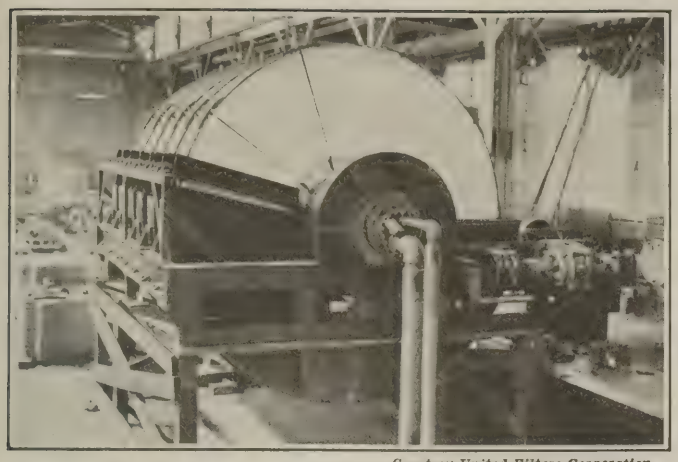


$$\text{Then } \frac{R\text{-}W}{H\text{-}W} = \text{Ratio of Elimination.}$$

Dividing 100 by this figure gives the percentage of refuse, and of course 100 per cent minus the percentage of refuse = the percentage of washed coal.

In a similar manner

$$\frac{}{(R\text{-}W)H} = \text{Percentage of Elimination of Ash or Sulphur.}$$



The work of the Dorr tanks may be investigated from the following formulas: If A equals the specific gravity of water; B, that of coal (say 1.35) and X that of the solution under consideration

Courtesy Oliver Continuous Filter Co.

OLIVER CONTINUOUS FILTER FOR DRYING FINE COAL

The filter removes water by sucking the wet coal onto its outer permeable surface and subjecting the layer thus formed to the action of a vacuum within the filter. It consists of a drum or cylinder rotating on a horizontal axis with the lower portion submerged in a tank containing the material to be filtered. The surface of the drum is divided into compartments or sections, the dividing partitions being parallel to the main shaft. These sections are covered with a screen for supporting the filter medium, which is held in place by a wire winding. Each of these sections is connected by means of pipes passing through a hollow trunnion to an automatic valve, which controls not only the application of the vacuum for forming and drying the cake but the admission of air which permits the cake to be scraped loose.

Courtesy United Filters Corporation

AMERICAN CONTINUOUS FILTER WITH DISK SECTIONS

Each section consists of eight to ten separate sectors, each consisting of wood corrugated like a washboard and covered with filter cloth. The shaft is hollow and the moisture in the coal is drawn by the action of this vacuum through the cloth into the corrugations and down these through an orifice in the shaft to the shaft center. By the use of disks a larger area is exposed to the action of the vacuum. The cloth bag on each sector is separate and can be renewed without renewing the covering of other sectors.

Then $\frac{B(X\text{-}A)}{X(B\text{-}A)} \times 100 =$ Percentage of solids in solution.

This formula is particularly valuable in investigating the character of the underflow and, if necessary, the water consumption of the plant, based on the quantity of underflow during any given time.

As to formulas for calculating the efficiency of a coal washery not much can be added to what Messrs. Fraser and Yancey have said in their bulletin on "Interpretation of Coal-Washery Results." These equations are known as the Drakeley formulas, and are given below:

$$\text{Qualitative Efficiency} = \frac{\text{Washed coal float—Raw coal float}}{\text{100—Raw coal float}}$$

$$\text{Quantitative Efficiency} = \frac{\text{Raw coal float—(Refuse float} \times \text{percentage of refuse}}{\text{Raw coal float}}$$

The general efficiency of the washery is considered to be the product of the qualitative and quantitative efficiencies. Objection might be taken to the Drakeley method of obtaining the general efficiency of a washery. For instance, if the washery operator wishes to show a high general efficiency, all that is necessary is to produce a washed coal with only a small percentage of sink in it, which gives him a high qualitative efficiency. But this procedure in all probability would cause an unduly high percentage of good coal to enter the refuse.

G. R. Delamater some years ago published formulas for determining the efficiency of coal washeries which have been subjected to more or less criticism, but after all it seems, according to Messrs. Fraser and Yancey, who have made an exhaustive study into the question, that he was fundamentally right. These authorities have combined the ideas expressed by Drakeley and Delamater into new formulas for showing the general efficiency of a coal washery. These are as follows:

$$\frac{\text{Actual Yield}}{\text{Standard Yield}} \times \frac{\text{Actual ash reduction}}{\text{Standard ash reduction}} \text{ or}$$

$$\frac{\text{Yield of washed coal}}{\text{Yield of float coal}} \times \frac{\text{Raw coal ash—Washed coal ash}}{\text{Raw coal ash—Float coal ash}}$$

Delamater was undoubtedly a pioneer in the literature of coal washeries and in the development of formulas, and as such deserves full credit for his work, even though he made mistakes, as all men will who do original thinking or investigative work.

Applying the principles of Drakeley's formulas, a modern up-to-date coal washery should show a qualitative efficiency of 75 per cent and a quantitative efficiency of 97 or 98 per cent, which will give a general efficiency of 73 or 74 per cent, although Prochaska in his book on "Coal Washing" says 65 per cent may be considered average coal washing practice. He also says that 75 per cent general efficiency is excellent work, but it would appear to the writer that this figure is about what ought to be expected of modern equipment.

Aside from the coal-washing equipment shown in the flow sheet, it may be remarked that there are cases where coal may be cleaned sufficiently by picking tables, picking screens and certain types of revolving screens and disintegrators. These various machines have merit and should be used whenever it is found that they will do the work efficiently.

Ontario and Quebec to Entertain American Institute of Mining Engineers

BEGINNING at Toronto, Aug. 20, and ending at Montreal, Aug. 30, the American Institute of Mining and Metallurgical Engineers will visit several of the mining regions of Ontario while holding its annual fall meeting.

The tentative itinerary contemplates meeting in Toronto and registering on Monday morning, Aug. 20. After a luncheon, entertainment will be offered by Toronto members of the Canadian and American institutes. The party will leave Toronto in the evening on a special train, arriving at Sudbury on the following morning, and will devote the day to visiting the mines of the district, including the Creighton, and the smelting works of the Mond Nickel Co. at Coniston.

Wednesday, Aug. 22, will be devoted to inspecting the mines and mills at Cobalt, and on Aug. 23 the company will be divided into two sections, one going to South Lorrain by automobiles, the other making a boat trip on Lake Timiskaming, visiting the Wright silver mine (Canada's oldest mine) and Ville Marie, one of the oldest Canadian settlements in Ontario.

On Friday the party will be at Kirkland Lake and spend the day in visiting the mines and mills of that district.

On Saturday morning the first stop will be made at Iroquois Falls, where is located the Abitibi Pulp & Power Co.'s plant, one of the largest paper mills in Canada. In the afternoon the party will proceed to Porcupine, where it will be entertained that afternoon and the following day.

On Sunday evening the special train will start toward Quebec over the Canadian National Lines, reaching that city Monday afternoon. While in Quebec the party will be quartered at Château Frontenac.

Tuesday, Aug. 28, will be devoted to technical sessions, the program of which will be announced later. On Wednesday the party will be driven in automobiles to points of interest in and near Quebec, and in the evening a formal dinner will be served, at which short addresses will be given by members of both the Canadian and American institutes. After the dinner the party will return to its sleepers and will reach the Thetford asbestos mines early Thursday morning. The morning will be spent here and at Black Lake, the party taking the train again at noon for Montreal, where a smoker will be held, concluding the program of the meeting.

Bunker and Cargo Coal Destroy Many Ships; Suggestions to Reduce Hazard

THE seriousness of fires on ships due to spontaneous combustion in bunker and cargo coal has led the Department of the Interior to undertake a study of causes and means of prevention, the results of which are given in Technical Paper 326, written by H. H. Stoek and just issued by the U. S. Bureau of Mines, from which source it can be obtained.

A tabulation of casualties from fires on British ships shows that the number of fires caused annually by spontaneous combustion ranges between 50 and 100. The average number of American steamers totally destroyed by fire each year is over 60. In addition, about 140 vessels of miscellaneous types are destroyed, a total of 200 per year. Property losses by fires on ships run into the millions of dollars. The loss of life has been considerable. What portion of these totals should be attributed to coal fires has not been ascertained.

Loss Is Not Limited To Actual Fires

The money losses listed do not include those due to delays in sailing incident to the heating of coal cargoes or to the cost of removing cargoes that have heated. In New York harbor, coal that has heated to 120 deg. frequently is refused for bunker and cargo purposes and other disposal must be made of it. Within the last few years coal handlers in several South American ports have required extra pay for handling coal that has heated.

As a result of its investigations, the Bureau of Mines considers that the danger of loss of life or of a total loss or damage to vessels from coal carried in bunkers or as cargo is sufficient to justify unusual caution in choosing, handling and watching coal placed on ships either for bunker purposes or as cargo.

Undoubtedly certain coals are more liable to spontaneous combustion than others, but the information available at this time does not permit a classification of coal to be made upon this basis. Hence when a choice is possible, a coal that, as shown by its past record, is particularly liable to spontaneous combustion should not be put on a ship. If choice is not possible, and coal with a bad record must be used, it should be carefully stowed and sedulously watched.

Liability to spontaneous combustion is greatly reduced if fine coal and dust be removed by screening, but usually this is not practicable with present coaling methods. Run-of-mine coal generally is furnished to ships, particularly at American ports, both for cargo and bunker purposes. With coal of mixed sizes such as this extra precautions must be taken. If possible, the least friable of the coals available should be chosen, and care should be used in handling the coal in order that breakage and crushing may be reduced to a minimum.

Even Low-Sulphur Coal May Give Trouble

It is wise to select a low-sulphur coal, if possible; but it must not be taken for granted that because of that quality it will be free from spontaneous combustion.

The evidence in regard to the chemical action of moisture in coal in aiding or retarding spontaneous combustion is extremely contradictory. As vessels usually must be coaled promptly, no attention can be paid to weather conditions, and it seems to make little difference as to the tendency to fire whether coal is loaded in wet or in dry weather.

Practice and opinions vary widely in regard to the ventilation of bunkers and holds. Many advocate keeping the coal spaces as nearly airtight as possible by battening down the hatches, but others advocate taking off the hatch covers, when weather conditions permit, to admit air to the surface. Adequate ventilation throughout a coal cargo by pipes or by chimneys built of coarse coal through the pile, as is advocated by some, is impracticable, and it seems better to distribute the coal uniformly and to prevent as far as possible segregation of the sizes, as such segregation tends to produce areas favorable to heating. Moist air circulating through a coal pile seems to cause it to ignite at a lower temperature than it would if the air were dry.

Bunkers and holds should be provided with ventilating funnels to carry off the explosive gases which some coals give off, and great care should be taken in opening a bunker or hold that has been tightly closed to test for explosive gases. In closed spaces where coal is stored, open lights should be prohibited.

Further recommendations of the Bureau of Mines' investigators are as follows: When coal is loaded trim it, if possible, in horizontal layers to avoid separation of the sizes, rather than dump it on a cone and thus permit large lumps to roll to the bottom of the cone and the fine coal to collect near the top of the pile, just under the hatches, where fires are often known to start.

Thoroughly clean out bunkers and holds before fresh coal is put in, and closely inspect coal as it is being loaded, removing from it any waste or pieces of wood, paper, or similar combustible material which may assist spontaneous combustion. The placing of fresh coal on old coal that has been in the bunker for some time is generally considered unwise.

Protect Coal From Boiler Heat

Keep the coal as cool as possible, and avoid placing it in contact with outside sources of heat, such as steam pipes and hot-air ducts. Protect bunkers from the heat of boilers and engines. Take the temperature of the coal at regular intervals, the oftener the better, if there is any tendency to heat. If the temperature reaches 100 deg. F. and is rising rapidly, move the coal to cool it off by contact with air, steam, or, in extreme cases, water. If water is used, burn the coal as soon as possible and keep it separate from the other coal, as the application of water to hot coal breaks it up and by thus exposing fresh surfaces renders it more liable to spontaneous combustion.

Provide an adequate steam supply, hose, pumps and other fire-fighting equipment, and always keep them ready for use. Some automatic fire-detecting apparatus in the pilot house or engine room is advisable.

Provide for the egress, before men enter places where coal is kept, of explosive and other gases that are given off by coal, and avoid open lights in cargo and bunker spaces. Clean the vents leading from bunker or cargo spaces after coal has been put in place.

Clean out thoroughly, when the ship goes out of commission, all spaces where coal has been kept, as fine coal left in corners and on ledges frequently fires. Do not run electric wiring, unless in metal conduits, through spaces in which coal is placed. Use every precaution to prevent sparking at electric contacts.

What Alternating Current Has Done to Increase The Application of Electricity to Mining

Great Flexibility of Alternating-Current Distribution System—Better Voltage and Better Operation—Simplicity of Control, Ease of Repair, Ruggedness of Construction of Alternating-Current Equipment

By Edgar J. Gealy
Electrical Engineer; Associate Editor, *Coal Age*

IN THE earliest coal mines the only form of energy used was human energy, supplied by men, women and children. Later animal, hydraulic, pneumatic and steam energy were added, while today we find included in the list that seemingly all important form of energy called electricity.

Electricity as used in the mines falls into two rather distinct divisions, namely: direct-current and alternating-current. Direct-current, being the more simple form of electricity, was early adapted to coal mining, another important reason for its early use in mining being the fact that direct-current motors better fitted requirements in the mines while alternating-current motors had not been developed to this degree. As long as direct-current was the only form of electrical energy in the mines electrical application was on a moderate scale.

More extensive development of electrical equipment has now placed the alternating-current machine in a position where its application to mining has so many advantages over the direct-current machine that it stands in a fair way to supplant the direct-current machine.

With the sole exception of the haulage locomotive there seems to be no piece of electrical mining equipment which cannot be operated as well on alternating as on direct current.

Economy of Alternating Current

Under the present stress of economic conditions it is imperative that everything be done to increase the tonnage of coal produced per man employed. This means that a greater amount of machinery must be used, and since this machinery evidently is to be driven by electrical equipment we are confronted with the problem of maintaining an ample supply of electrical energy so that each man may be able to get out a good day's work without any reasonably avoidable delay. To accomplish this it is important that the electrical energy be supplied at a voltage that will permit all the equipment to function both efficiently and economically.

With direct current it usually is necessary to limit the range of distribution to one mile for 250 volts and to four miles for 500 volts because this is the economic limit for these potentials. Beyond these distances so much copper would be required as to make the proposition impracticable. We frequently find that these limits are greatly exceeded, however, and it is here that one must realize the importance of that increasingly important subject, engineering economics.

To illustrate the conditions which arise on a long distribution line let us take a case where the voltage between trolley and rail is to be determined in a 250-volt mine using 4-0 copper trolley wire and a single 4-0 solid copper feeder in parallel, the voltage to be determined at a point 3,000 ft. from the direct-current generator and the current to be assumed at 500 amperes. Under these conditions the voltage drop would be 70, thus leaving only 180 volts between trolley and track at the point mentioned.

Standard electric motors are designed to operate satisfactorily at 10 per cent under voltage or 10 per cent over voltage. Obviously even with the large trolley and feeder in the above example the resultant voltage remaining is far too low to give satisfactory operation.

From the fundamental laws governing the drop of voltage in conductors we may draw two important conclusions: (1) With the amount of power to be transmitted and the distance fixed, if the loss is to be cut in two, the wire will have to be doubled with a given voltage; (2) if the percentage of loss is to remain constant and the voltage is doubled, the wire may be cut in four—that is, actually reduced to twenty-five per cent in size.

Advantages of High-Voltage Distribution

Obviously high voltage is one of the greatest boons to electrical transmission. With a direct-current system the only feasible means of changing the voltage either up or down is by the use of a motor-generator set that is expensive, relatively inefficient and also requires more or less attention. With an alternating-current system the voltage may very readily be either raised or lowered by means of a transformer, a piece of electrical equipment which operates at high efficiencies and with little or no attention.

From this it is evident that the direct-current system is limited to those installations where all the energy is to be used within a relatively short distance of the power plant, whereas the alternating-current system lends itself to an almost unlimited distance for distribution. As the workings of the mines are extended and it becomes increasingly more difficult to keep up the voltage at the face the alternating-current distribution system increases in importance and economy.

Frequently a new mine is opened and developments at first are carried on in a small way with direct-current used for the distribution of electrical energy. If the mine succeeds this is almost invariably found to be a mistake because as the operations become more extensive in both distance and electrical needs, greater capacity is demanded in the equipment for converting alternating current to direct current or better voltage is needed at the face, which will require increase in voltage or extensive layouts in copper feeders.

Aside from the advantage gained by the use of smaller conductors used on alternating-current systems we have the added advantage of greater flexibility with the use of alternating current.

Transformers may be installed in almost any part of

the mine and, where necessary, they may be enclosed in fireproof concrete vaults, making the possibility of damage from fire very remote. The locating of the transformers near the place where the energy is to be used makes possible the transmission of almost any conceivable amount of available capacity. With the alternating-current system it is a very simple matter to extend the system at any time, stepping up the voltage when necessary to get to any remote point.

Under the present high stage of development of the alternating-current induction motor its application to various forms of drives has been markedly successful. The three-phase motor is most generally used and depending upon the frequency and number of poles in the stator winding practically any desired speed may be obtained without any additional control equipment outside of a starter. These advantages make it possible to apply the induction motor to a large number of applications and greatly simplifies the gearing system, in fact, the gearing may be entirely eliminated in many cases.

The squirrel-cage induction motor has been extensively applied to pumps and fans with conspicuous success, maintaining almost constant speed under wide variations in load. Here the ruggedness of the motor has proved itself, it having no commutator, but instead a simple rotor winding and a simple stator winding it is little affected by the mine humidity or splashing of water from the pump or fan. Another advantage is the relative ease with which a temporary repair can be made when a coil or coils in the stator break down; in this event it is rarely necessary to do more than "cut-out" the bad coil or coils by making a reconnection on the ends of the winding, which are easily available. Frequently important motors have been successfully operated for days and weeks with as much as 15 per cent of the winding "cut-out" until repair parts were received and the repair made.

We therefore find that the use of alternating current enables the engineer to maintain better voltage for all equipment, renders the energy distribution system more flexible, effects greater simplicity, lessens the need for repairs, affords larger assortment of equipment at lower cost and better deliveries.

Engineers, Scientists and Editors Plan Uniform Symbols and Abbreviations

A RECENT meeting held in New York City under the auspices of the American Engineering Standards Committee to further discuss the desirability of and procedure to be followed in establishing a unification of technical and scientific abbreviations and symbols was attended by a large and representative group of engineers, scientists, government officials, business-paper editors and industrial executives.

It was agreed that the standardization would result in inestimable mental economies, as the present situation with respect to the use of scientific abbreviations is comparable to a language that has degenerated into a multiplicity of dialects.

Abbreviations and symbols constitute an ever growing and important part of the language of the sciences. The use of one symbol or abbreviation for several different terms or meanings and the use of several different symbols or abbreviations for one meaning at present cause much confusion and often serious errors.

The conference was originally called by a limited group of engineering societies but after some discussion of the subject it was thought desirable to include as a part of the project the graphical symbols which are used in engineering drawings, diagrams, and the like, for representing instruments and apparatus and components of them. Here, it was thought advisable to obtain the co-operation of foreign standardization bodies in the work on account of the international character of much engineering and scientific work.

The work will go forward under a committee organization in accordance with the rules and procedure of the American Engineering Standards Committee.

Submits Tentative Standardization of Anthracite Names and Sizes

The Subcommittee on Standardization of Anthracite Sizes of the American Society for Testing Materials has prepared a tentative schedule of names, sizes and screen specifications for testing anthracite.

The following is a list of the names and sizes now used or used in the past:

ANTHRACITE SIZES, IN INCHES

	Round		Square						
	Through	Over	Through	Over	Slate, Per Cent	Bone, Per Cent	Total, Per Cent	Large, Per Cent	Small, Per Cent
Lump (Steamboat)	7	4½	6¼	4	..	..	..	5	10
Broken (Furnace)	4½	3¼	4	2¾	1	2	3	5–9	5–10
Egg	3¼	2¼	2¾	2	2	2	4	5	10
	3	2⅜	..	..	..	..	..	...	None
	..	2	..	..	..	..	..	...	.....
Stove	2¼	1⅝	2	1⅜	4	3	7	5	10
	2⅛	1⅜	..	..	..	.	..	...	None
	2	1⅜	..	..	..	..	..	...	.....
Chestnut (Nut)	1⅝	⅞	1⅜	¾	5	5	10	5	15
	1⅜	¾	..	..	..	..	..	...	.....
	1⅛	..	..	..	..	..	..	...	.....
	1	..	..	..	..	..	..	...	.....
Pea	⅞	9/16	¾	½	10	10	10	5	20
	¾	⅜	..	..	..	..	..	...	.....
	..	½	..	..	..	..	..	...	.....
Buckwheat	9/16	5/16	½	¼	15	15	15	...	15
	⅜	⅜	..	..	..	..	..	...	.....
	½	..	..	..	..	..	..	...	.....
Rice (Buck. No. 2)	5/16	3/16	¼	⅛	..	..	..	...	15
Barley (Buck. No. 3)	3/16	3/32	..	..	..	..	..	...	.....
		1/16	..	..	..	..	..	...	.....
Birdseye (Boiler)	5/16	1/16	..	..	..	..	..	...	.....
Culm (Slush)	1/16	3/32	..	..	..	..	..	...	.....

These are the sizes recommended by the subcommittee:

	Round-Hole Screens Through	Over		Round-Hole Screens Through	Over
Steamboat	7	4½	Pea	⅞	5/16
Broken	4½	3⅜	Buckwheat	9/16	5/16
Egg	3⅜	2⅜	Rice	5/16	3/16
Stove	2⅜	1⅝	Barley	3/16	3/32 or 1/16
Chestnut	1⅝	⅞			

Class 1 Railroads Consume 9,451,000 Tons Of Coal in February at $3.72 per Ton

Class 1 railroads of the United States consumed 9,451,000 net tons of coal during February, 1923, as charged to account 394, compared with 10,358,000 tons during the preceding month and 7,842,000 tons in February, 1922, according to a recent report of the Bureau of Statistics of the Interstate Commerce Commission covering 176 steam roads. During the first two months of 1923 these roads consumed 19,810,000 tons as compared with 15,968,000 tons during the corresponding period of 1922. The delivered cost per ton in February last was $3.72 compared with $3.55 for the corresponding month of last year.

Consumption of fuel oil during February totaled 135,537,000 gallons compared with 150,317,000 gallons in January and 110,679,000 gallons in February, 1922. The totals for the first two months of 1923 and of 1922 were 285,850,000 and 234,526,000 gallons respectively.

Handling and Testing Armatures

Careful Packing Especially Essential—Handling at Mines Should Be Done with Due Consideration of Dangers—Testing on Receipt of Armature Will Avert Considerable Annoyance and Expense—Methods of Making Tests

ALL reputable manufacturers and repair shops where armatures are either built or repaired have a regular system of testing them during the process of manufacture or repair and also upon completion. This is especially necessary with equipment used about the coal mines because of the severe conditions under which the armatures must work and the expense and inconvenience occasioned whenever one of them breaks down or must be taken out of a motor for any reason.

The reliability of such tests depends upon the persons conducting the test. For the most part these testers have become very proficient, due in part to the elaborate system of checking back upon any particular tester in case any equipment leaves the shops and is reported defective upon arrival at its destination.

There are so many important points to be considered in the handling of an armature around the coal mines that we shall single out only a few and give them our consideration.

Proper connections and insulation are the most important features in connection with all electrical equipment from the standpoint of maintenance.

The most delicate parts of a direct-current armature are the commutator and the coil ends, or turns. When lifting an armature special care should be taken of these parts and it is advisable to use a lifting band or sling whenever possible. A lifting band should be made of

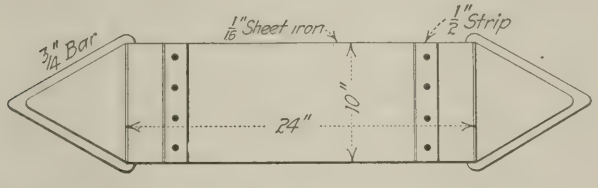


FIG. 1—LIFTING BAND FOR ARMATURES

The band is used around the body of the armature, thus forming a sort of hammock for carrying the armature instead of sliding or rolling it and causing damage to the winding.

sheet iron sufficiently flexible to be placed around the body of the armature as shown in Fig. 1. Such a lifting band is fitted with handles of sufficient strength to carry any weight to which the band may be subjected when lifting the heaviest armature.

If a sling is used it should be placed over each end of the armature shaft and a brace placed so as to prevent the rope from crowding against the commutator or coil turns, as shown in Fig. 2.

Great care should be exercised whenever an armature is boxed for shipment. Improper boxing of an armature being sent away for repairs has frequently increased the damage to the armature and necessarily the expense of the repair work which must be done.

The armature box used for shipping should be so constructed that the armature will be supported by its shaft, regardless of the position into which the box may be tipped during shipment. When the armature shaft is short and does not extend far enough outside the ends of the commutator bars, it can be extended by a short piece of pipe slipped over the end of the shaft. Care should be taken here to block the end of the pipe so that it cannot shift and thus allow the armature to drop.

To fasten the lid on the box it is always preferable to use screws, as their use gives the box greater strength, and they are more likely to be properly placed so as not to damage the armature. If nails or screws are used in the construction of the box, great care should be exercised so that they do not injure the winding on the commutator.

When moving armatures about the colliery, they should never be rolled, as such a procedure, although too common, aside from forcing particles of dirt, coal, metals or other foreign materials into the coils, also strains the laminated core, which shifts and chafes or cuts the insulation of the coils in the slots of the armature. The proper way is to support the armature shaft in a kind of cradle (as shown in Fig. 3), similar to a stretcher with two handles at each end. The armature should be further protected against moisture and mechanical injury from falling objects.

When a new or repaired armature is received, it should be unpacked at once and given a careful inspection and a thorough test. In some instances such a procedure discloses a fault which, if found in time, will not only prevent more serious damage but will also save the work and inconvenience of assembling an armature in a motor only to find it defective.

One of the first things to be done with a new or repaired armature is to look it over very carefully for any outward appearances of damage or wrong assembly. This inspection consists in examining the coils, which should not be broken, improperly insulated, or not well down in position. The commutator should be examined for high, low or rough spots, or short-circuited bars. The clearance of the coils when the housings are in place should be examined, and the shaft and bearings should be examined for a true fit. After this is done the armature should be tested for electrical faults. A test should be made for grounds in the coils or commutator, for short-circuits in the coils or commutator and for open circuits in the winding. The equipment necessary for the above-mentioned tests consist, in their simplest form, of a telephone receiver, a buzzer, a battery and a few pieces of wire. All colliery electricians should supply themselves with this simple testing set for any emergency. Let us assume we are going to test an

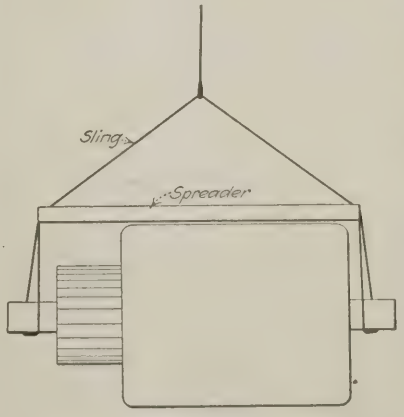

FIG. 2—ARRANGEMENT FOR SLING

The sling is kept from crowding into the commutator and coils by means of a brace. Frequently considerable damage is done by carcless use of chains and ropes used as slings.

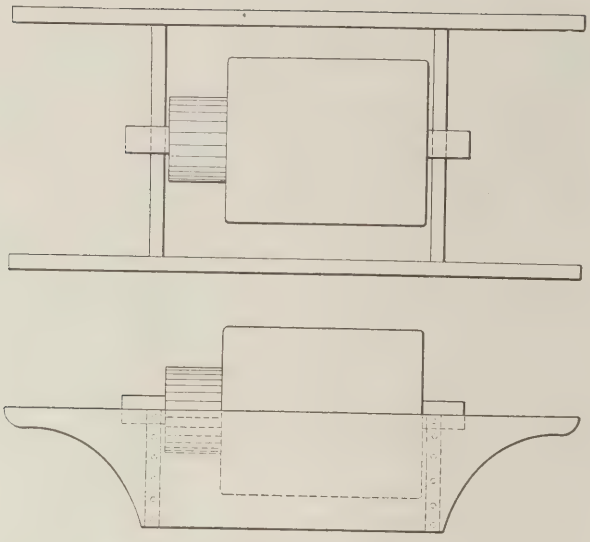

FIG. 3—ARMATURE CARRYING BOX

An unnecessary expense in repairs to armatures can be avoided by furnishing a supply of boxes similar to the above. These boxes can be used to transport armatures to all parts of the mines with reasonable safety.

armature for an open-circuited coil. This test is essentially the same as the test for a short-circuit coil. First of all we will connect a buzzer and battery in series as shown in Fig. 4; the free terminal of the buzzer and the free terminals of the battery are placed on the commutator say about 10 to 15 bars apart on the average commutator. As soon as this is done the buzzer will start to vibrate because the circuit is now closed through the winding on the armature; next the two terminals of a telephone receiver are put on two adjacent commutator bars about half way between the two terminals of the buzzer circuit. If the coil connected to the two bars to which the telephone receiver is connected is all right there will be only a slight vibrating sound in the receiver, because the receiver is shunted on the coil. If there is a loud sound in the receiver then there is an open circuit in the coil and the receiver terminals are not shunted by the coil, hence the loud sound in the receiver. If there is very little or no sound in the receiver then the coil or the two commutator bars are short-circuited. This test is carried on all around the commutator in this way until completed, always keeping the receiver terminals about half way between the buzzer circuit terminals as all four terminals are moved around the commutator during the test. If an open circuit is found it will be well first to examine the connections to the commutator bars, as the trouble may be there; otherwise the trouble will be found to be in the coil. If a short-circuit is found examine the commutator bars and see if the bars are short-circuited, especially at the necks of bars and at the mica between the bars. If necessary disconnect the coil from the commutator bars and test to find out whether the short-circuit is in the coil or in the bars.

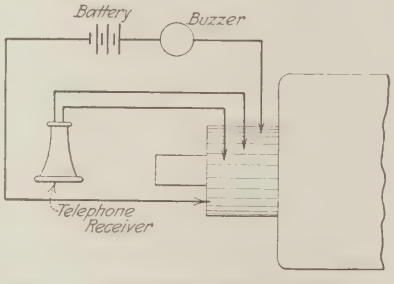

FIG. 4—TESTING FOR OPEN- OR SHORT-CIRCUITS

The bar-to-bar test will readily locate defects. Sometimes it will be necessary to disconnect the coils from the bars to localize the trouble.

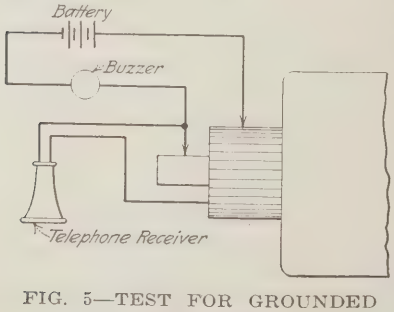

FIG. 5—TEST FOR GROUNDED COILS OR BARS

Grounds usually are easily detected, but sometimes difficult to localize. A little experience with this outfit will enable the operator to localize the ground by the variations of the sound in the receiver.

Fig. 5 shows the arrangement for testing the armature for grounds. Here the battery terminal is moved around the armature and when it comes to a grounded bar or coil the sound in the receiver stops or becomes very weak. In this way the grounded bar or coil can be located, and here again it is advisable to disconnect the coil from the bar so as to determine whether the ground is in the bar or the coil.

Would Organize Syndicate to Buy Cars and Apportion on Basis of Consumption

IN ANSWER to a question addressed to L. S. Evans, president of the Eastern Coal & Export Corporation, prompted by his article on ownership of coal cars (*Coal Age*, April 19, 1923), he has written the following comment:

"In reply to your letter of April 19, I am sure you are correct in saying that non-originating roads would not favor owning coal cars, and I do not blame them. So long as they can put this burden on the coal roads and collect revenue on coal tonnage carried in the other man's cars, they will be opposed to any plan having for its object the shifting of the financial burden to their own shoulders. The point is not the attitude of the roads, but the essence of the question is whether consumption or production is dominant.

"We have gradually come to view the railroads as facilities to give service to the public, rather than business enterprises promoted to pay dividends to investors. In consequence we have the Interstate Commerce Commission controlling the roads, with the public interest uppermost in their minds. On the other hand, purchasing of cars is left to the different roads, and is, therefore, made by and subject to the viewjoint of their owners. I mean that the railroads buy cars only when the pressure of necessity compels their purchase, and such pressure always comes after the needs of the public have exceeded the facilities of the roads.

"A way around a sudden reversal of the present practice would be the formation of a national car-owning company, contributed to by all the roads, which corporation or syndicate would buy coal cars as a pool and distribute them to the different roads on the basis of coal consumption thereon.

"The opposition of non-originating roads is in itself not an argument against the idea, and the point is to arouse discussion and have the opposing roads state valid reasons and facts to support their point of view. Something must be done in this country to remedy the defects in coal distribution, or the uninformed public, in conjunction with the ignorant labor unions, in the mass will bring about nationalization or some other form of socialistic control."

EVIDENTLY THOSE VICTIMS of that Herrin mob committed suicide.—*Greenville Piedmont.*

Screening, Dry Cleaning, Aspirating and Dust Collecting At Brilliant Mine in New Mexico*

Coal Under One-Inch Diameter Sized on Two Banks Each Consisting of Five Ascending Screens — Oversize Cleaned on Two Spirals — Coal Under One-Sixteenth Inch Aspirated—Minor Mechanical Difficulties in Operation

By F. A. Young
Chief Engineer, St. Louis, Rocky Mountain & Pacific Co., Raton, N. M.

ORIGINAL in most of its features is the dry-process cleaning plant built and operated by the St. Louis, Rocky Mountain & Pacific Co. adjacent to its mine at Brilliant, N. M. The equipment consists, primarily of screens for separating the coal into five different sizes all smaller than 1 in., an aspirator for preparing a sixth size and pneumatic machines each cleaning one of the six sizes. These machines are patented and were manufactured by Sutton, Steele & Steele, of Dallas, Texas., until a few months ago, when all the selling rights were acquired by the American Coal Cleaning Corporation.

These screens (see Fig. 1) are called anti-gravity screens because the coal travels uphill. The screens at Brilliant are 3 ft. wide and 7 ft. 4 in. long. They consist of one upper deck having a screen of wire mesh which slopes upward at an angle of 12 deg. in the direction in which the coal flows. Under this is a lower deck sloping in the same direction at an angle of 7 deg. and having a solid bottom. This deck advances the undersize to the next screen.

These decks are about 11 in. apart at the discharge end. Owing to the pitch in the lower deck and the fact that the undersize is carried upward it is possible to place any number of screens on a level floor, the coal from one screen falling a few inches onto the upper deck of the screen next in line. This is one of the most valuable features in this arrangement, for the coal does not have to be elevated or rehandled in any way.

The oversize may be taken off on either one or on both sides. The length of the screens corresponds to the proper spacing of the cleaning tables, which obviously are placed on the floor below. I know of no other screen which can be operated in this way. The coal is caused to travel by a reciprocating motion, a shaft with two eccentrics, one on each side of the screen, being placed under the screen at about its midlength.

The screen box is attached to the stationary underframe by means of cast-iron plates extending across its full width. These are placed at an angle, as shown, so that the forward motion of the eccentrics causes the screen box to rise as it moves forward and the backward motion drops the screen from under the coal, thereby causing it to advance. The coal, advancing over the screen cloth in this rolling or jumping motion, is sized most effectually. It should be stated here that accurate sizing is necessary for the success of the cleaning tables. The stroke of the eccentric is 1 in. and the speed 350 r.p.m.

The pneumatic cleaning table works on the principle that when a film of coal 1 to 2 in. thick, the individual pieces of which are nearly all of the same size, is placed on a flat perforated surface and a large volume of air passed through it, the lighter particles, which are the clean coal, soon find their way to the top of the film, whereas the heavier particles, or waste, remain on the bottom.

The machine is built with a perforated deck about 4 ft. square under which is an air chamber and air duct connecting with a fan which is part of the machine.

*Article entitled "Dry Cleaning Coal at Brilliant Mine," read before Rocky Mountain Coal Mining Institute Feb. 27, 1923.

Note—Headpiece shows dry-process coal-cleaning plant at Brilliant Mine, the trestle from the mines and the tipple. Note the conveyor shed by which the cleaned coal is returned by a belt conveyor to the tipple for mixing with the run-of-mine if desired. The cleaned coal also can be delivered from a storage bin to cars spotted at proper points alongside the building.

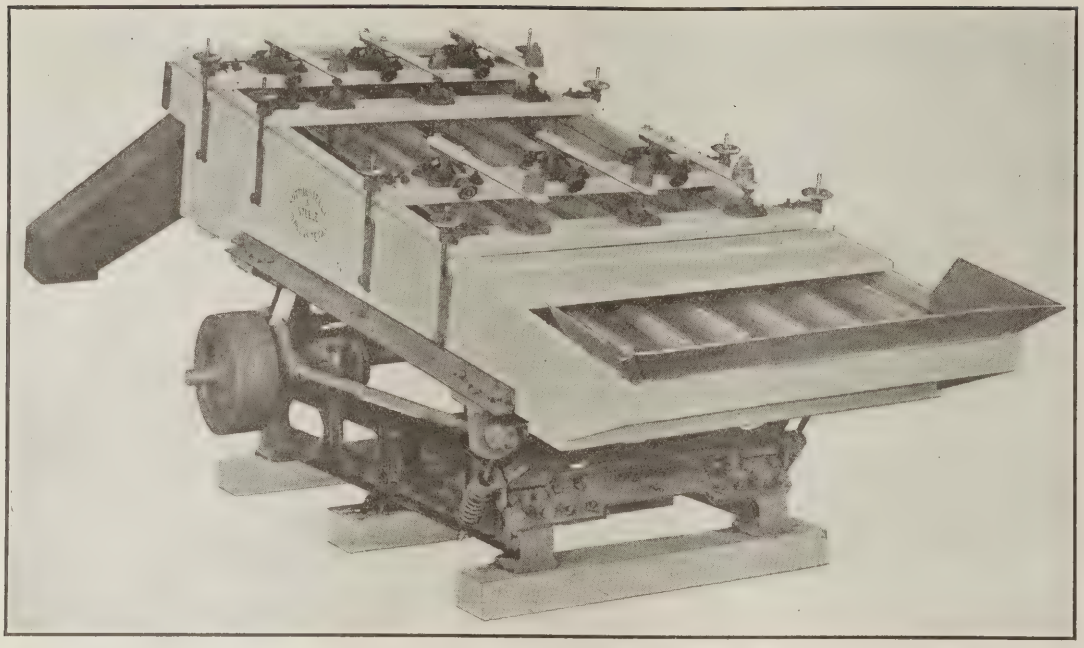

FIG. 1

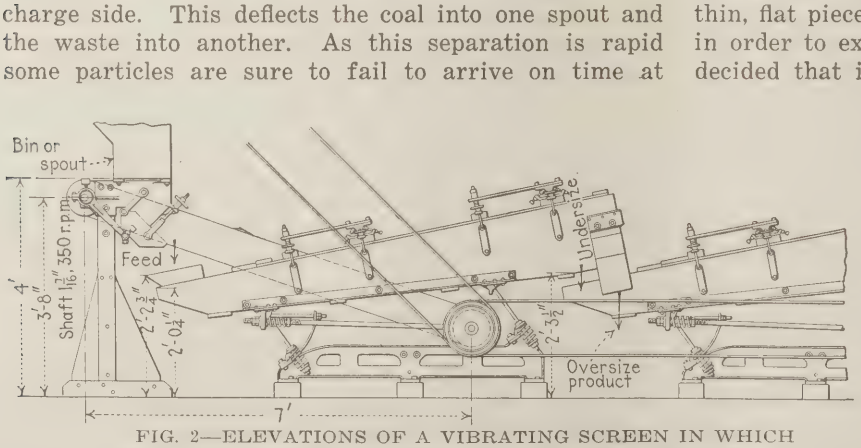
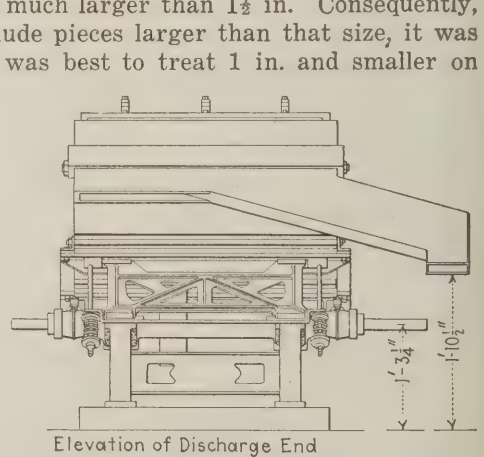
Screening Table

The lower or feed end of the table is provided with a guard plate so that the air will not be sucked in by the dust hood except from over the screen. The eccentric will be noted by which the screen is shaken in strokes of one inch amplitude. The eccentric shaft makes about 350 r.p.m., the number being variable at will.

The deck of the table has a reciprocating motion the same as that of the screens already described. This tends to advance the product up a slight adjustable slope. The coal is fed at one corner of the table as shown, and the deck slopes away from the feed and at right angles to the reciprocating motion. On top of the perforated deck are riffles about 2 in. apart, running parallel to the line of reciprocation. These riffles are about ½ in. high at the fan and feed side of the table and taper to nothing at the far side.



When coal is fed onto the table, the air passing through the perforations tends to raise it and roll it over these riffles down the slope toward the clean-coal discharge. The heavier particles do not get over the riffles as rapidly as the lighter ones, and the reciprocating motion is constantly pushing them toward the far side, where the waste is discharged. With these two actions constantly at work and tending in directions at right angles to each other and with the slopes in two directions nicely adjusted, a line is formed in a few minutes between the coal and the heavier particles, the line being near that side of the table which is opposite the fan.



A splitter board is readily adjustable along the discharge side. This deflects the coal into one spout and the waste into another. As this separation is rapid some particles are sure to fail to arrive on time at their proper position. For this reason it is advisable to make a third product, middlings, and this product is taken back and sent through the entire process for a second trial.

As this method of cleaning depends for its success on the difference of specific gravity between the coal and the impurity, it will of course work better when the refuse is slate or rock than when it is bone. There is, however, another important factor. Not only must the pieces treated be all of the same size but also all of the same shape. A slate impurity is sometimes thin and flaky, and in that case it is difficult to separate.

At our Brilliant mine the impurity is nearly all slate, some of it in thin flakes. At our Koehler mine the impurity is mostly bone. This material breaks into pieces of the same shape as the coal. In a full day's test run on Koehler coal we were surprised to find that it was cleaned even more effectually than that from the Brilliant mine.

This latter mine produces about 800 tons in 8 hours. Our intention was to clean in this plant such coal as would pass through a 1½-in. bar screen. This appeared by test to be about 75 per cent of the total output. It was known that these screenings would contain many thin, flat pieces much larger than 1½ in. Consequently, in order to exclude pieces larger than that size, it was decided that it was best to treat 1 in. and smaller on

Elevation of Discharge End

FIG. 2—ELEVATIONS OF A VIBRATING SCREEN IN WHICH OVER- AND UNDERSIZE BOTH TRAVEL UPWARD

In the early days of the industry the point of feed of a screen was much above the point of discharge. With the introduction of shaking screens it became possible to lessen the difference between them. Finally someone bolder than the rest, desiring to save tipple height, made the screen bed level. Here is a series of screens in which each screen is level with its predecessor but nevertheless is fed from it. To do this the undersize travels on an upward grade of 7 deg. and the oversize on a grade of 12 deg. The movement of the screen is only one-inch and the action one of vibration rather than of shaking. Each screen reciprocation is independent and out of step with the rest, thus vibrating the screen without excessive vibration of the structure in which it operates. Five screens are set in one bank, the undersize traveling from one screen to the next.

the pneumatic tables. The experience in tests made confirmed us in that opinion. In consequence two spiral separators were installed for cleaning the larger sizes.

The plant was planned to take the screenings direct from the tipple to the cleaning plant and to return the cleaned coal to the tipple either for mixing with the hand-picked lump to make a clean mine-run or for shipment as a stoker coal, all the cleaned sizes being combined for that purpose. In order that a belt conveyor rather than an elevator might be used to bring the raw coal to the cleaning equipment, the plant was placed 230 ft. from the tipple. A 30-in. belt conveyor 250 ft. long between centers and having a rise of 63 ft. takes the raw coal from the tipple to the plant.

This discharges into a revolving screen 5 ft. in diameter and 13 ft. long. The upper 8 ft. of this screen has 1-in. square perforations. The undersize drops into a 30-ton bin which supplies the anti-gravity screens. The lower 5-ft. section of the revolving screen has 1½-in. square perforations, and the undersize drops to a 5-ton bin which supplies the left-hand spiral. The oversize of the 1½-in. screen goes to another 5-ton bin which supplies the right-hand spiral. These three bins discharge at a point about 4 ft. above the screen floor, which floor is 48 ft. above the ground.

The anti-gravity screens are placed in two batteries of five each, 8 ft. 3 in. apart from center to center and equidistant from the center line of the building. The No. 1 screens are each fed from the 30-ton bin by a reciprocating feeder which delivers coal over the full width of the screen. These feeders as well as those for the cleaning tables are patented by Sutton, Steele & Steele. They admit of accurate adjustment and are satisfactory in every way.

The screen meshes are as follows: ¾ in., ½ in., ⅜ in., $\frac{3}{16}$ in. and $\frac{1}{16}$ in., the first two being square mesh and the other three "ton-cap." The oversize from each screen is spouted to a steel pocket of about one-ton capacity which is hung from the bottom of the screen floor beams. These pockets are directly over and spaced exactly to suit the cleaning tables on the floor below.

The coal from the two small bins is fed to the spirals by small shakers of the Parrish type. Spirals for cleaning bituminous coal have a bad name because they do not clean satisfactorily all kinds of bituminous coal. Before adopting them we visited a large plant in Illinois where the results seemed to us to be poor, and a small plant in Oklahoma where the results were good. Much criticism is heard at Brilliant, largely, I think, because the 25 per cent of bright clean coal of this size in the waste pile shows up quite plainly, whereas at a wet washer, where the presence of the coal in the refuse could not be seen but could be ascertained only by analysis, a waste containing an equal percentage of coal would be considered acceptable.

In spiral cleaning, as you know, the specific gravity of the materials has nothing to do with the results. The difference in the coefficient of friction makes the separation. On steel chutes coal slides more rapidly than slate or bone and by centrifugal force is thrown over the side of the spiral chute into the outer collecting spiral. The slate, as it travels only slowly, stays in the inner spiral to the lower end, which thus becomes the waste chute.

Remember that the material, particularly the waste, must slide and not roll. Therefore, if the impurities in any coal are inclined to be round or cubical in shape they cannot be removed by spirals. At Brilliant the impurities are largely thin, flat pieces of slate. In every full-day test we have made of Brilliant coal the spirals cleaned as well as the ¾-in. pneumatic table. One full-day run of Koehler coal showed equally good results. We lately tried cleaning 3-in. to 1½-in. nut coal from the Sugarite mine. In this test the results were not at all good.

The waste from the spirals is conducted in chutes to a cross conveyor where it combines with the other waste and is taken to the waste pile. The clean-coal discharge is so arranged that it can either be mixed with other sizes in the main clean-coal bin or diverted to a sep-

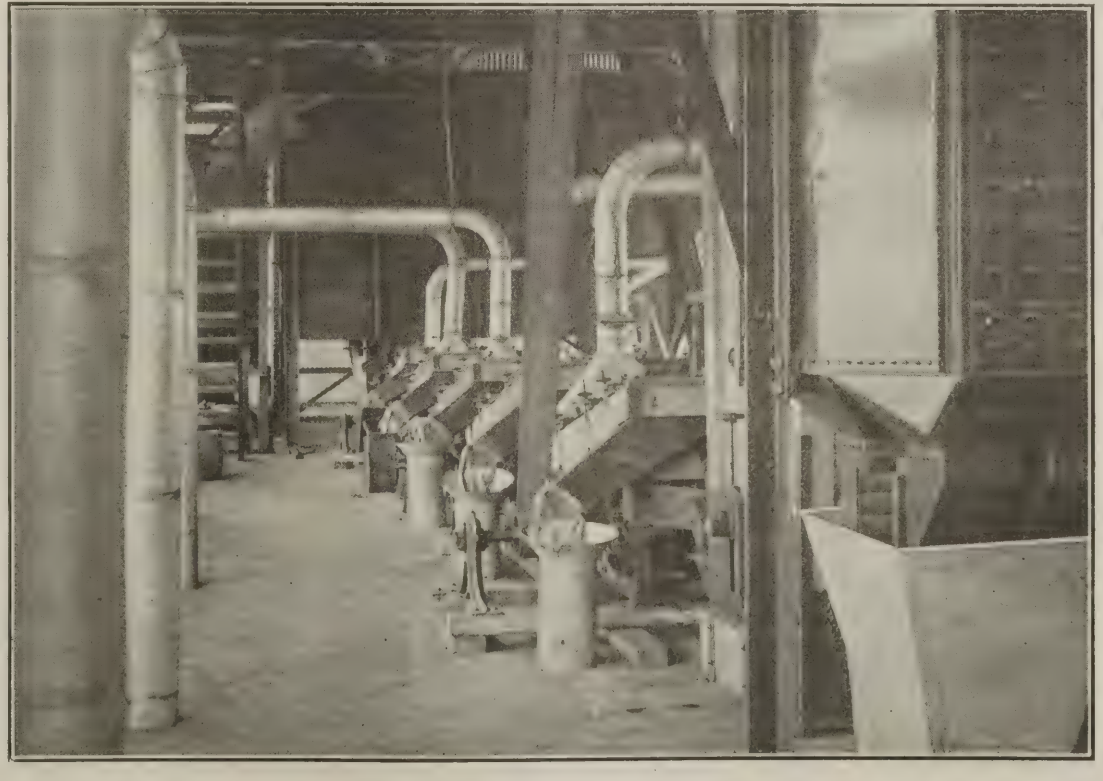


FIG. 3

Battery of Screens

The oversize is taken off at the upper end of the screen and goes by a chute spout to a vertical pipe leading to a small bin over a coal-cleaning table on the floor below, a cloth hood being used to prevent the escape of dust. It will be noted that dust-collecting hoods are placed over the point at which the undersize of the one screen is delivered to the top of the next for further screening.

arate bin on the other side of the building, from which it can be loaded into railroad cars as a pea coal.

To return to the anti-gravity screens, the last unit in each battery takes off the particles larger than $\frac{1}{16}$ in. At most mines it would not be worth while to screen or clean coal smaller than that, but at Brilliant this size contains more impurity than any other. It seemed to us easier to remove the dust from this last undersize by air than by screening.

Sutton, Steele & Steele make a machine for this which they call an aspirator. It consists of an inclosed chute 1 in. deep and 30 in. wide on a 50-deg. slope which joins another vertical chute which has the same dimensions at the junction point but is widened at the top and bottom, the top being converted into a 10-in. circular pipe which leads to a suction fan, the bottom becoming a discharge. The coal is taken from the undersize delivery of the last screen by a small bucket elevator about 12 ft. high and is delivered through an inclosed spout to the aspirator.

The fine coal thus joins the air current in a thin, wide stream. The velocity of the air at this junction slot is about 7,000 ft. per minute. Nearly all the dust below 60-mesh is removed. The coarser particles from 60-mesh to $\frac{1}{16}$ in. drop into a pocket over the No. 6 cleaning table.

The pneumatic tables occupy the floor below the screens. They are placed in two batteries, right and left, under the steel pockets as shown. The same type of feeder as is used as for the screens, but the feed is only 12 in. wide. This removes the coal from the steel pockets and delivers it to the tables. The table completely reciprocates 350 times per minute, each stroke being $\frac{5}{8}$ in. long, but a pair of cone pulleys provides adjustment so that the number of reciprocations can be increased or decreased about 50 strokes per minute. The fan for each machine has its own speed of operation. The speeds are as follows: No. 1 table, 1,040 r.p.m.; No. 2 table, 1,040; No. 3 table, 1,540; No. 4 table, 1,000; No. 5 table, 1,000, and No. 6 table, 900. As may be noted from the plan, the clean coal drops directly into a storage bin occupying the next lower section of the building.

The lower part of this bin is provided with gates and chutes for loading railroad cars alongside the building and on the underside are pipe outlets delivering to a belt conveyor which takes the clean coal back to the mine-run car at the tipple. This conveyor must stop when the tipple stops, and when this occurs the pipe outlets soon fill up at the belt and stop automatically. The middlings from both batteries of tables are delivered to a single belt conveyor which leads to a bucket elevator at the end of the building. This discharges into the 30-ton storage bin. The waste from each battery of tables falls onto a separate conveyor and each of these delivers to a cross conveyor which takes all the waste out of the building and delivers it to the waste pile.

This completes the description of the process except for the dust-collecting apparatus. It was known from the beginning that we would require such a unit; first, for the operation of the aspirators and, second, to free the building from dust. The one installed is manufactured by the Clark Dust Collecting Co., of Chicago, and is designed specially for our needs. It consists primarily of a 60-in. Claridge fan placed between two collecting cones, or cyclones, as they are often called.

The fan draws air from the sources of dust through headers and through branch pipes through the first cone and through the fan and then forces it through the second cone, discharging it to the atmosphere. The precipitation of dust is nearly perfect. The difficulty is to get the dust into the pipes. We tried to place dust hoods at all points where dust was liberated. These hoods will not get much dust unless the air enters at high velocity. The cross-sectional area of the hood opening must be no greater than that of its conductor pipe.

The pipe branches to the hoods generally were of 7-in. diameter and the hood 30 in. wide. Therefore the

FIG. 4

Coal-Cleaning Tables

Coal comes to these tables from the screens above, which are so spaced as to deliver the coal at the desired point. Three kinds of material are made on the table — coal, middlings and refuse. The middlings are taken back to the main feed bin, resized and given a second cleaning. This continues until they ultimately line up either with the coal or the refuse. In the end there is no middlings product, only clean coal and waste material

width of opening could be only about 1¼ in., but it is clear that a hood opening 30x1¼ in. will not reclaim dust from a wide area. We placed one hood at the discharge of the raw-coal conveyor, one at each anti-gravity screen feed, one at each screen discharge and one large pipe to each aspirator. On the cleaning floor one hood was placed at the feed of each cleaning table. The revolving screen had no dust hood, and we soon found that it produced much dust.

We partly inclosed it and placed a collector branch in one side of the housing. Though this improved the dust-collecting qualities, the hoods still do not collect nearly all the dust. At the cleaning tables the condition is worse. The hood at the feed collected much dust but a greater quantity was liberated after the coal had spread out on the table. To collect this is difficult, perhaps impossible. About 6,000 cu.ft. of air per minute comes up through the table deck. Even a 9-in. pipe and hood would take only about 1,500 cu.ft. Consequently the floor containing the cleaning tables is still a dusty place.

The application of power was planned as follows: On the screen-room floor a 50-hp. motor was placed which drove a line shaft running across the building on the level of the floor beneath the revolving screen. From this line shaft belts were run to the raw-coal conveyor, the revolving screen, the middlings elevator and the anti-gravity screen.

On the cleaning-table floor a 100-hp. motor was placed driving a line shaft on one side of the building. This in turn drove a similar shaft on the opposite side. These shafts drove the table fans directly through belts and, by means of countershafts, drove the shafts of the eccentrics on each table, the conveyors and the feeders. Separate motors drive the dust-collector fans.

The conveyor galleries and the main building are constructed entirely of steel and are covered with corrugated iron and lighted by windows having steel sash. A plant outside the building furnishes steam heat. The electric wiring is all in conduit with dustproof light sockets.

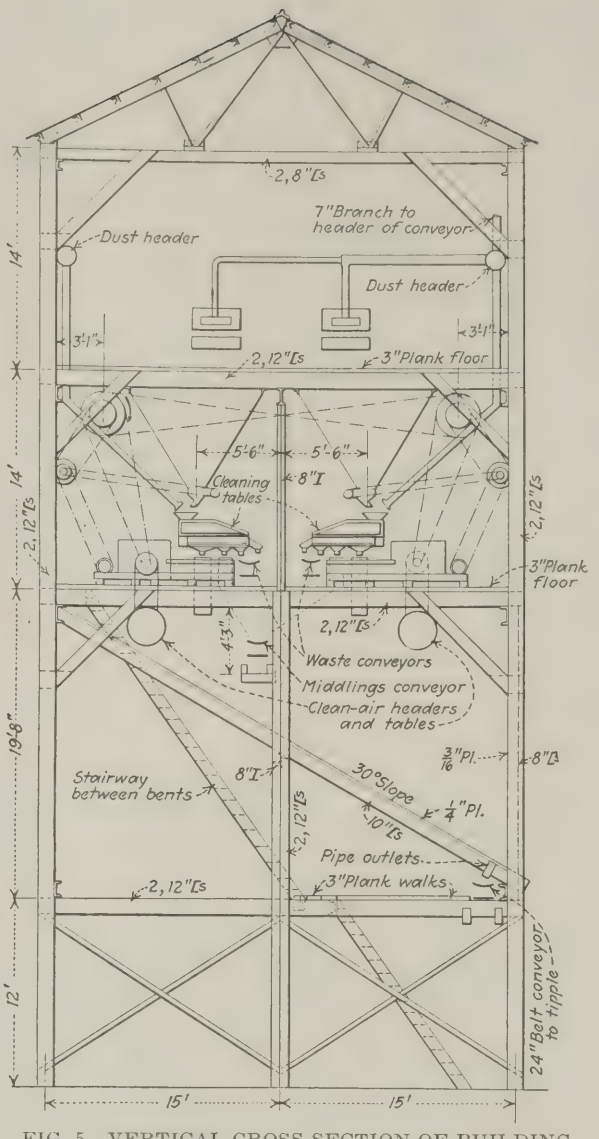

FIG. 5—VERTICAL CROSS-SECTION OF BUILDING

This elevation shows how the middlings and waste discharge of the tables are disposed of. The middlings and the waste each goes to its own conveyor. Note the almost vertical drives and the system by which clear air is taken to the tables and the dusty air is removed to the dust header.

Difficulties in Early Operation of Plant

From all this it might seem that the plant would work smoothly and without difficulty. Nevertheless there have been difficulties. First, these anti-gravity screens, although connected by chain drives to keep them out of step, cause much vibration. The floor beams of the screen floor were 12-in. I-beams 2 ft. 6 in. apart and of 30-ft. span. These were amply strong, but they had excessive vibration, so we ran a 12-in. I-beam under the center with 8-in. I-columns at each bent. This could be done, we found, without seriously obstructing the floor on which the cleaning tables operated.

Then, also, the dust was unpleasant and perhaps dangerous. Not only that, it stuck to the belts and pulleys and caused them to slip. Making the belts very tight caused great friction on the line shafts and nearly doubled the power required. You will note that the drives to the fans are not very good, being nearly vertical and having short centers. The main drive from the motor is not much better.

Not realizing at first that the friction of the tight belts would cause a great loss of power we put in another 100-hp. motor. Later we widened the belts and with less tension reduced the power to normal. The dust was still bad, so we installed another collector unit, dividing the headers between them. As the air was still dusty we covered all motors with airtight sheet-iron boxes or houses ventilated by intake and outlet pipes extending outside the building.

Then we were confronted with the greatest difficulty of all. The anti-gravity screens were supposed to operate at 300 strokes per minute and were so installed. At this speed the capacity was small. We had to increase the number of strokes to 350 to get 30 tons per hour with each battery. The eccentrics then began to break. We replaced them with wider and heavier eccentrics. Then the lugs to which the rods are attached began to break. We installed much heavier lugs, but then the pull-back springs began to break. The makers furnished heavier ones, but even now they often break.

The makers have devised and manufactured another screen of this type with a somewhat different driving mechanism which may be all right. If you buy any, first test them in an all-day run at full capacity. The cleaning tables work perfectly and never have needed repairs. All parts of the plant except the screens are now working satisfactorily.

As to the results of dry cleaning, the screens will

handle 30 tons per hour per battery and screen perfectly. Our experiences as to capacity of cleaning tables is as in Table I.

TABLE I—CAPACITIES OF TABLES AND SIZE OF COAL TREATED

Table	Size of Coal	Capacity, Tons per Hour
No. 1	1 in. to ¾ in.	12
No. 2	¾ in. to ½ in.	10
No. 3	½ in. to ⅜ in.	8
No. 4	⅜ in. to 3/16 in.	6
No. 5	3/16 in. to 1/16 in.	4½
No. 6	1/16 in. to 60-mesh	3

A fair average of cleaning is as in Table II.

If the dust were added to the clean product, as it would be in producing mine-run, the ash content would be 12.01 per cent. The ash in picked samples of clean coal runs from 8 to 9 per cent. Careful calculation from our analyses show that 72 per cent of the free impurity is removed. The quantity of waste is about 10 per cent of all raw coal coming to the plant.

At a dry-cleaning plant of this kind now being built at McComas, W. Va., each of the cleaning tables is to be operated by a direct-connected motor. This is in

TABLE II—PRODUCT RECEIVED AND DELIVERED BY TABLES

line with modern practice, but if you are going to build a plant do not forget about the dust. From our experience we conclude that a far better plan would be to place all motors outside the building and drive every unit from a line shaft.

The power required to run this plant is shown by meter readings to be 200 hp. Four men are required to operate it, a foreman and three laborers. The cost of constructing such a plant is perhaps 20 per cent more than for a wet-process plant. The cost of power is a little higher, but the labor cost is about the same.

There is, in my opinion, no good reason why this dry process should displace washing except in certain cases: First, if water is not available except at great cost; second, if the cleaned coal is to be shipped in railroad cars. In this case allowance would have to be made the customer for the water content, but someone would have to pay the freight on at least 6 per cent

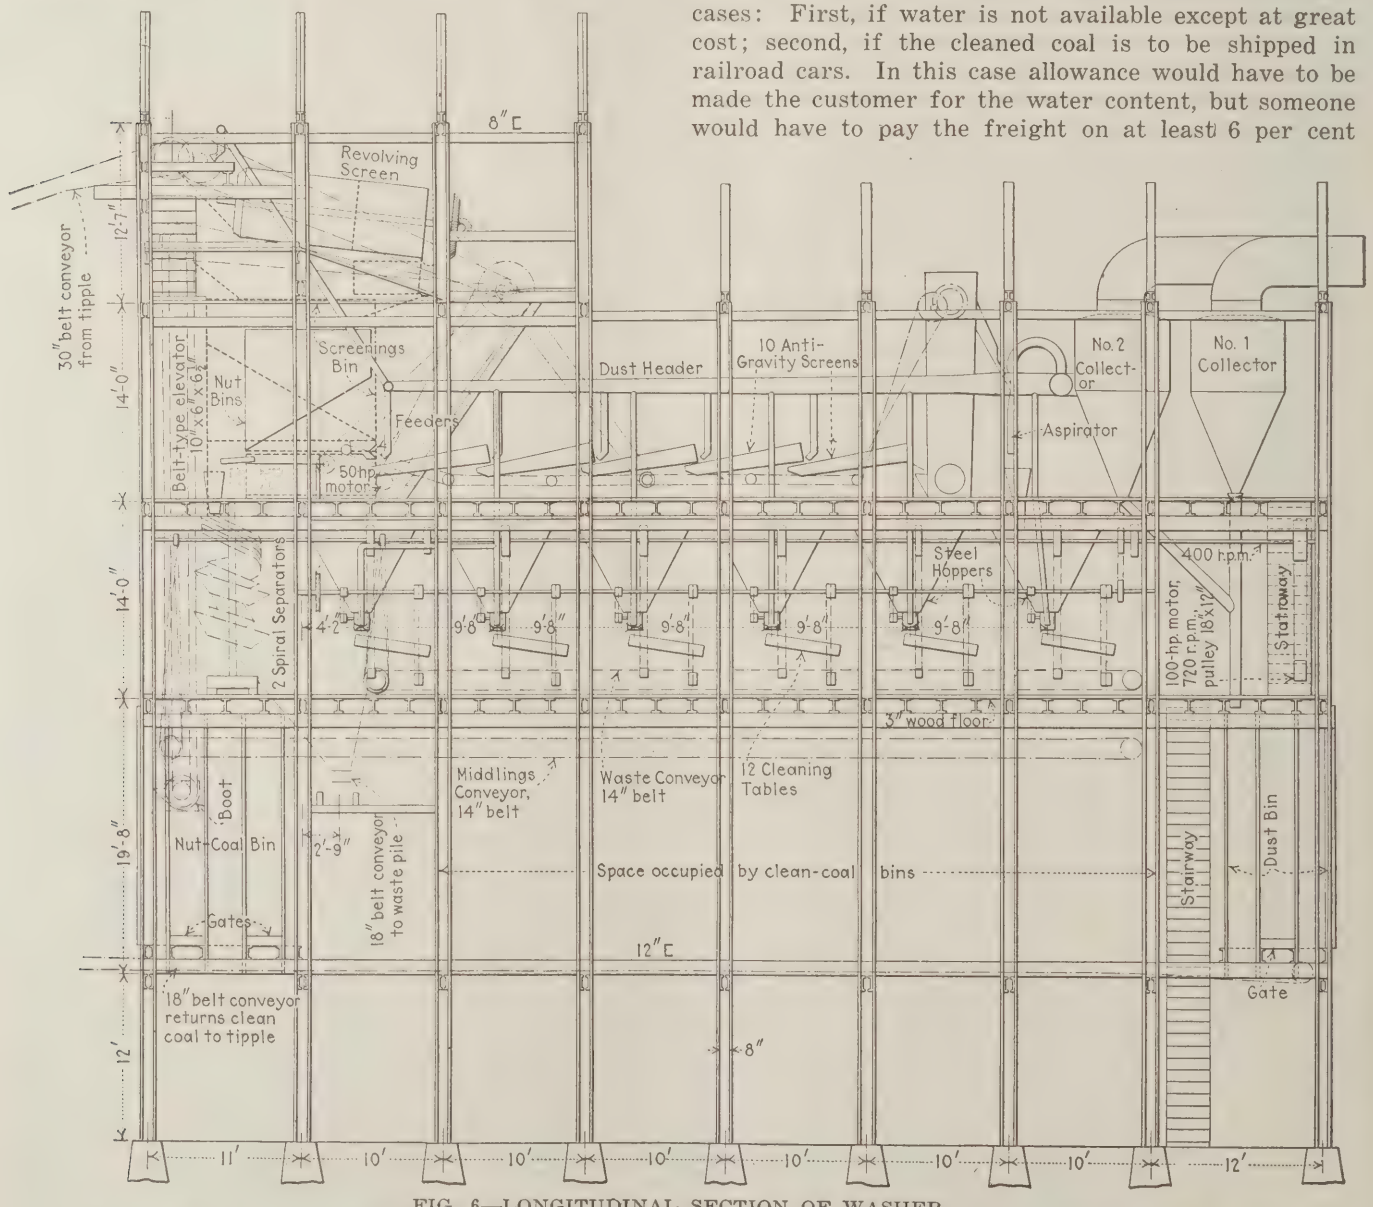

FIG. 6—LONGITUDINAL SECTION OF WASHER

This drawing shows the relation of the five screens in each bank to the six tables to which their product passes. It also shows the conveyors for middlings and waste. The space below the table floor is used for clean-coal bins. The system for removing dust also may be noted, as also the spiral separators and the drives.

of water. Third, if the coal is to be used at a powdered-coal plant. The size of coal prepared by the dry-process tables is finding an increasing market at plants which use powdered coal. At such plants fully half the machinery and more than half the expense is for drying the coal. At many mines such as Brilliant this dry-cleaned product if shipped in closed cars can go direct to the pulverizers without drying.

The steel structure and covering at the Brilliant plant was built by the Kansas City Structural Steel Co. after our plans and their own details. The conveying and transmission machinery and the revolving screen were furnished by the Link-Belt Co., and was, I think, perfect in every detail.

Paper Discussed at Rocky Mountain Session

At the completion of the paper, E. H. Weitzel asked what disposition was made of the middling product from the tables. Mr. Young stated it is sent back to repeat the process, over and over again, in a closed circuit, until it finally passes to the clean coal or the waste pile. In reply to a question by F. W. Whiteside, Mr. Young said the spiral could not handle wet coal. This agreed with Mr. Whiteside's experience, that as long as the coal was dry the spirals worked, but when the coal was wet they were no longer efficient. Mr. Young said the spirals are adjustable for various temperatures.

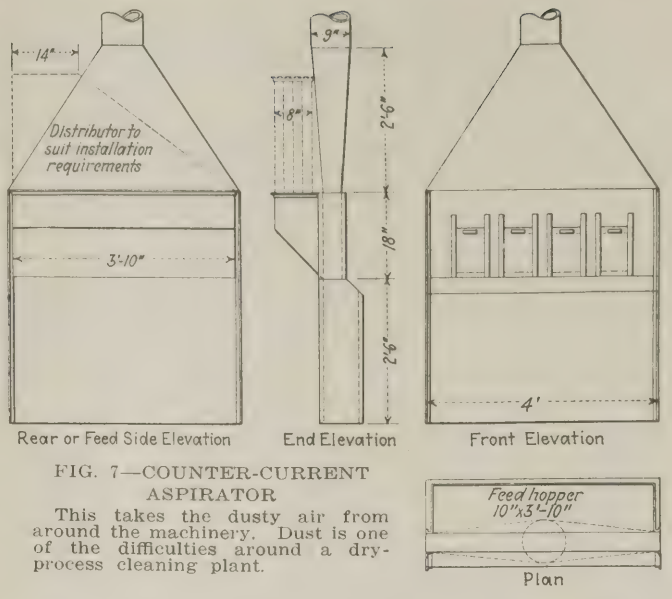

FIG. 7—COUNTER-CURRENT ASPIRATOR

This takes the dusty air from around the machinery. Dust is one of the difficulties around a dry-process cleaning plant.

Bureau of Mines Now Has Leasing Branch: Changes in Personnel

Continued growth of the U. S. Bureau of Mines, especially in the supervision of leasing operations on public lands, has resulted in the creation of a leasing branch within the bureau, the appointment of another assistant director, and several changes of personnel within the organization.

General operations under the leasing act of Feb. 25, 1920, development of lands in the naval reserves, and the supervision of operations on Indian lands have combined to make the federal government an outstanding factor in the production of minerals. Wells drilled on public lands, including the naval reserves, now produce approximately 3,000,000 barrels of oil monthly, or at a daily rate of 100,000 barrels. This production is outside of that from Indian lands. Coal leases and prospecting permits have been issued in fourteen Western states, in which the federal government is supervising the operation of 89 mines.

A. W. Ambrose, assistant director, has been placed in charge of the newly created leasing branch. He also will act as a consulting engineer to all branches of the bureau on matters relating to petroleum and natural gas.

D. A. Lyon, chief metallurgist and supervisor of stations, has been appointed assistant director in charge of the research branch, which includes the functions and scope of the former investigations branch after the elimination of leasing matters. For the present no appointment will be made to the position of supervisor of stations and Mr. Lyon will perform the duties of supervisor in addition to those of head of the research branch.

T. T. Read, having asked to be relieved from his position as chief of the information service and assigned to investigative work, has been appointed a supervising mining engineer. During the absence of F. J. Bailey, assistant to the director, on a visit to the mine safety cars and stations, Mr. Read will serve as acting head of the operations branch of the bureau and will later be assigned to appropriate field duties.

C. E. Julihn has been recalled from service as chief mining engineer of the War Minerals Relief Commission and made chief of the information service. Francis Winslow, now connected with the division of war minerals supply, has been assigned to serve with the War Minerals Relief Commission as chief engineer. J. W. Furness, who has been working with the war minerals supply division of the Bureau of Mines, has been given a permanent appointment in that division.

All of these changes and appointments became effective as of March 1, 1923.

How About Federal Ownership of Flivvers?

If Henry Ford believes in government ownership of railroads because the people should control their own transportation does he also believe in government ownership of automobile factories for the same reason? P. H. Greenlaw of the Fifth and Ninth Districts Coal Operators Association, in St. Louis, Mo., wants to know. He can't seem to get Henry Ford to answer, in spite of his best efforts to melt the wires between St. Louis and Detroit, Mich.

It all started when Mr. Ford was quoted sensationally about railroads and coal in the May issue of a magazine from the Hearst yellow presses. Among other things Mr. Ford was made to say: "No people can be free and go unrobbed who lack the power to move about and have their goods moved about without making terms with private interests." Reading this argument for government ownership of railroads, Mr. Greenlaw began bombarding Detroit with queries. He wired asking if Mr. Ford had been correctly quoted. Mr. Ford's first secretary replied he knew "nothing regarding statement reference to your telegram." Whereupon Mr. Greenlaw tried again, asking further if Mr. Ford favored government ownership of the automobile industry as well as railroads. Mr. Ford's second secretary replied that Mr. Greenlaw should write Mr. Ford a letter about it.

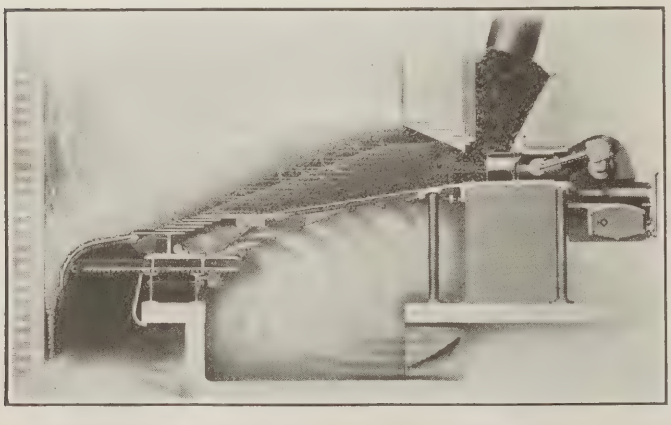
Mr. Greenlaw wired again and marked it "Personal." This time he said: "My inquiry needs no elaboration. It is simply: 'Are you in favor of government ownership of the automobile industry?' You surely would not advocate government ownership of property belonging to other people and be opposed to government ownership of an industry that enables one individual to pile up the wealth and power that the automobile industry has enabled you to secure." No reply. Mr. Greenlaw waited two days and then despatched another one saying: "Do you decline to commit yourself?" Still no reply.

So the country remains in ignorance of whether Mr. Ford would like to turn over his factory to the government along with all railroads so that the people "can go free and unrobbed," because they would then have "the power to move about and move their goods about without making terms with private interests."

Choosing and Operating an Underfeed Stoker

Light Firing at Short Intervals Early Found to Give Best Results—Equipment for Steam Plant at Mine Must Be Able to Meet Sudden and Wide Variations in Demand

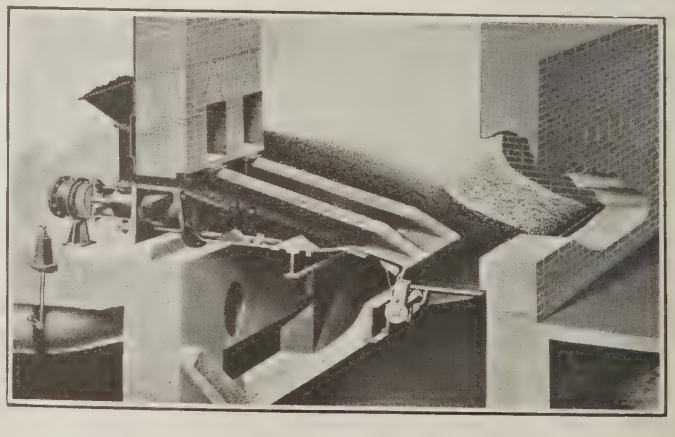
OUT OF THE industrial revolution which took place in England during the eighteenth century came a number of basic inventions, many of which were in connection with the generation and utilization of steam. The improvements of the steam engine encouraged efforts to develop machines to be driven by it, which in turn called for improved means of generating steam. It is not surprising, then, to learn that the first stoker was introduced into England by Brunton back in 1822, over a century ago. We are perplexed, however, by the tardiness of industries in adopting the mechanical stoker. Only in the past few years has it been recognized as an aid to efficiency.



Steam is most extensively used in the railroad industry, where it is a direct agent of motive power, and it is here that one must turn for early methods in its generation. In the early days of little power and small trains light firing at short intervals was discovered to give best results, and it finally struck the locomotive fireman that his job was not to see how much but rather how little coal could be shoveled into the furnace and yet obtain satisfactory results. This led to the practice of loading several scoops of coal just in front of the furnace door, followed by the pushing ahead and the breaking up of the caked mass to allow a replenishment of fuel at the door. To this day the method of hand firing the locomotive has not materially changed, and this so-called coking method of hand firing furnaces was used in many industries prior to the introduction of the stoker.

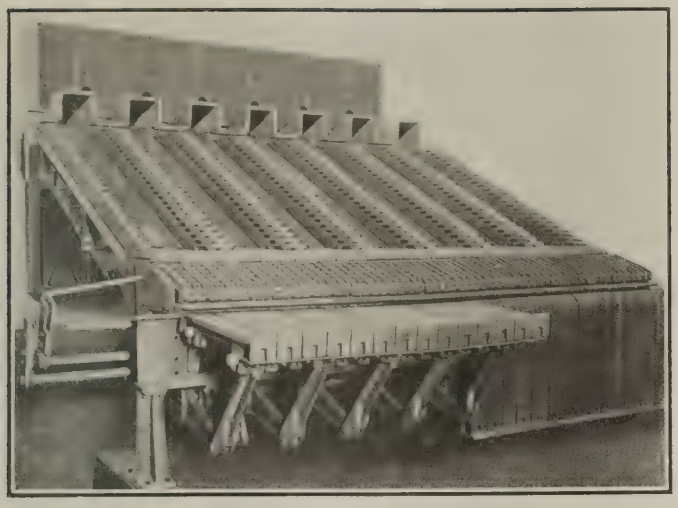
It was learned also that to load coal into a furnace promiscuously was to defeat the end desired—a uniform temperature—and that the stack loss is increased because combustible gases arising from the fuel bed are only partly burned and because the temperature falls when the flames are smothered. As a consequence, the pressure of the steam drops correspondingly. For bituminous coal good practice calls for the depositing of fresh fuel on bright spots in the fuel bed, as these are indications of a local thinning out; and if best results are to be obtained a level bed of uniform thickness must be maintained. In reality this is a checkerboard system of hand firing and no existing stoker has analagous principles of operation which demand the human element for success. Hand firing by spreading had a large following where anthracite was used. In this system the coal was scattered in thin layers over the entire fuel bed, and it produced excellent results because clinkering was not a serious problem in the combustion of anthracite.

There still remains one other scheme of firing furnaces by hand which was used to a limited extent in the early days, and that is the alternate, or side-firing, system, wherein the fuel bed is divided from front to rear into two sections which are alternately fired and cleaned, so that while one half burns intensely the other half is comparatively green and passing through the process of coking. The side-feed inclined stoker operates on a modification of this principle in that it has two fuel beds independent of each other.



As in choosing a particular type and capacity of mine pump to meet a given condition in a mine or in selecting different types of motors under different circumstances, care must be exercised in the application of mechanical stokers to the needs of the boilers, depending upon the demands of the plant. Economy cannot be obtained by correct operation of the stoking mechanism itself, to obtain the best results other factors must be in harmony, such, for instance, as a unit properly proportioned to the boiler and the load demand. Under one set of conditions a chain-grate stoker might be advisable and the use of any other type would be a misapplication likely to end in failure. Under other conditions the chain-grate stoker should not be considered. Many of the troubles encountered in steam plants may be attributed to incorrect design, and to guard against these is the duty of the engineer. After a careful survey he should decide upon the particular type of stoker which best meets the conditions.

Thus at a plant with a fairly uniform load through-



RILEY STOKER, IN WHICH THE RETORTS RECIPROCATE

This stoker is singular in that the entire grate area is adjustable and movable. Reciprocating motion of a steam plunger is transmitted from a wrist pin by connecting rods to the bearing bars. The retort, overfeed grate and ash tray alike reciprocate.

JONES A-C STOKER HAS NO OVERFEED GRATE

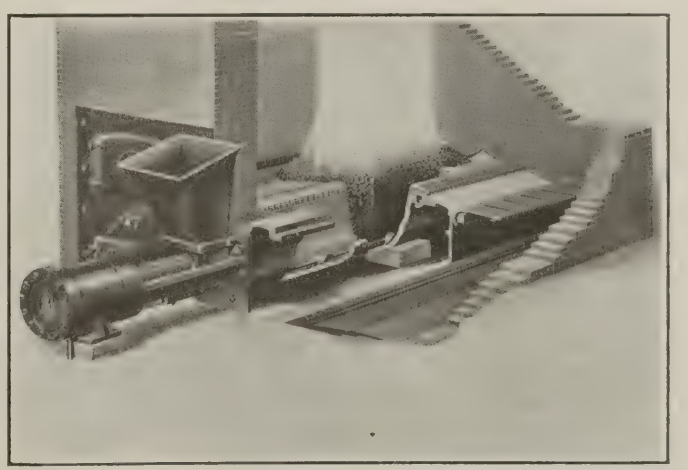
Movement and agitation of the fuel is dependent upon pusher blocks connected to the steam rams. The distinctive feature of this stoker is the automatic control of fuel and air effected by auxiliary devices.

TYPE H TAYLOR STOKER ADAPTED FOR COMBUSTION OF LOW GRADE FUEL

Reciprocation of the extension of overfeed grate is effected by the same mechanism which moves the rams. A steam cylinder imparts quick motion to the dump plate, loosening the clinkers which adhere to it.

out the day only a small excess rating is required as compared with a plant where the demand rises and falls in a twenty-four hour period, as in a mine plant. Here economy calls for a large enough but not too large a plant, and in the design allowance must be made for day-to-day variations in demand as the mine is further developed or the production is more or less than normal. The plant must be designed to minimize expenses in adding new units and at the same time provide the utmost simplicity of operation. The proportionate horsepower increase as a ratio of increase over total demand from period to period as the mine workings are extended is greater at a mine generating its own power than the proportionate horsepower increase in a large commercial power plant. In the latter case the load factor usually tends to become better, especially where the industries served are of different characters with respect to load.

In the selection of an electric motor the first quality to be investigated is its performance characteristics; likewise in looking about for a stoker to meet the needs at the mine plant, for the same reasons, one should study its application characteristics. The application of the same stoker to different types of boilers, even of the same horsepower, will produce different results. First the stoker must be chosen, then a boiler must be selected, and finally the furnace must be designed to derive the greatest efficiency from both. The three parts that go to make up the whole—the boiler, the stoker and the furnace—must be correctly proportioned to one another. For instance, it is much easier to proportion a boiler and furnace having the type and size of stoker in mind than it is to select the stoker after having decided upon a boiler and designed the furnace; in other words, as in the building of a house, the basement must precede the roof in construction. The application of a stoker to an old installation of a hand-fired boiler furnace often develops embarrassing difficulties that are not easily overcome, and great care should be exercised to obtain as nearly correct proportions as possible; otherwise poor plant operation will follow and the blame will be placed upon the stoker.



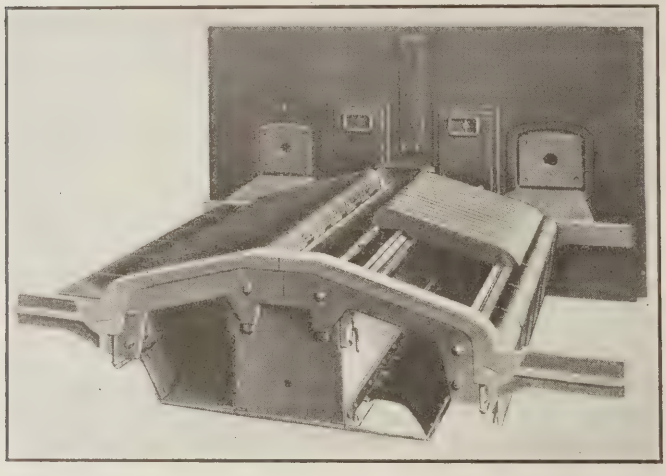
Another factor that must be considered when selecting a stoker is the fuel supply—the kind and grade of the coal to be burned must be taken into account. Those coals which have a tendency to cake burn better in a stoker which agitates the fuel bed in a manner to prevent caking; in extreme cases of caking forced draft may be needed to insure sufficient air for complete combustion. On the other hand, there are coals which do not have that tendency to mass. If these are introduced into a furnace having a stoker that agitates, best results are not obtained, as the fines are unduly sifted through the grates. The free-burning coals of the Middle West do well on the chaingrate stoker chiefly because it is not unduly agitated. The high ash content of these coals combats free agitation, and relative advancement from grate bar to grate bar is well nigh impossible with some of these, hence in this instance the traveling grate is best.

As we will deal with only one type of stoker in this article, the underfeed type, the application of several kinds of coal will be mentioned only as concerning this one type of stoker.

Of the three types of stokers, the underfeed stoker undoubtedly gives the best results when burning the low-volatile coals such as those of Pennsylvania and West Virginia. They are comparatively low in volatile matter and high in fixed carbon; they tend to cake in large masses in the early stages of combustion and consequently require agitation for efficient combustion. Extensive tests by the U. S. Bureau of Mines have proved that the greatest percentage of these coals have high fusing temperatures, for which reason agitation is not likely to cause clinkering trouble.

The valley-and-hill design of underfeed stoker with its retorts flanked by tuyere boxes affords a favorable condition for the burning of these coals. With a forced draft the fire may be thickened with less danger of its contents massing. The natural swelling and caking properties of these coals cause them to expand upward on heating. The simultaneous action of the air forced from the tuyeres and the lifting of the fuel in the retorts by the movement of the pushers does not afford an opportunity for extensive caking. Because the content of volatile matter is low the combustion is fairly complete in the fuel bed itself and consequently the heating surface is closer to the flames than is the case where high-volatile coals are burned, as the latter require more space above the fuel bed for ignition of the gases given off.

High-volatile coals with a moderate ash content also possess the caking property characteristic of the low-



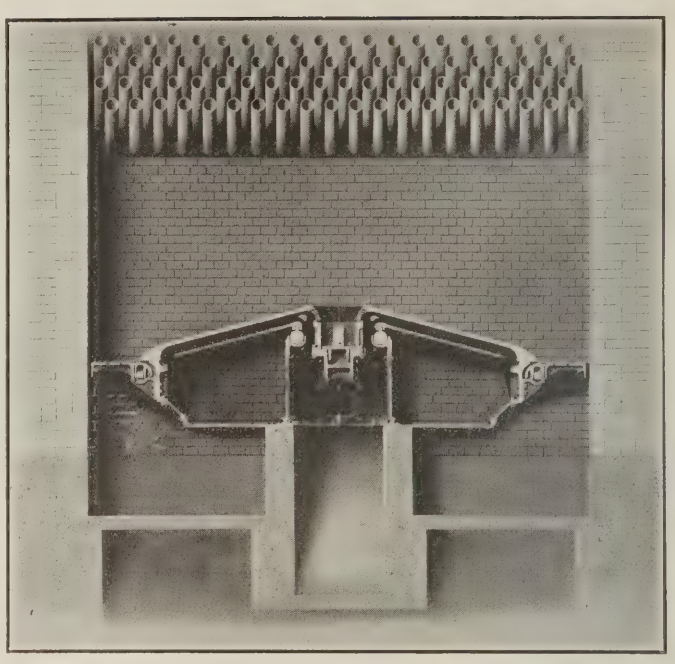
JONES SINGLE-RETORT UNDERFEED STOKER

Fuel is forced backward and sidewise by pusher blocks onto sloping combustion grates and then to hand-operated dump trays. The stoker is self-cleaning and simple in construction.

volatile coals but to a lesser extent. The thick fuel bed in the underfeed type of stoker furnishes an ideal condition for the distillation of the hydrocarbons. For this reason combustion is efficient and little smoke is made. However, the ash must be dumped at more frequent intervals because there is more of it.

One other kind of coal representative of major production in the United States, the high-ash coal coming from the West, having an impurity content varying from 6 to 30 per cent ash, presents problems in combustion depending upon its ash content. In the main it is a free-burning coal which tends to clinker, especially at high combustion rates, and to overcome this some means must be provided to prevent the adhesion of clinkers to the grates and brickwork. Best results are obtained by providing a continuous means for disposing of the ash, as, for instance, with a clinker grinder.

The working principle of the underfeed stoker is as follows: Fresh coal is fed upward and forward into the fuel bed by a pushing agent, usually a steam-operated ram. The fuel bed is made up of three layers which specifically may be called the green-coal zone, the coke zone and the incandescent zone. In the middle zone the volatile matter is "cooked" off and in the upper zone it is burned. Boiler ratings from normal to as much as 400 per cent may be obtained with the underfeed stoker.



TYPE E STOKER SHOWING GRATES

This stoker has been perfected to control firing readily by means of a compensating-type damper regulator connected to a steam-driven engine, thus giving automatic operation.

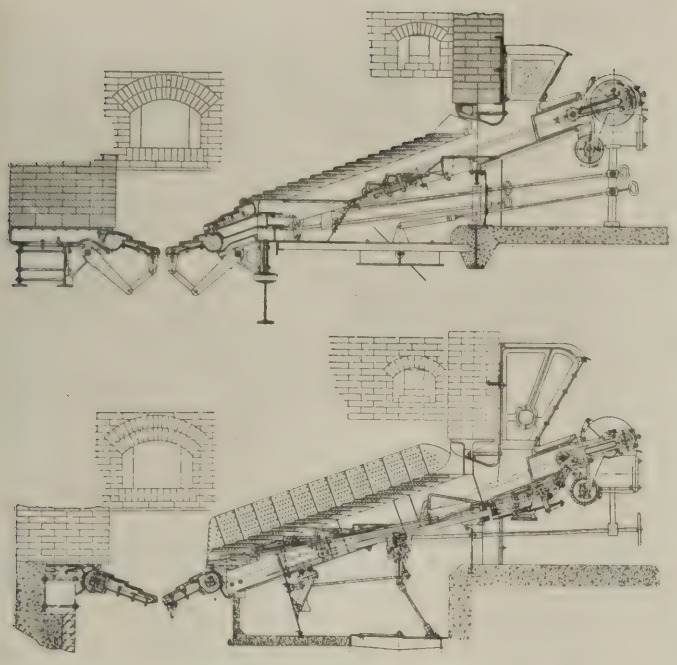
Underfeed stokers are classified as single-retort and multiple-retort stokers. The former is best suited to boilers of small horsepower, not to exceed 350, and is applied to advantage to boilers which are set low and have no ashpit under them. Combustion may be completed with or without the aid of an ignition arch. The multiple-retort stoker provides a higher combustion rate per square foot of grate area and consequently will sustain peaks above boiler rating higher and for much longer periods than will the single-retort stoker. In addition to these merits the furnace temperature is more uniform and less floor space per horsepower is taken up by the multiple-retort than by the single-retort stoker. The latter, however, has an application in the smaller plants and may be applied to an old boiler more readily than the former.

Perhaps the simplest of stokers belonging to the single-retort class is the Jones standard side-dump stoker. On either side of the single retort are side

SECTIONAL VIEW OF TYPE E STOKER

Shows arrangement of ashpit and draft, also the relative position of grates with respect to the boiler tubes.

plates which support the fuel bed overflowing from the retort. Air from a blower travels to the fuel bed by way of a sealed ashpit, under ribbed dead plates, and thence through the tuyeres.



The outside equipment consists of a feed hopper to which is attached a steam cylinder operating the feed ram. Steam is admitted behind the piston and pushes the ram ahead and thus carries with it a portion of the coal to the retort, after which it is further relayed ahead by pusher rods.

The feature in the control of this stoker is the automatic steam control regulator on the steam line leading to the engine, which governs the speed of the engine and thus controls the speed of the fan and the feed of the coal to the retort. In this way an even pressure of steam is maintained and constant relation is sustained between the coal and air supplied for combustion.

With a small amount of brickwork and excavation for the ashpits this type of side-dump stoker may be installed under many types of boilers. The ashpits extend 6 to 18 in. below the floor line, depending on local conditions, and fuel is burned efficiently without combustion arches.

Retaining the simplicity of the Jones single-retort stoker, yet developed so as to preserve the merits of the multiple-retort design for large loads, the Jones A-C stoker differs from the other underfeed stokers which will be described.

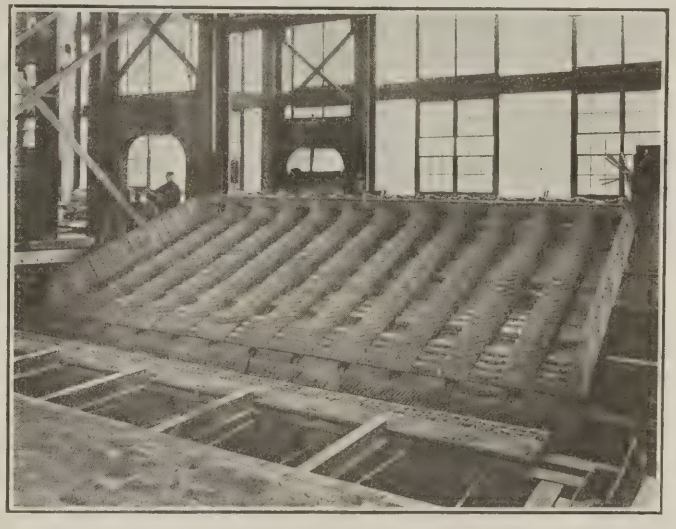
Into a steam cylinder is fitted a piston to which in turn is attached a ram. When steam is admitted into the cylinder through an automatic control valve, the ram is withdrawn from the retort and coal drops in front of it. The operating mechanism is timed so that the valve reverses the flow of steam and the ram pushes the coal from the bottom of the hopper into the retort. The fuel already in the retort is pushed upward and ahead by pusher blocks fastened to auxiliary rams. Agitation of the fuel bed is accomplished entirely by these means. The overfeed section behind the retorts is not movable. The dump plates are made in sections which are hinged to a shaft running parallel to the

WESTINGHOUSE STANDARD AND NEW MODEL TYPES
Fuel is delivered to the grates by means of a cast-steel ram, shown under and just to the right of the hopper. Note that the overfeed grates are operated through a rod driven by the same mechanism that operates the feed ram.

rear of the overfeed section and are dropped toward the bridge wall by a control lever at the side of the stoker.

Other details are as described in the single-retort stoker of the same make. The control valve, which permits eight rates of operation, has already been described. In the multiple-retort type, however, a deep ashpit is employed together with necessary air compartments for forced draft.

Another stoker which strictly belongs to the single-retort class is the Detroit underfeed stoker, whereby coal from the feed hopper outside the furnace is fed ahead through the entire length of the retort. This ram is driven from a crank connected to a drive shaft and consequently its stroke is regulated directly by adjusting the length of the connecting rod. Likewise the rate of feed may be regulated by suitable adjustment.



Like the Jones stoker, the sides of the retort are mounted by tuyere blocks alongside of which are ribbed grate plates. Burned-out ash is deposited upon solid dump plates which are dropped by a lever mechanism controlled from the front of the stoker. Forced draft is used in combustion. The blower directs air into sealed compartments and thence through unit sections of tuyere blocks to the fuel bed.

In the Roach single-retort underfeed stoker coal is fed to the stoker in the usual manner from a feed hopper by a steam-operated ram. In addition to the pushing action of the ram in the retort, the fuel bed is further agitated by reciprocation of inclined sectional side grates. The motion of these grates is adjustable to conform with the rate of combustion desired.

The side grates serve a dual purpose in that they agitate the fuel bed and, by reason of their hollow construction, act as conductors of air from an air chamber to the faces of the retort. Air for combustion is admitted to the combustion chamber under a high and a low pressure. The high-pressure air chamber is located under the low-pressure chamber and supplies the forced draft to the tuyere grates and also supplies air to the low-pressure chamber above it through a bleed-off valve which is controlled from the front of the furnace. This low-pressure air aids combustion by passing upward into the fuel bed on the grates through their interstices.

The Combustion Engineering Corporation builds single, double and triple-retort underfeed stokers, all of which in reality are of one type. They differ from each other only in so far as proportions and strength of construction are concerned. The double and triple-retort types, like the single, are known as the Type E stoker and are double and triple duplications of the single-retort stoker set side by side in one chamber.

Either coal-conveying machinery or hand labor delivers the coal into the stoker hopper, from which it is fed the full length of the retort by means of a reciprocating plate on the bottom of the retort. Then the coal is further distributed by auxiliary pushers attached to the bottom plate and alternate-moving fire bars which

CONSTRUCTION VIEW OF NEW MODEL TYPE
The ends of the rams are plainly seen and also the necessity for a wide hopper and ashpit.

form the side grates and carry the ash to dumping trays on either side of the side grates. These fire bars alternately are movable and fixed. The dumping trays are operated from without by a ratchet mechanism.

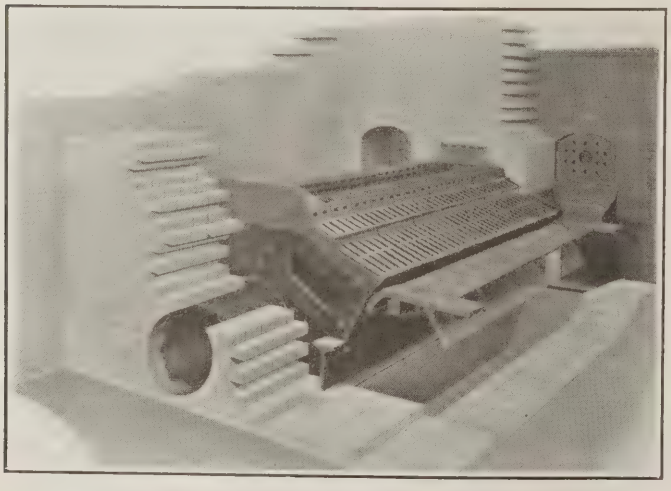
Air from the blower is conducted through a duct to the wind box located directly beneath the retort. From there it passes upward through tuyere openings in the retort end of the fire bars while the remainder passes through the hollow bars and is conducted to auxiliary air boxes under the grates. From the air boxes the air is vented to the fuel bed through slot openings between the fire bars.

Like the Jones stoker, the Type E stoker is automatically controlled by a compensating-type damper regulator which is sensitive to minute variations in steam pressure and connects with a throttle-valve on a steam driver or a rheostat on a motor.

In details of design and operation the Westinghouse underfeed stoker of the multiple-retort type is distinctive. The coal hopper is unusually large, being practically equal in length to the width of the furnace. Coal is delivered into the retort by a ram connected to a cast-steel crankshaft which is driven by a worm gearing.

To guard against damage, should foreign substances be admitted accidentally with the coal and block the movement of the rams, a small shearing pin is so placed in the speed shaft mechanism as to shear before the

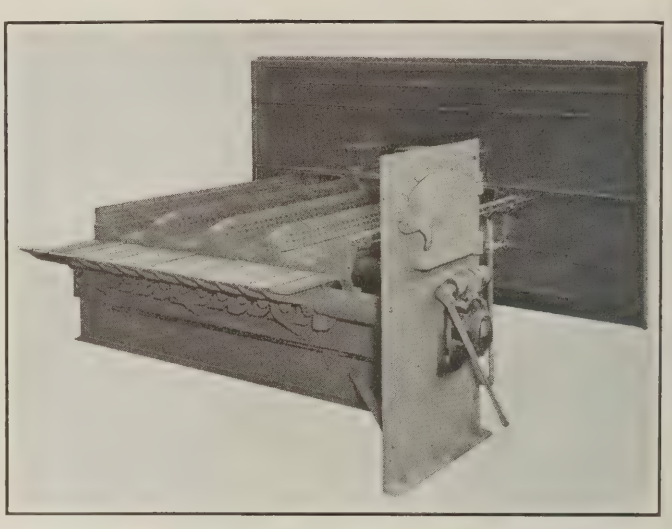
initial stresses are transmitted to the working parts. The Riley and the Taylor stokers also are provided with such a shearing pin.



An auxiliary ram is operated by connecting rods through a lost-motion mechanism which causes it to reciprocate along the bottom of the retort and thus aid in the distribution of the coal. To aid the fuel in its movement to the dumping grates, beyond the retort-tuyere section are reciprocating overfeed grates which actuate through rod and lost-motion connections with the main ram.

Two dumping grates of interchangeable corrugated bars are pivoted upon brackets transverse to the center line of the retort and drop away from each other, thus providing a center dump operated from the side of the stoker. Air is controlled from the front or side of the stoker. Its passage from the wind box to the tuyeres and openings in the overfeed section is controlled by a system of dampers. The tuyeres fit into recesses in the tuyere boxes and interlock each other. The tuyeres are graduated so as to grow smaller progressively from the nose to the sides of the tuyere block.

Natural draft can be used at light loads and with a pressure of 6 or 7 in. in the wind box 400 per cent of rating may be obtained. This stoker is suitable for plants where the load is subject to wide and sudden variations.



In the Taylor stoker, manufactured by the American Engineering Corporation, Philadelphia, Pa., the coal is fed into the retort by a large cylindrical ram which is operated by a crankshaft driven by a worm and gear. It is then redistributed by sets of short-stroke rams connected by links with the main ram. The grate area of a single retort set is composed of a retort inclined at 22 deg., an oscillating overfeed section and a single-leaf dumping grate which is operated by levers located in front of the stoker. The retorts slope steeply and are stepped by V-shaped tuyere blocks.

As an alternative for the hand-operated dumping grate a power dump plate may be used. This is arranged to oscillate rapidly so as to dislodge and dump the refuse and clinkers which might tend to adhere to its surfaces. Yet another provision for disposal of refuse is obtained in the clinker grinder which is sometimes used. It is revolved at a speed slow enough to keep ash above it at all times and thus seal it. Air for combustion is

DETROIT SINGLE RETORT UNDERFEED

This stoker was designed to serve boilers from 100- to 300-hp. For larger ratings two or more retorts are installed in one furnace.

DETROIT MULTIPLE RETORT UNDERFEED

Any number of retorts may be placed side by side, having a horizontal or level fuel bed. A row of tuyeres is placed between each pair of retorts, discharging air into the fuel bed.

forced from the wind box through the tuyeres to the fuel bed and also courses to the oscillating overfeed section. Both are controlled by dampers.

Bituminous and semi-bituminous coal, semi-anthracite and even lignite have been burned satisfactorily with this stoker. A wind-box pressure of 3 to 4 in. with 0.03 in. suction will permit continuous operation at 200 to 300 per cent of rating. From 60 to 80 lb. of coal per square foot per hour can be burned under peak-load conditions.

Different from all the stokers hereinbefore described is the Riley stoker in that the retort wall reciprocates and by direct-connection agitates the overfeed grate bars which extend across the full width of the stoker. The underfeed section is inclined at 20 deg. and receives its reciprocation through side rods driven by wrist pins on the main plunger. The amount of travel is adjusted by setting blocks which regulate the lost motion between wrist pins and side rods.

Air leaves the main air chamber, which is fed by a duct from the blower and travels through the tuyeres to the fuel bed. A damper arrangement regulates the passage of air from the wind box proper to the movable overfeed grate, where its pressure is less near the dump grate than it is near the retort. The dump grate is composed of a number of dump plates that operate continuously. Refuse leaving these plates is further handled by a crusher.

This stoker will burn all grades of bituminous coal and also lignites. A rating of 200 to 300 per cent may be obtained with it.

LEGISLATION TO COMPENSATE FOR DAMAGE BY SUBSIDENCES.—The question of property damage through subsidence due to mining operations has long been a subject of controversy in Wales. Property owners, in offering for sale or leasing land, invariably reserve to themselves the right to work any minerals on the land, and to let down the surface without any compensation to owners of buildings or other erections. One of the Welsh coal-miners' leaders has suggested legislation to compel coal and other mineral operators to compensate property owners and public authorities for damage done to buildings, gas and water mains, sewers and highways through subsidences.

Better Machine Bits Would Lower Cost of Cutting Coal

Power Cost of Cutting by No Means Main Reason for Using Good Bits —Avoiding Burnouts, Reducing Strain, Economizing in Labor, Increasing Service from Machines Are Others—Standardization Needed

By Alphonse F. Brosky
Assistant Editor, *Coal Age*, Pittsburgh, Pa.

WHEN in search of information relative to the "how" and "why" of doing anything much can be learned by talking with the man on the job. So with this belief in mind I chatted with a blacksmith at a mine on the subject of cutter bits for the chain-type mining machines. He was brimful of constructive criticisms of his trade, which, in the main, is the sharpening of bits, and for all his foreign accent and muddling of the English language he was capable of telling an interesting story:

"What's a matter with em bits, you ask me? I tell you what. You hear me what I say. I know someting bout dis job; used to be machine man myself, las' place I work. Some man he sharpen bits good, some man he sharpen bits bad. Good man he get sick, then bad man he sharpen bits and make machinemans sick. Machinemans swear lika hell. No can cut em places that shift. Night boss he mad too since he catch em hell from 'super' in morning. Maybe company call 'super' too; maybe so.

"See this bit, I sharpen em good this way. Wait; I show you 'nother one. Last blacksmith sharpen wrong and edge break off bye-byes. See; too long and not thick 'nough here. Every man got own way; most of time wrong. I know how because I cut em coal one time; see!"

So I spent nearly a half hour listening to the enlightening explanations of this man, at that time engaged in sharpening bits, but formerly on the other side of the fence cutting coal with a chain machine. He knew both sides of the story, and in his own simple way laid emphasis upon features in the shaping of bits. Many of these form the structure of this article.

Go where you will to the larger mines in the bituminous fields, on the days those mines are being worked you are almost certain to notice that bits for chain machines are being sharpened. Depending upon the hardness of the coal or the impurity and the width of the places, after a machine has made a number of cuts—sometimes two and sometimes as many as five—the bits become worn, and, as a result, cannot cut efficiently.

A dull bit in cutting is injurious to the machine itself and reduces the area which the men who operate it can cut in a shift. The blunt steel, instead of tearing into the coal as it should, tends to rub over its surface.

NOTE—The headpiece shows a blacksmith sharpening bits on a mechanical sharpening machine. The heated bit is dropped behind an anvil block which holds it firmly while a roll die passes over it and shapes it. The air for the forge is supplied by a small blower.

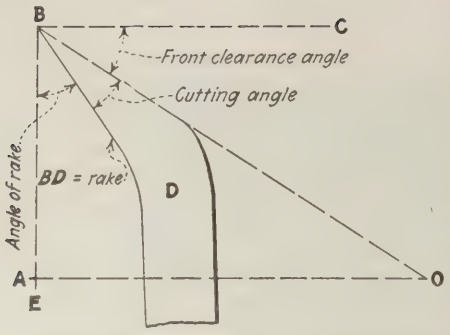


FIG. 1—DESIGNATIONS IN CUTTER BIT DESIGN

In present-day design all the various factors in cutter-bit design are variable. Some standardization would be desirable.

The operative is tempted to load the friction, in consequence of which an overload is placed upon the motor, which will blow its fuses unless the runners have replaced them with copper wire, in which case the armature is likely to burn out. Even if this does not happen an unnecessary strain is exerted on the mechanism of the machine, particularly on the feed chain.

Let it be said here that the runner is tempted to plug the fuse gap with wire of heavy resistance only when his machine is not functioning as it should or when the cutting is difficult. Furthermore, the runner prefers to use an excess of power and injure the coal cutter rather than replace bits, for in his eyes this work is an annoyance and a waste of time. Toward the close of the shift, accordingly he tires of changing bits and is disposed to try to cut an excessive yardage with one setting. Consequently the management should feel under obligation to remove the cause of this evil practice. Supply the runner with well-sharpened bits, and further trouble is likely to disappear.

At most mines bits are sharpened on an anvil or with a power hammer by a blacksmith, who is frequently required to work overtime. He must be skilled in his work; otherwise his bits will not be kept of the desired uniformity. At that, a close scrutiny of the finished hand-sharpened bit will show that no two are exactly alike. When the tip of the bit has been rounded somewhat it can be restored by a few blows of a hammer; but it frequently happens that a portion of the tip is torn off, in which case the steel must be drawn out. This takes time and labor, consequently the blacksmith often is disposed to shirk this part of his work.

But that is not the only objection to sharpening bits by hand. The exactitude with which the bit is shaped is limited by the ability of the blacksmith. The tip may come to a point as in a right pyramid, allowing little or no clearance below the cutting edge. Frequent sharpening of a bit which initially was of the correct shape as to clearance and rake may alter it so as to lower its ability to cut. Choice should be dependent upon efficiency of cutting as well as facility of sharpening.

Ask a machinist who operates a metal-turning lathe as to the theory of shapes applied to his cutting tools, and his remarks will set you to thinking about your own problem. All cutting tools may be considered primarily as wedges driven into the material to separate it. A thin-edged tool cuts more easily because it generates less friction, distorts the chips less and removes them more freely. The edge must be thick enough to make a heavy cut at a suitable speed and have a point of width sufficient to withstand the heat generated by friction. Large roughing tools are round-nosed because that shape provides a longer cutting edge than does a straight-line shape, as notably in a diamond-point or facing tool.

What applies to metal-turning where practices have been developed to a science after years of study and experience should apply also to coal cutting. In the latter case the cutting bits do not overheat, unless a sheet of sulphur or a piece or blackjack is being cut, as the material cut is comparatively soft, and each bit is not constantly cutting coal. Nevertheless, the theory of rough versus fine cutting is equally applicable to either case. We learn from our brother the machinist, therefore, that we must be discreet in our choice of tools for cutting coal.

He could further point out to us, were he to examine our cutting bits and witness our process of undercutting, that may of our bits are poorly designed. They are not provided with the necessary rake, nor do they have the up-and-down clearance which is an extremely important detail of design if friction is to be kept at a minimum.

He has developed his many cutting tools by evolution to the extent that the shop in which he works is equipped with a large number of lathe tools, each of which is meant for some particular job. A specific selection of one tool in preference to another is made only after due consideration of the hardness of the metal, its structure and the rate of cutting, and now he contemplates going a step further by establishing a nation-wide standardization of his tools, which will greatly reduce their number.

He would not expect us to carry our selection of bits to the nicety practiced in his machine shop but he might well wonder why it is that we use the same bit under divers circumstances with little or no regard for the work which it has to be applied. The coal of the many seams mined varies widely in hardness and in structure. Is it not reasonable to suppose, therefore, that judgment should be exercised and a cutting bit of one shape chosen in preference to another for cutting the coal in a given seam? At least should not the tool which is used be of a general design to minimize friction in cutting?

The master mechanic of a large bituminous company hints that managements would do well to see to it that bits are correctly and uniformly sharpened. After wide experience and extensive observation in the problems dealing with correct application of equipment he makes this recommendation—not so much because its fulfilment would effect a worthwhile saving in power as because places would be cut more easily and quickly, so that a single machine would cut more places in one shift and so that the wear and tear on the machine would be diminished, thus reducing maintenance cost by minimizing the frequence of repairs. To convince himself that the power cost in the cutting of coal by machine is a negligible consideration the master mechanic men-

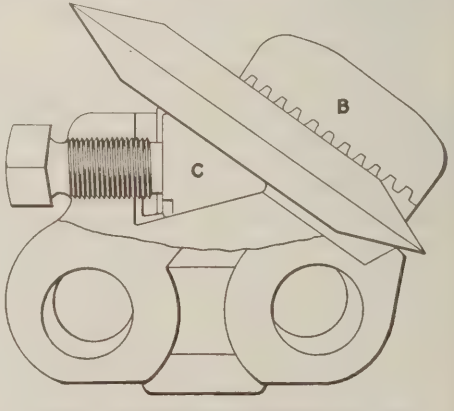

FIG. 2—SELF-SHARPENING BIT

Bit can be turned side for side and end for end, thus affording four sharp cutting edges before it needs sharpening. It cannot work loose.

tioned made a number of electrical tests of power consumption under different conditions. Most important of his discoveries was that the power consumption per square foot of undercut was not so high as to impose an important burden on the costs of operation. Depending upon the coal cut and the type of machine used, the power consumption varied from 22 to 56 watt-hours per square foot. A summary analysis of a particular machine, a Goodman universal shortwall mining machine, shows that it cut an average of ten places per shift. The length of the cutter bar and the width of the room cut were 7 and 17 ft. respectively; the power consumption per square foot of undercut was 23 watt-hours, and 4 kw.-hr. was the average power consumed per place cut, including moving from room to room.

Figuring the cost of cutting (at night) at 1.5c. per kilowatt.-hour, the cost of power to cut ten places was 60c. The power cost for one machine, even where the cutting is difficult, seldom exceeds $1 per shift. At that rate the power cost for undercutting 2,000 tons of coal varies from $6 to $10 and constitutes about one five-hundredth of the prime cost of producing the coal. For this reason we may regard power cost as an unimportant factor as compared with the direct cost of mining.

This point is emphasized in order to set aright those who judge the worth of an improvement in coal-cutting machinery solely by its saving in power. Though a reduction in power consumption is an indication of improvement, we are more concerned with ease and speed of cutting than with power consumption. Cause each machine to cut one additional place, and nine machines will do the work of ten. Reduce power consumption one-half and the saving of itself is small. Cut more places per shift and provide that delays and repairs occur less frequently, then something will have been accomplished. On this fact depends the plea that uniform and correctly shaped bits be used in the cutting of coal.

Though the two general types of bits in wide use are the chisel point and the pick point, their shapes are many, each arising from the individual ideas of the maker. How foolish it would be to use promiscuously any one of the shapes under any one given condition! Of the two types the pick point is that most used. Its shape varies from a needle-like point with squared corners to a round nose having a flat rake and a rounded drag. This last shape can be correctly formed only in the dies of a bit-sharpening machine.

Less power is required to operate pick points, which means that cutting is easier; but in a hard substance, such as sulphur sheets, chisel points are more applicable, because they protect the links and setscrews of the cutter chain from being abraded by the substance they cut. This last objection, however, is ruled out where cutter chains of seven or nine positions are used. In addition to these, several freakish shapes have been tried; some are curved in a prong point; in others the effective cutting edge is turned askew relative to the center line of the bit.

Would it not be well to standardize bits and reduce the number from one hundred or more to a half dozen well-defined shapes? Each shape could be numbered to indicate its adaptability to a coal of a given hardness. Thus No. 1 bit would be suited to very hard coal. No. 6 bit to very soft coal and the intervening numbers to graduated degrees of hardness. This, of course, would lead to the standardization of cutter chains also

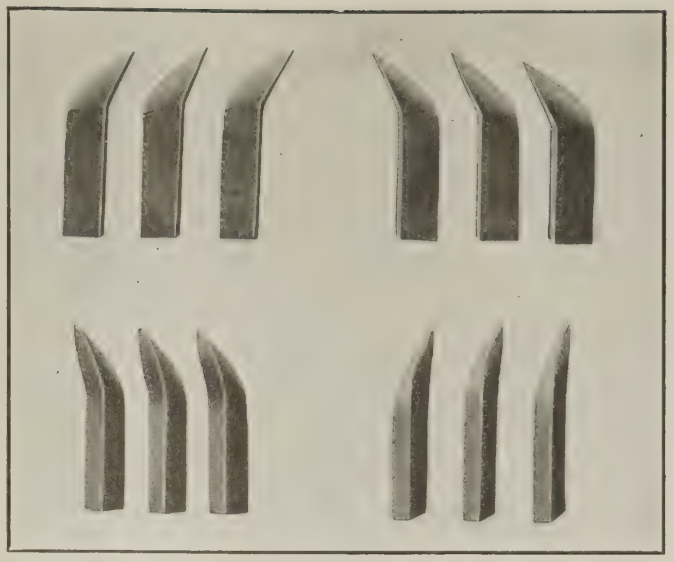

FIG. 3—PICK POINTS FOR CUTTING MACHINE
The pick point is suitable for coal that is easy to cut. It can do the work without becoming unduly heated with injury to the point.

—there is no reason why a standard cutter chain should not be applied to all cutting machines regardless of make.

These shapes could be derived through empirical tests, and the seams of coal being mined in this country could be grouped under six numbers according to their degrees of hardness. No longer would the mechanical man at the mines be in the dark as regards the shape of bit best suited to this needs nor would he experience trouble in making or having the bit made, knowing the shape best suited to his purpose.

There are relations between the angles and dimensions of a bit which affect its efficiency in cutting. Most of these are known by the makers of cutting machines and the rest could be worked out. Thus the smaller the cutting angle (see Fig. 1), the longer is the rake. Sometimes the cutting angle is referred to as angle AOB. In reality it is not, for the angle AOB is equal to the angle OBC, which is the front-clearance angle. To machinists the cutting angle is the angle OBD.

The harder the coal the smaller should be the front-clearance angle, and the softer the coal the smaller should be the cutting angle. The side-clearance angle has practically no relation to the other angles, the dimensions of the bits or the hardness of the coal to be cut. It could be made a constant for bits of all shapes.

How to obtain and maintain at the mine a uniformity in the shape of the bits is not an obstacle. Many intricate forgings are made by machines in other industries, and consequently there is no reason why machine dies could not be designed to make a bit of any shape found desirable.

The carbon content of the steels to be used in making these different shapes of bits could be specified. At the same time methods of tempering each steel could be evolved. Much of the trouble with bits is due to faulty tempering of the steel.

Of the many bits now in use only two might be recognized as standard. The term "standard" as applied to bits in this instance is meant to connote correct shape, which may be maintained uniformly in sharpening rather than universality of use. In this category are the Link-Belt double pointed bits, which owe their efficiency in cutting to the devices of the cutter chain

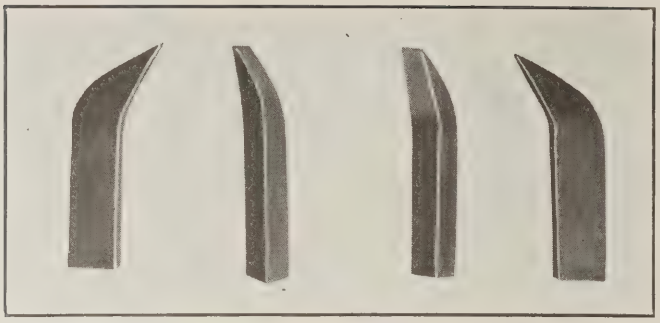

FIG. 4—CHISEL POINTS FOR HARD CUTTING

The chisel point is used where sulphur sheets are encountered. It lasts longer than the pick point, given similar material to cut. It can, however, be dispensed with where cutter chains of seven or nine positions are used.

which holds them, and the Sullivan machine-sharpened bits, which cut successfully because all are sharpened exactly alike in a machine die.

Both ends of the Link-Belt bit are symmetrically pointed. For this reason when the cutting edge of one point is worn, maintaining the same point uppermost and turning it side for side, a fresh cutting edge is put into position for cutting. After that edge is dulled the bit is turned end for end, giving it two additional cutting edges. The designs of the bit and the lug link which grips the bit are shown in Fig. 2.

The bit is gripped in the cast-steel lug link by two bearing surfaces. One of the grips, B, is corrugated and fixed as part of the lug link while the other is a movable wedge, C, which is positioned by a setscrew. The wedge and corrugated grips act in a manner to tighten rather than loosen in cutting. Consequently all bits are held in line as set, and none is lost in the cutting of the coal. Because the cutting angle (term used in the sense of angular position) is obtained by the position of the bit in the lug link, the efficiency of cutting does not depend so much upon the skill of the blacksmith in shaping it as it does with other bits. In the Link-Belt cutter chain the lug grips maintain this cutting angle, which, therefore, is mechanically controlled.

For details regarding the Sullivan bit sharpener the reader is referred to pp. 826, 827 and 828 of *Coal Age*, May 18, 1922. Briefly this machine is a belt-driven, oscillating roll die which draws out the point of each bit sharpened to exactly the same shape. An examination of the headpiece to this article will reveal its working principles. The finished bits are shown in Figs. 3 and 4.

About eighteen months ago a mechanical bit sharpener was installed at a mine which produces 2,000 tons of coal daily. Prior to this time the blacksmith shaped the bits on an anvil and sometimes had to work overtime in order to put a fresh edge on all the bits needed for the next day's run. One set of bits such as he could make by hand would cut no more than three places, whereas a set of the machine-sharpened bits now used will cut from seven to nine places. Repair costs have been lowered as a result.

Surges of current through the motor of a mining machine caused by variations in the load burn out many armature coils. In fact the armature coil in a mining machine is replaced more frequently than any other part. When hand-sharpened bits were used four of five coils burned out each week, but now the number is reduced to one.

Coal-cutting machines have been and constantly are being improved so that today they are both efficient and reliable, but a similar advance cannot be noted in the implement that actually performs the cutting, namely the cutter bit. We see much evidence of inefficiency caused by its shortcomings in general; on the other hand we have some evidence of its efficiency when due regard for correct design is observed. This problem concerns every soft-coal operator and consequently should receive more study.

Anthracite Small Sizes as Competitor of Bituminous Coal for Locomotive Use

Anthracite is consumed by railroads to some extent, the Lackawanna advertising its use in locomotives as a feature not to be overlooked by the traveler who decries dirt and sulphurous smoke. In recent years it is the smaller sizes rather than the much more valuable household coal that gets into locomotive fireboxes. In the April issue of *Baldwin Locomotives*, published by that famous Philadelphia maker of locomotives, is an article on the Philadelphia & Reading R.R. in which are some very interesting figures on the use of small sizes of hard coal in competition with bituminous coal in road service on that road's locomotives.

The figures given below are those showing the relative percentage of each used in several types of service, fast and slow:

NEW YORK DIVISION

Through passenger service	*Winter*	50 per cent buckwheat, anthracite 50 per cent bituminous
	Summer	60 per cent buckwheat 40 per cent bituminous
Local passenger service	*Winter*	60 per cent buckwheat 40 per cent bituminous
	Summer	70 per cent buckwheat 30 per cent bituminous

READING DIVISION

Through passenger service		Same as New York division
Local passenger service	*Winter*	65 per cent buckwheat 35 per cent bituminous
	Summer	75 per cent buckwheat 25 per cent bituminous

HARRISBURG DIVISION

Through passenger service		Same as New York division
Local passenger service	*Winter*	75 per cent buckwheat 25 per cent bituminous
	Summer	80 per cent buckwheat 20 per cent bituminous

A more striking instance of the efficiency of steam sizes of anthracite would be hard to cite. The record of the Reading for operating its trains at high speed, and getting them in on time need hardly be mentioned. The article in *Baldwin Locomotives* adds:

"The selection of these mixtures has been made an object of special study, with a view to combining high efficiency in operation with a minimum charge for fuel."

If the Reading, by mixing buckwheat with bituminous, gets high efficiency at the lowest cost, it would seem logical to suppose that other fuel users, especially those in anthracite territory, could duplicate that experience.

MINERS SAY THERE WILL BE NO SOFT-COAL STRIKE in 1923, so now we can put all our worry on the hard coal.—*Denver Express.*

Mortar Ejected from Cement Gun Protects Roof from Injurious Effects of Mine Atmosphere

Believing That Gunite Had Now Been in Place Long Enough to Reveal Its Qualities, "Coal Age" Requested a Representative to Inquire as to Its Ability to Prevent Roof Falls in Roadways

GUNITE is a mixture of cement and sand with water, projected as a plaster under pressure by a special device for that purpose, known as the cement gun. In the early days of its introduction, a little more than ten years ago, little confidence was shown around the mines in the permanency and value of such thin sheets of cement mortar, though it was recognized that the mixture thus sprayed was much denser than any hand-troweled coating. Its importance today in not only one but in all the heavy industries is justly recognized.

The civil engineer recommends its use in the facing of dams, reservoirs, spillways and ditches because of the ease with which it may be applied, its imperviousness to water and its great strength when reinforced with steel; the chemist recommends its use to protect materials such as metals from the attack of corrosive liquids and gases, and the metallurgist and combustion engineer each has borrowed the principle of applying gunite, in the one case for lining crucibles, retorts, blast, open-hearth and reverberatory furnaces with high-temperature cements and in the other for the repairing of boiler settings.

In the mining industry gunite is saving large sums of money chiefly by holding the roof of entries but also by facilitating construction work in or about the mines. Mining in sedimentary rock formations such as coal and the superincumbent measures has ever been dangerous and uncertain, and consequently any means that will decrease its inherent dangers and reduce the costs of maintaining excavations is of the greatest importance to the coal industry.

Its first accomplishments in coal mines were inspected publicly in 1916 when a group of prominent mining men visited the experimental mine of the U. S. Bureau of Mines at Bruceton, Pa. In this mine gunite had been placed on the surface of about 300 lineal feet of entry at the extreme inner end of an explosion chamber where the causes and effects of coal-dust explosions were being studied. Prior to the visit of this group of men it is estimated that nearly three hundred blasts were exploded in this chamber in the presence of finely comminuted coal. Some of these were of such violence as to crack the concrete lining which had been placed on the first few hundred feet of the entry.

Between the stretches of gunite and concrete was an interval of perhaps 400 ft. where no lining had been placed. Examination of this section revealed that the drawslate above the bibs of coal had been cut to such a degree that the span had been widened and the roof thus weakened. The rock over the roadway had fallen in places to considerable heights. The gunited portions evidenced no signs of slacking except where the coating was less than ½ in. thick. Timber sets, if placed in this entry to hold the roof, would have been dislodged by the first explosion following their erection.

The possibilities of the method were readily apparent. Here was a means of preventing a deterioration of the roof such as is the cause of most falls. Moreover, it would make the roof and ribs proof against fire. It is well known that coal will be ignited by the heat of a short-circuit such as frequently is caused by the grounding of a trolley wire.

They could see that the elimination of timbers along the main entries would make the roadways safer for derailments frequently dislodge timber; that men could travel back and forth with reasonable assurance of protection from roof falls, and that much expense would be saved by reason of the decreased necessity of removing fallen rock from haulageways. It also would make the haulage safer, for derailments are always to be feared where rock falls on the tracks.

This same group of men visited the Mt. Pleasant mine of the H. C. Frick Coke Co., which was one of the first commercial mines in which the roof of an entry was gunited for the purpose of preventing falls of rock. For a distance of 150 ft. adjoining an 18-in. brick arch near the shaft bottom a ⅛-in. coating of gunite had been applied. Though the thickness was less than the ½ in. recommended, there was no indication that at any point had the gunite broken off or the roof slacked.

From that mine the party went to Irwin to inspect Edna No. 1 mine of the United Coal Corporation. On the day of the visit a fall on the slope of the main haulageway had closed down the mine. This was the most troublesome slope in the region. The bad roof which is so general near the outcrop of the Irwin Basin had been further weakened by the ill-advised methods by which the mine had been operated in its early development, over twenty years earlier. The coal had been extracted on both sides of the slope with little consideration of the needs of the future, the barrier pillars, if

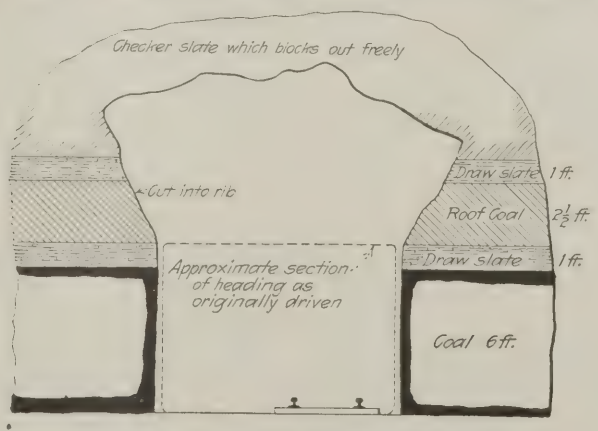

FIG. 1—CROSS-SECTION, SLOPE AT EDNA NO. 1

This slope, located on the edge of the Irwin Basin, kept disintegrating and falling until it reached a height of 12 ft. The coal ribs also spalled and widened till the roadway was 12 ft. wide. It was gunited six years ago and falls are now infrequent. Three trackwalkers used to be employed, and the condition of the slope made the flow of coal irregular. Only one man now is needed, as falls hardly ever occur.

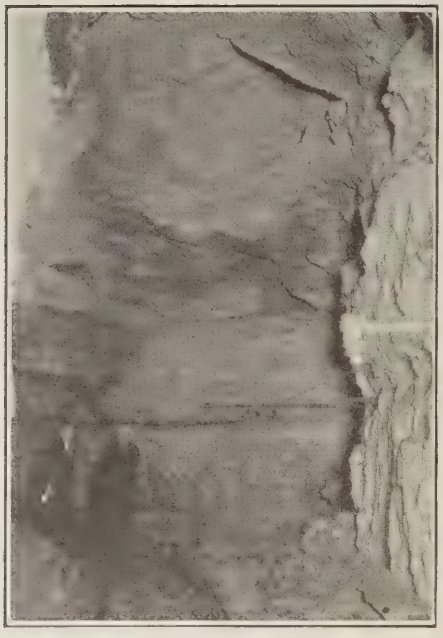

FIG. 2—HIGH PLACE, PITTSBURGH SEAM

The roof is 20 ft. above the rail as the result of continued caving. It has been gunited to render it safe and to make it economical to haul coal beneath it. A rotten sandstone lies above the coal.

FIG. 3—ENTRY ROOF CUT BY MINE AIR

The sweating of warm, moist, intake air makes the roof wet and subjects it to a weathering process. The changes in temperature also weaken the roof by expansion and contraction.

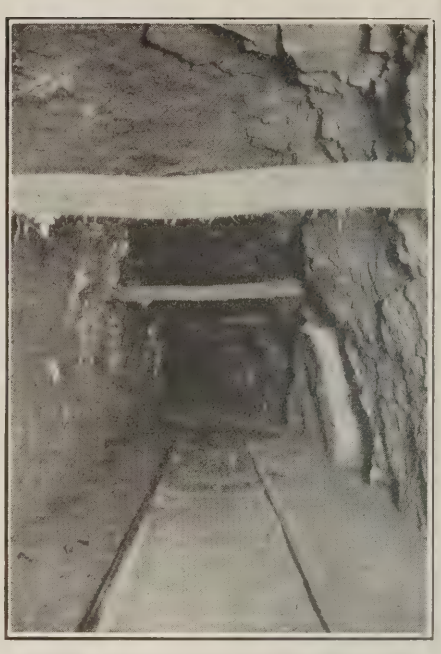

FIG. 4—ROOF SHOWN IN FIG. 3 GUNITED

Both Figs. 3 and 4 show conditions in the Gibson mine of the Hillman Coal & Coke Co. Because this section was wet, it was expected that it would have to be timbered, but the result was as shown.

such they could be termed, left for the support of the roadway being in places inordinately narrow and inadequate for the purpose intended.

The slope is one mile long and consists of a haulageway, a manway and two airways driven 10 ft. wide on 50-ft. centers. It is protected by barrier pillars which vary in width from 100 to 200 ft. Falls along this slope caused the mine to be shut down two to five days each month. The slope was timbered heavily and could be kept open only at great expense. Above the 6 ft. of Pittsburgh coal is a roof of drawslate 12 in. thick. Above that is approximately 30 in. of roof coal separated from a thick checker slate by another 12-in. stratum of draw slate. This uncertain material is overlaid by a solid sandstone.

Soon after this trip of inspection Edna No. 1 mine was acquired by the Hillman Coal & Coke Co., and the timbers lining the slope were removed, the roof and ribs being trimmed of all loose material. Gunite was then applied to a thickness of ¾ in. on roof and ribs. Though these entries originally had been driven 10 ft. wide on 50-ft. centers the roof and ribs had deteriorated to such an extent that in computing the cost of the gunite work, the height and width of the entries were each calculated to average 12 ft., the aggregate totalling 36 ft. Fig. 1 illustrates a typical cross-section of the haulageway.

At B Flat, 2,500 ft. from the slope mouth, a concrete wall several hundred feet long had been erected on either side of the track and walkway to support the roof where it had been brushed for the purpose of adjusting the grade over a local dip, this brushing having caused a considerable increase in the span of the roof.

The worst condition in the slope is found at 3 Flat, 100 ft. in, where the barrier pillar is only 55 ft. wide. In places rooms were driven through to the slope entries so that the ribs afford little protection to the roadway.

A short time ago the writer inspected this slope and found that the gunite had done much to hold this roof in check. The original gunite applied six years ago was still intact in places though it had been patched in spots of small, and sometimes exceedingly large, areas where the roof was heavy and fell. A comparison of the number of falls before and after the placing of gunite is indeed striking.

Prior to the completion of this work as many as three falls occurred daily. Three men were employed as slope walkers, whose duty it was to watch for signs of impending falls, which, when they occurred, inevitably crippled the haulage and decreased production. Today only one slope walker is employed, and he has a sinecure, for last summer in a period of three weeks only one fall occurred. The cost of placing the ¾-in. coating of gunite along this slope was $1.25 per lineal foot, which was 3½c. per square foot.

A consulting mining engineer reports that he witnessed the driving of a slope 400 ft. long through alternate strata of sandstone, shale and clay overlying the Lower Kittanning seam. When first driven the top and sides seemed so hard that it was considered unnecessary to timber the slope except for a short distance near its mouth.

As time went on, however, small pieces of the clay and shale kept falling until the slope became in places both high and wide. Gunite was applied to the top and sides, and though six years have elapsed since the completion of this work there has been no further trouble with the roof except in a small area where a large quantity of water at one time escaped into the roadway and made it difficult to obtain the requisite adhesion of the gunite to the rock.

An account of the guniting of entries in the mine of the Allegheny River Mining Co., Kittanning, Pa., appeared in *Coal Age* Aug. 14, 1919. A few words at this time regarding the permanence of this work will be scarcely out of place, as this company was one of the first to adopt the guniting of its haulageways as a standard practice. A report of its experiences prior to 1919 is reproduced on the next page:

"Along 5,842 lineal feet of headings covered with gunite not a single fall of any consequence has occurred either from the roof or the sides. This is certainly remarkable in view of the contrasting conditions which formerly existed when thousands of dollars were spent each year to clean up falls, to repair dislodged trolley wire, and to rectify other conditions consequent on the weakness of the roof. Timbering to support the entries cost at the rate of $7 per lineal foot, which is a prohibitive figure as compared with the expenditure of 75c. per lineal foot which is all that it has cost to support the roof with gunite."

In a recent statement this company reports that about two miles of entry has been gunited with entirely satisfactory results. The oldest gunite, which was applied five years ago, is holding well, though it must be patched periodically where thin sections have spalled. The average thickness of the coating is estimated to be ⅝ in.

Entries in both the Upper Freeport and the Lower Kittanning seams have been covered with equally satisfactory results. The roofs over these seams disintegrate rapidly, and small pieces drop from them so readily that the entries widen as the roof rises higher and higher. Timbering will not remedy such a condition. Gunite has kept the cross-section of the entries uniform over a period of years. The management specifically attributes its success in holding the sides and roof to an occasional patching of all areas where spalling occurred.

In No. 2 mine of the National Mining Co., near Pittsburgh, Pa., a shaft was sunk to handle the large quantity of slate that falls in the roadways. During the mine workers' strike in a distance of only 1,500 ft. about 1,500 tons of rock accumulated on the "Parallel Entry" leading from this shaft. In the first days following the settlement of that issue approximately 3,700 tons of rock was hoisted up the slate shaft. The weight of this slate was 30 per cent as large as that of the maximum production of coal which could have been hoisted in that period. This "Parallel Entry" was gunited, roof and ribs, immediately following the clean-up, and to all appearances this work has permanently checked further falls from the roof.

Before gunite was applied the top fell so freely that there was a constant fear that some one would be killed or injured from this cause. Two wiremen were employed to traverse the haulageways, totaling one mile in length. They were kept busy replacing the trolley brackets and rods which were continually coming down. In four years' time following the driving of this entry the roof scaled off to an average height of 15 ft. Above the 5½-ft. seam of Pittsburgh coal is an 8-in. band of draw-slate and then roof coal split by two bands of slate and a sheet of pyrite. A "rotten" sandstone 6 to 8 ft. thick is encountered above the roof coal. To make matters worse, coal and other soft strata are found above this fragile layer of sandstone.

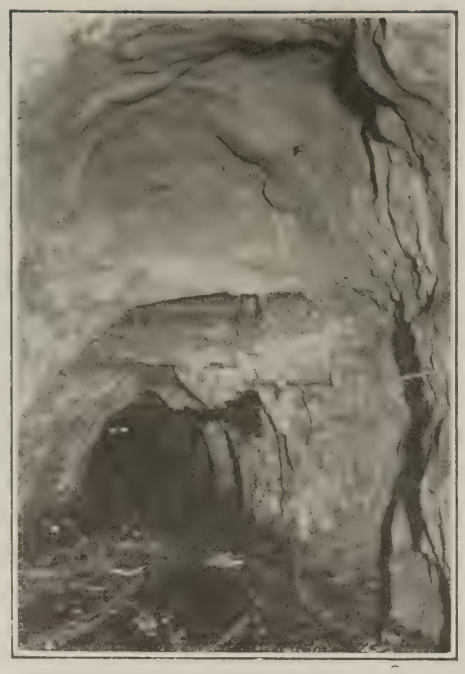

FIG. 6—GUNITE IN WET PLACE

Wolf Summit Mine. Roof falls to the greatest height where the water is most profuse*.

Needless to say, this sandstone could not be prevented from falling after it had been exposed to the air. It broke to considerable heights, as is made obvious by an inspection of Fig. 2, which shows a high place on the empty haulageway. Here a pot has been formed in the sandstone of a depth equal to the thickness of this rock.

The turnout in Fig. 5 widens out from a span of 11 ft. to one of 24 ft. and illustrates a natural condition in a representative mine. Heavy steel beams placed across this span of roof, when properly lagged and propped, would hold this roof temporarily, but the inadvisability of thus supporting it is readily apparent.

To begin with, steel beams would be quite expensive, and, though for a while they would give absolute security, air inevitably would leak through the lagging and loosen the roof material, which would settle upon the beams. In time the load would become so great that it would buckle the steel unless it was taken down occasionally and the load removed.

Conditions in the mine of the Wolf Summit Coal Co., near Clarksburg, W. Va., are different from those already described. The 8-ft. Pittsburgh seam is very friable and acts somewhat in the manner of a checker shale, so that timbering will not hold it in place along the entries, even where 2 ft. of the coal is left in the roof. The coal thus left is of equal quality with that extracted and one naturally is led to wonder why all the coal is not taken out at the same time and gunite almost immediately applied.

The answer is that a smooth slate, resembling a soapstone, and which weathers freely, lies directly above the seam, and if all the coal is taken out the roof begins to fall immediately, pieces weighing as much as 6 tons detaching themselves from the roof a few days after the

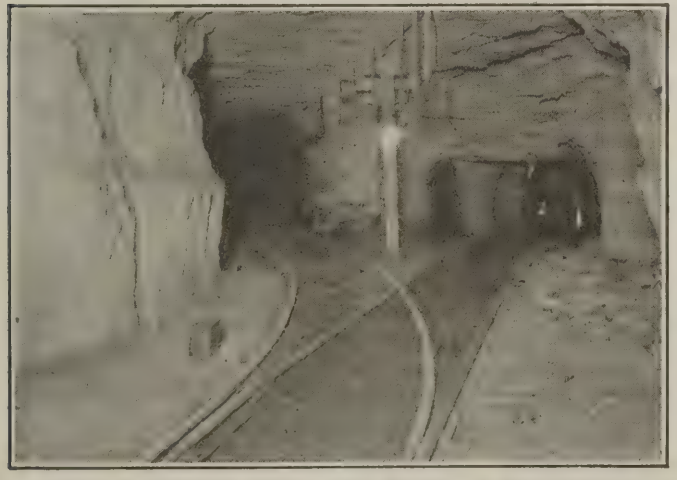

FIG. 5—GUNITE REPLACES STEEL AT TURNOUT

Scene in workings of National Mining Co. Though the span is 24 ft. at the point of the center pillar the roof is holding well as is evidenced by its flatness. Ribs as well as roof are gunited.

*Even in wet places with patience and skill gunite can be placed and will stay. In Fig. 6 may be seen the seep pipes inserted in the roof. After the pipes and the necessary rods were placed the gunite was worked inward toward them. The exposed coal on the right rib was trimmed to line up the trolley wire and is not the outcome of spalling.

FIG. 7—UNTRIMMED ENTRY IN WOLF SUMMIT MINE

The roof appears to be neatly corbeled from the ribs outward, but unless the overhanging material, which happens in this case to be coal, is trimmed from the roof and rib to the left, the gunite will crack after application. The left rib should be trimmed to look like the right rib.

coal is mined. If the gunite is applied to this slate as far away as 80 ft. from the face, the shock of a blast in the coal will dislodge the green gunite.

Yet despite the unusual difficulties, a few of which already have been explained, gunite is applied to the roof and the sides of the headings. Coal left in the roof in the driving of headings soon begins to break loose, the coal corbeling out over the roadway along each rib (see Fig. 7). This has to be trimmed before gunite can be applied. It is difficult to know whether any given portion of the entry has been properly trimmed, for it is impossible to judge just how much of the overhanging coal has been strained and its cohesion destroyed. Then also in some places large quantities of water are encountered (see Fig. 6). Under such circumstances the cement-gun crew has trouble in making the gunite stick.

In spite of the adverse conditions and in face of a bad sweating season last summer, during which time the mine was shut down by the strike, the roof was held by the gunite, so that after a year's idleness the mine resumed operation without a single fall having to be removed. The company believes that if the entries had been timbered it would have had to clean up all the headings. It bases its belief upon the experiences in a neighboring mine which is timbered and not gunited and from which large quantities of rock were removed before a resumption of mining.

The slacking or cutting of the sides and roof on fresh-air entries is most pronounced during the warm months of the year when the humidity in the air is condensed by the cool roof and ribs. Similarly, but in an even greater degree where mines are humidified with steam during the winter months, the roof if weak will slack and even fall in large masses. The Winding Gulf Colliery Co., of Winding Gulf, W. Va., met with such an experience and decided to apply gunite to the ribs and roof. Though this work was completed five years ago, the coating in the main is sound, requiring patching only occasionally at points where portions have fallen.

The material above the coal in most workings is not so weak as in the Wolf Summit mine and has strength enough to support itself when the roadway is driven, but the variation in temperatures of the ventilating air sets up stresses in the outer surfaces of the roof and ribs. Often the intake is so cold as to freeze the water which the roof contains. Moisture also is deposited on the cold surfaces during the sweating seasons and certain constituents in the rock oxidize.

Most of the moisture is deposited on the intake airways so that when the air reaches the return it is less humid and its temperature is more nearly that of the roof and ribs. Consequently falls on the return airways are less severe than on the intakes. It would seem advisable to exclude the air and moisture from the top and sides of entries. This may be accomplished by the use of gunite. Under most circumstances it will perform the duty assigned to it much more effectively than timbering and at a much smaller initial cost. Though easily applied it possesses the merits of being more permanent than timber and maintainable with less labor.

To say that gunite is a panacea for bad roof under all conditions would be an overstatement of its value. In making recommendations to one of his friends regarding the cement gun an operator intimated that there was no doubt that gunite will hold the roof in a mine where falls are caused by a deterioration in the roof due to the action of the atmosphere and not by inherent weakness in the roof, rock strains due to mining or gas pressure. This leads to an important consideration.

The Pittsburgh and the Freeport seams in the Pittsburgh region are known to be topped over limited areas with unusually bad roof, under which steel timbering will buckle and give because of the enormous loads which it must carry. Occasionally in driving into new territory gas pockets above the headings burst intervening rock and cause huge falls. Roof in stretches of 1,000 ft. or more are known to come down over night in an almost continuous line, the breakage extending several feet above the coal. This happened only recently in a mine working the Lower Kittanning seam. In such rare instances the logical solution is to let the roof come down, for usually it will fall to a certain height and then stop, after which gunite may be used to check further deterioration.

On haulageways, above all places, men come and go

FIG. 8—TOO THIN A COATING OF GUNITE

A glance at this illustration will convince anyone that the gunite coating of these ribs is too light. The roof and ribs retain the rough and jagged appearance of the original surface, which would not be the case if the gunite has been used less sparingly. With a better coat the cavities would have been filled and the entire surface rounded.

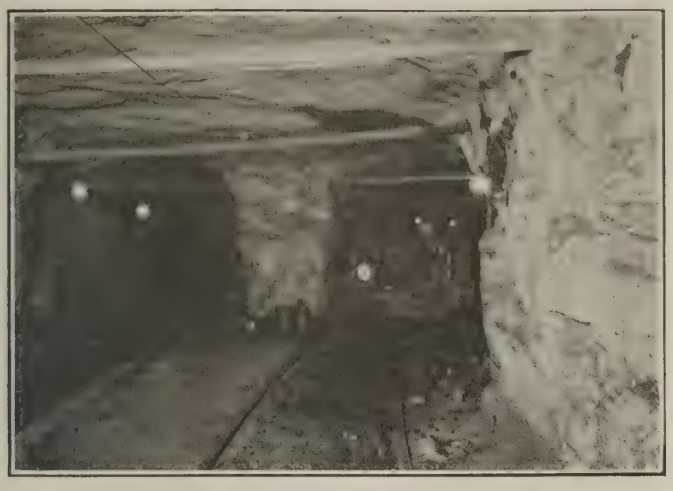

FIG. 9—SPALLED AREA NEEDS PROMPT PATCHING

Directly above the mine locomotive a large spalled area can be detected in the roof. The air has worked its way behind the gunited material through the exposed edges and caused the development of a large crack above the foremost trolley beam. The ribs also are beginning to spall, the coating being too thin. Where ¾ to ⅞ in. coat is used no trouble is experienced. Pressure of gas had caused many falls in the roadways before the gunite was introduced.

so often that protection against falls should be provided where the roof is known to be weak and treacherous, but if steel sets are used as supports and it is found that they sag under the roof they are intended to hold, they should not be employed except perhaps at shaft landings and turnouts. Would it not be better to support bad stretches of roof elsewhere by wood timber sets instead of steel, relying on them until it is clear that the load is becoming excessive? They then could be pulled down and the loose rock be allowed to fall, and other rock that is relatively loose could be barred down. Gunite then could be applied with some assurance that the difficulty thus met would not recur. In most cases the use of gunite in the first instance would make timbering entirely unnecessary.

Coal Mining Shown to Be Safe Occupation

UNDERGROUND coal-mining is safer than window cleaning, carpentry, running farm machinery, house painting and more than one hundred other occupations, according to figures made public May 9 by the Bituminous Operators' Special Committee, of which J. C. Brydon, of Somerset, Pa., is chairman. To determine the danger in coal-mining compared to that of other occupations generally considered less hazardous, Mr. Brydon pointed out, the State of Indiana was chosen as the most representative. The National Council of Workmen's Compensation Insurance fixes the rate at $3.55 which an employer of underground coal-mine labor in Indiana must pay per $100 for his payroll.

Compensation rates for underground miners in the different states, Mr. Brydon explained, vary from $2.50 per $100 payroll in Virginia to $5.60 in Illinois, while in more than two-thirds of the states the rate is between $3 and $4. Indiana, with a rate of $3.55 per $100 payroll, approximates the average for this type of insurance in all coal mining states.

"Merry-go-round and roller coaster employees," Mr. Brydon said, "are considered by Indiana insurance men as more liable to injury or death than underground coal miners, as shown by the rate of $5.85 per $100 payroll as against the mining rate of $3.55. Mining in nearly every other form, quarrying and excavating are considered more dangerous than coal-mining, the figures show.

Besides being a comparatively safe occupation, Mr. Brydon stated, underground coal-mining is carried on under more pleasant working conditions than occupations calling for higher insurance rates and less pay to the worker. In most Indiana mines the temperature winter and summer remains virtually the same; in one mine, for example, the temperature remaining within one point of 69 deg. the year round.

Although there are at least 100 occupations in Indiana, which is fairly representative of the United States, classed as more dangerous than coal mining, Mr. Brydon asserted that few if any of workers in these extra-hazardous callings receive a day-labor wage even approaching $7.50 a day, the minimum received by the underground day laborer in unionized fields.

The relative risk of each occupation may be estimated by comparing its insurance rate with $3.55, the Indiana underground coal-mining rate. The list, in part, follows:

Occupation	Base Rate per $100 Payroll
Cattle dealers	$3.57
Veterinary hospital employees	3.57
Drilling or dismantling oil wells	3.58
Bottling	3.61
Wood preserving	3.84
Drop or machine forging	3.84
Manufacturing chains, tools or hardware	3.84
Manufacturing shoddy	3.88
Erection of mausoleums or monuments	3.88
Painting signs on buildings	3.90
Erecting awnings and tents	3.90
Hanging flags and bunting for conventions and celebrations	3.90
Erecting advertising signs	3.90
Manufacturing carbonic-acid gas	3.98
Construction of electric light and power lines	4.01
Installation and repair of boilers	4.36
Manufacturing veneer	4.37
Scaling boilers	4.42
Erection and repair of elevators	4.65
Cotton ginning and compressing	4.77
Operation of electric light and power plants	4.89
Manufacturing cotton wadding and waste	4.91
Garbage reduction or incineration	5.31
Employees of horse sales stables	5.79
Ice harvesting and storing	5.84
Employees on merry-go rounds, roller coasters, etc.	5.85
Manufacturing cottonseed oil	6.21
Cleaning outside of buildings	6.27
Pile driving for foundations	6.52
Raising or moving buildings	7.41
Junk dealers, in shops or outside	7.99
Erecting blast furnaces	8.21
Metal stamping	8.24
Wrecking buildings or salvaging after fire	9.64
Window cleaning	12.09
Workers on rigging, not on vessels	14.91
Erecting scaffolds	16.10
Erecting iron and steel structures	16.10
Painting steel frames and bridges	16.10

Output of Coal on Public Lands in 1922 Double That of Previous Year

Production of coal upon public lands during 1922 more than doubled the output of 1921, according to figures recently issued by the Department of the Interior.

The number of mines that were operated upon public lands totaled 101 in eight Western states. Of these states the largest number of operations were in Wyoming and Colorado, each having twenty-eight mines. Wyoming, with an output of 390,000 tons, produced more than one-half of the total amount of coal from government lands. Colorado, with 165,000 tons, ranked second; North Dakota, with 67,000 tons, was third, and Utah, with 61,000 tons, was fourth.

Production of coal from government lands, by states, for the years 1921 and 1922, was as follows:

States	Mines Producing in 1922	Tons of Coal Produced 1921	1922
Colorado	28	13,096	161,546
Montana	20	3,533	5,454
New Mexico	4	2,816	14,009
North Dakota	8	27,710	66,924
South Dakota	2	.....	424
Utah	9	9,622	60,809
Washington	2	5,175	49,243
Wyoming	28	300,221	390,763
	101	362,173	752,172

Cambria Steel Co. Finds That Good Housing Increases Output*

By George Atwell Richardson
Cambria Steel Co., Philadelphia, Pa.

Well-Planned Residences with Modern Comforts in Village of Slickville Lower Turnover and Promote Contentment—Plans of Houses Already Constructed—Sewage Disposal—Many Houses Have Bathrooms, Running Water and Toilets

NO MAN is thoroughly contented unless he has a pleasant and happy home life, and the frame of mind of his wife, if he is married, is an important factor in attaining this condition. It is difficult to remain cheerful and good-natured if one's life partner is always nagging and complaining.

The average woman is not naturally ill-tempered. As a rule some extraneous cause is at the bottom of the difficulty, and no more fertile reason can be found than that of indifferent or bad housing accommodations. Give a woman a good home, and the foundation, at least, of her happiness has been laid.

Two of the main sources of difficulty in maintaining satisfactory outputs at any mining operation are: (1) The miner who drifts from place to place, the man who has no home ties to bind him and who is up and away at the least provocation; (2) the discontented miner who not only fails to measure up to his own best abilities but is a cause of dissatisfaction and contention among his fellow workers.

When the Cambria Steel Co. started to develop a new mining operation at a place about fifteen miles north of Greensburg, Pa., on the Turtle Creek Branch of the Pennsylvania R.R., it recognized these conditions and all plans were based on providing, first of all, really good housing conditions for its workers, a policy which has been fully justified by the results.

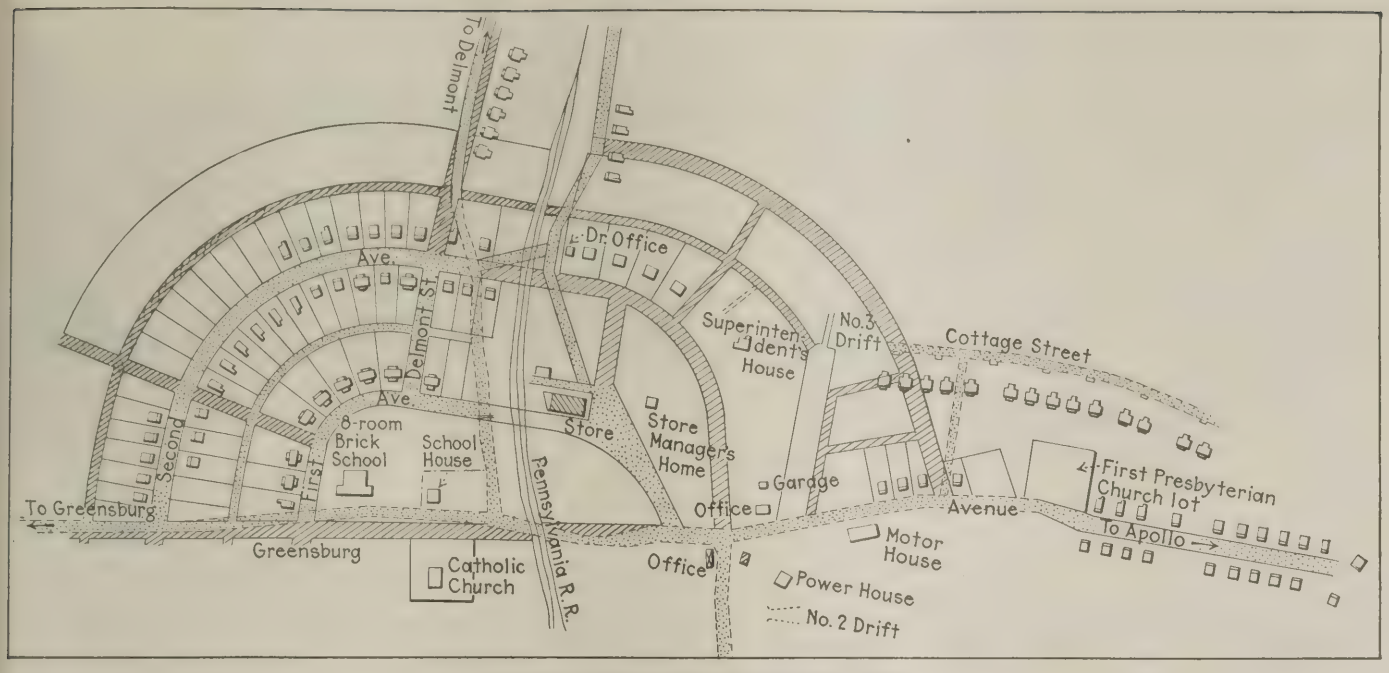
FOREMEN'S HOUSES ON APOLLO ROAD

It will be noted that care has been taken to leave enough trees to give the village an appearance of long establishment and the setting which every house needs. The houses are fully provided with plumbing fixtures.

The town of Slickville dates from the year 1916, at which time the town site was laid out, the 1,200 acres comprising the company's holdings having been acquired about 1900. The surveys were made in June and July, 1916, and the first mine opening was made in the autumn of the same year. At that time no railroad had been constructed to the property to be developed, so temporary buildings were erected for housing the employees.

All plans were based on the needs of a mine capable of producing about 3,000 gross tons of coal per day, this being the present capacity of the tipple, though from time to time the output has been increased to 3,100 gross tons. The Pittsburgh seam, the thickness of which on the Cambria property averages about 84 in., lies close to the surface in this locality, and at some near-by mines the coal is removed entirely by stripping. At Slickville, however, most of the work is underground; only a small area has been stripped, about 3,000 tons of coal having been thus obtained.

It was intended to bring the project to rapid completion and the work was expedited as much as possible. The only obstacle was that due to a lack of labor which was even then severely felt, though the United States at that time had not become a participant in the war.



At the present time about 500 miners are employed at the mine, making the total population of Slickville about 1,200 to 1,500. The plan of the townsite, which forms a part of this article, shows the houses and buildings which the company has constructed.

All the houses are of frame construction and of the "ready-cut" type. The erection of the first permanent dwellings was started in 1917, at which time the nearest railroad connection was Saltsburg, five miles away. Material for ten double houses which made room for twenty families was hauled from this point.

These double houses which measure 24x40 ft. exclusive of porches, are provided with two stories. On the first floor of each side are a large living room and kitchen and on the second floor are three bedrooms of fair size which have plenty of closet space. Bathtubs are provided and provisions made for the supply of

*Since this article was received the Cambria Steel Co., as also the Midvale Steel & Ordnance Co., with which it was affiliated, has been merged with the Bethlehem Steel Co.

Note—Headpiece shows houses of foremen and mine bosses on the road to Apollo. These have the Sanisept system of sewage disposal. Houses measure 22x25 ft. exclusive of porches. Trees, lawns and fowers give to the houses an air that private ownership alone is believed to confer.

PLAN OF VILLAGE OF SLICKVILLE

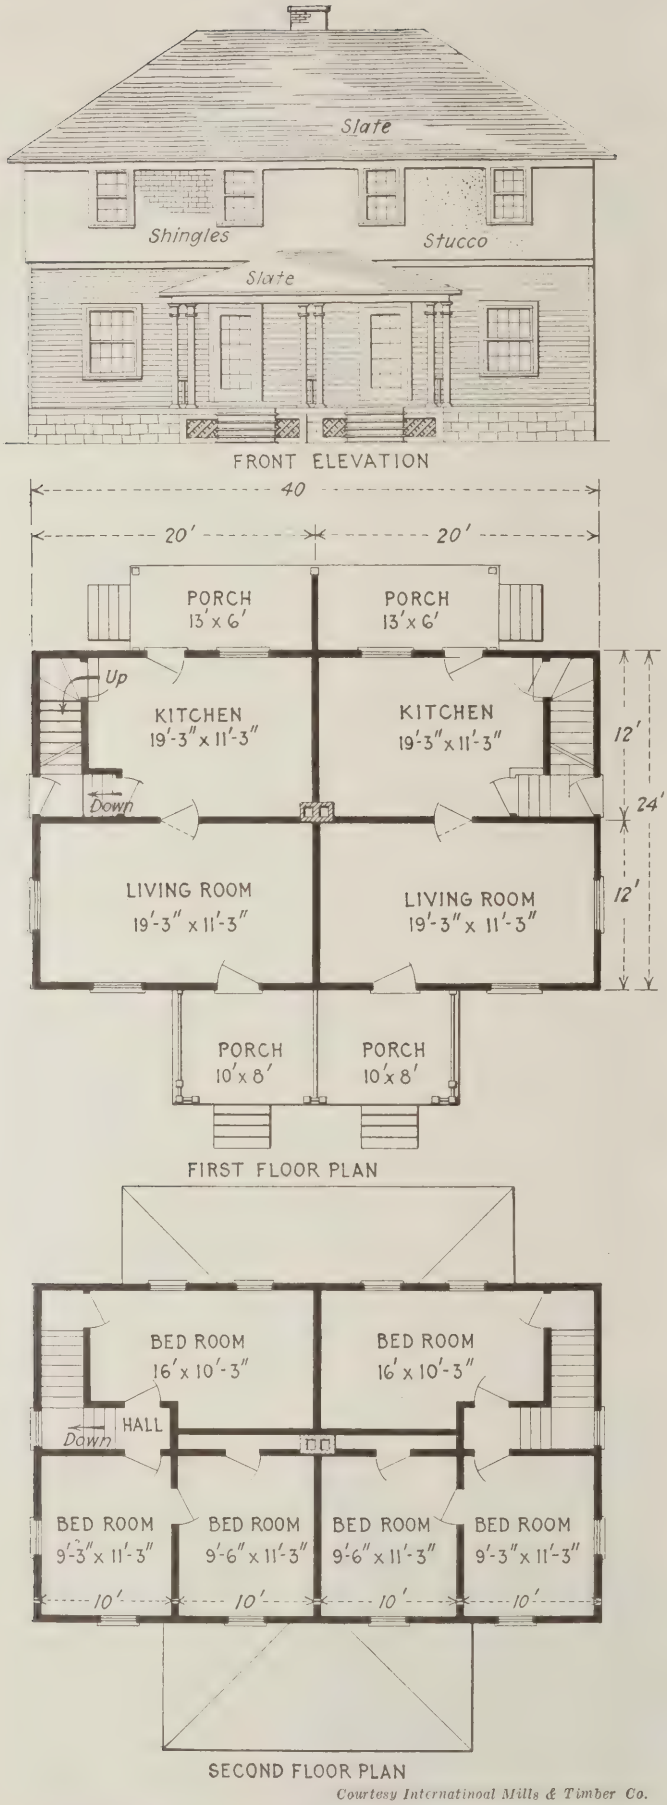
The stippled areas show the roads as at present used. An effort has been made to avoid long, straight lines, which are monotonous and none too sightly. Nearly every lot has its service lane at the back so that coal can be stored in the rear of the lot. The road from Greensburg to Apollo runs through the village approximately due north.

hot water. These houses have outhouses provided with concrete vaults.

It is interesting to note that all the houses on the First Ave. circle were built under wartime conditions when there was a great shortage of labor. As a result it was necessary to bring the men out of the mine to complete them, and even the blacksmith took a hand in the work. Hence it can be said that much of the town is self-built.

In 1918 twenty single two-story houses, each measuring 22x22 ft. were erected. All of these are on Second Ave. A living room and kitchen on the first floor and three bedrooms on the second floor is the standard arrangement. A bathroom also is provided on the upper floor.

Another group of houses similar in every way to those built in 1918 except that the dimensions are 22x24 ft. were constructed in 1919 for the use of the foremen and mine bosses. It was still necessary to haul material for this third operation over the public roads, but by this time the railroad was within three miles and shortly thereafter entered town, so that the necessity of hauling material long distances no longer hampered construction. All the houses built in 1918 and 1919 were provided with the Sanisept system of sewage disposal.



The year 1919 marks the beginning of the period in which the village began to take on the semblance of a completed town. In this year a large modern brick store building was erected. It is owned by the Cambria Steel Co., but is leased to and operated by the Miners' Supply Co., a stock organization. A complete line of groceries, general merchandise and meats is carried, and the store is provided with its own refrigeration plant. Here also is located the post office, which was raised from fourth class to third class rating in July, 1922.

The store is operated on a strictly competitive basis, the appeal to customers being based on the cleanliness of the surroundings, the completeness of the stocks and the low prices. It always has been well patronized,

Double Houses

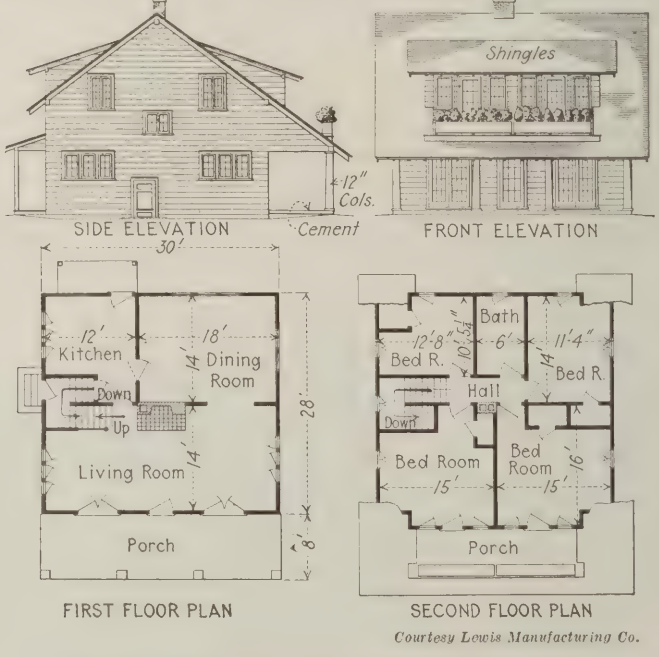
A crescent of double residences on First Ave., taken from the hill in front of the school. The tenants in these houses pay only $7.50 per month for rent, $1.50 for electricity, $2 for coal and nothing for water. Each half house measures 24x20 ft. and has a living room, a kitchen, three bedrooms, bathtubs and water heaters.

Courtesy International Mills & Timber Co.

FIRST HOUSES IN TOWN ON FIRST AND SECOND AVE.

These houses, shown also in another illustration, measure 24x40 ft. and accommodate two families. The foundation is of stone and the roof of slate. The outhouses are furnished with concrete vaults. The men were brought out of the mines to build these houses, as labor was scarce. However, being ready-cut houses about all the qualification the men needed was to know how to drive a nail.

SINGLE HOUSES ALONG APOLLO ROAD

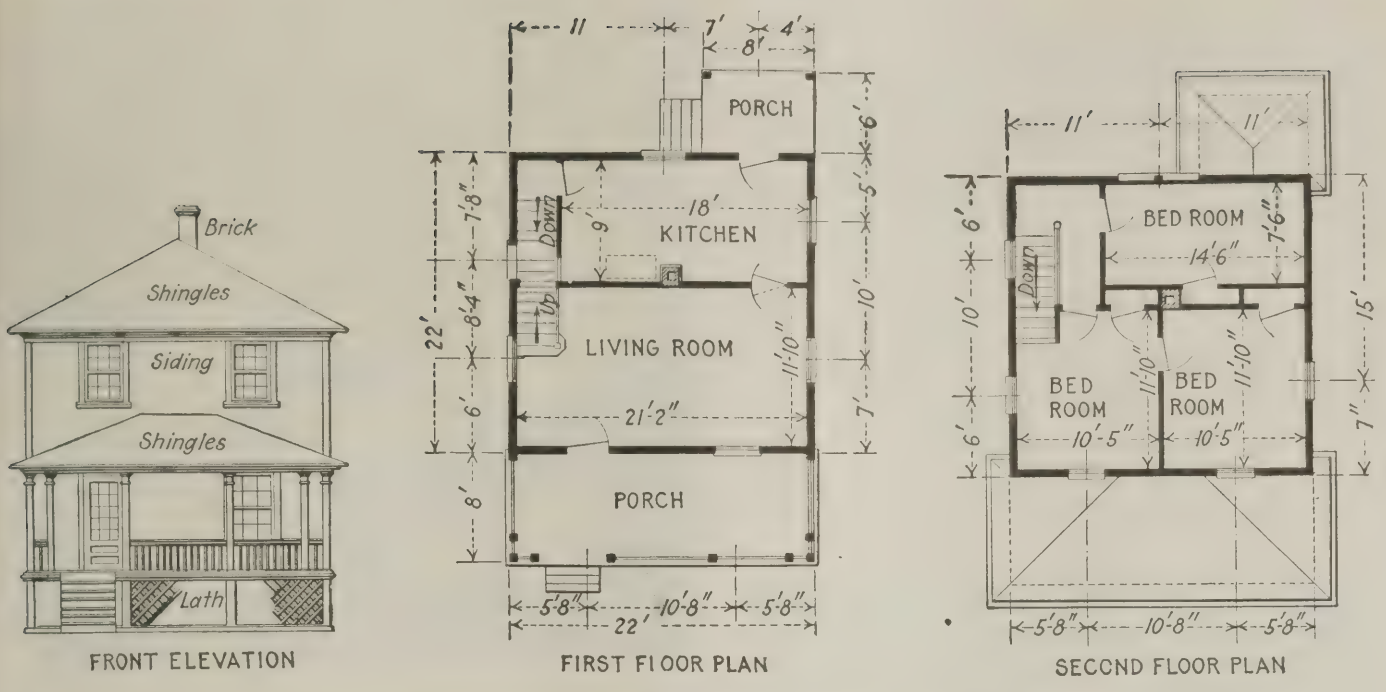


These houses rent for $10.50 a month, clearly exhibiting how little of the mine workers' earnings is devoted to rent. The urban worker often spends as much as 30 per cent on this item alone.

though no attempt has been made to prevent the construction of rival stores or like accommodations, of which there are some fifteen at the present time. The aim is to handle the best of everything, and the store is a credit to any community of the size of Slickville and many larger places. It is a "going" proposition in every sense of the word and pays a reasonable return on the investment.

In 1919 provision also was made for the housing of the various mine officials, a number of dwellings of better grade being erected in a westerly direction from the store. These measure 28x30 ft. and have seven rooms and bath. Individual garages also are provided with each house. The superintendent's house is of slightly different design but the same general type.

In 1920 a fourth group of twenty single houses, each containing four rooms, was erected. These have no bathroom but are provided with running water and with a toilet on the back porch.



The fifth and last group of houses built to date was erected in 1922 more or less as an emergency. These houses are all five-room one-story single houses and are not provided with an inside water supply. One hydrant between each two houses provides the tenants with

Courtesy Lewis Manufacturing Co.

SEVEN-ROOMED HOUSE FOR MINE OFFICIALS

These lie to the north of the store, that is to the right of it in the plan. The upper floor has four bedrooms and a bathroom. The rooms have plenty of closet space. Each house has an individual garage.

SINGLE SHINGLED HOUSES ON SECOND AVE.

These houses have 7-ft. cellars with 12-in. walls. Similar houses, but measuring 22x24 ft., were built for firemen and fireboses. In all these houses the Sanisept system of sewage disposal has been provided.

water. The outhouses are fitted with concrete vaults. An inside water supply was not provided because it was feared that owing to the type of construction the pipe would be likely to freeze. Six of these houses are located on the road to Delmont at the west side of town, and the remaining fourteen, on Cottage Street in the northwestern part of the village.

SPECIALLY DESIGNED RESIDENCES FOR OFFICIALS

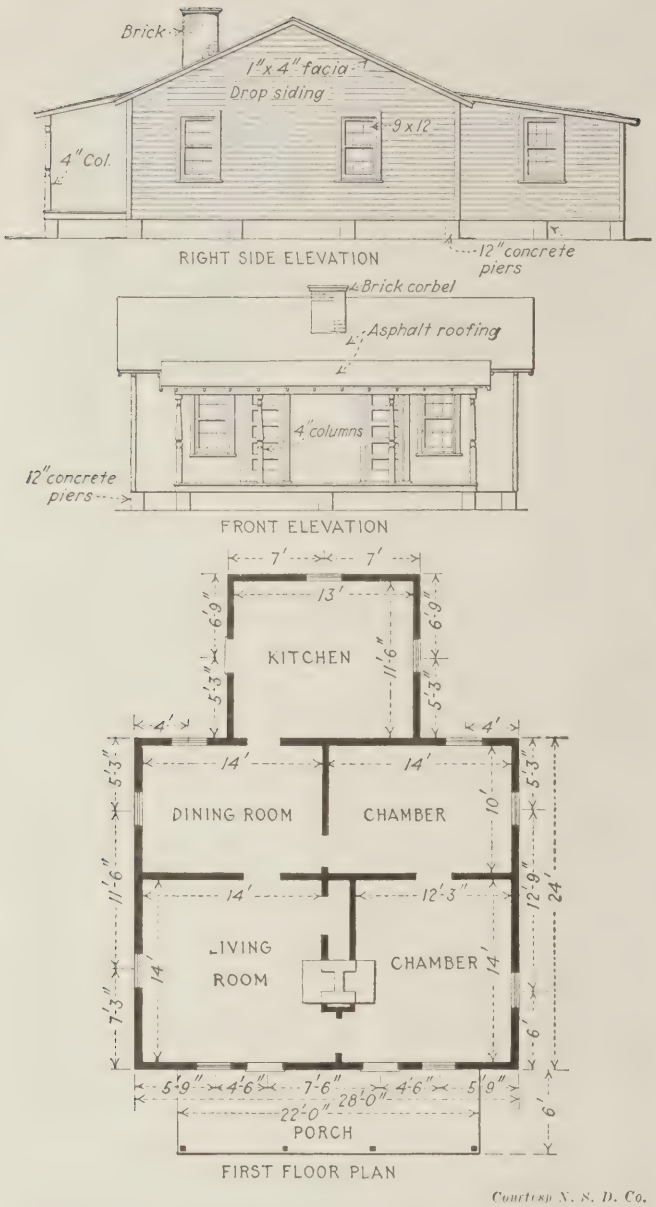
These were erected in 1919, when the railroad was being finished. They measure 28x30 ft. and contain six rooms and bath. They rent for $15 a month.

All the houses are lighted by electricity, the company furnishing the current. The steel company also supplies the coal used by the tenants. Every effort is made to keep these residences in the best of condition, the company keeping a plumber on the job whose duty it is to take care of all minor troubles. Likewise whenever necessary a carpenter is provided to make needed repairs.

The rental of the houses is quite reasonable. No attempt is made to make the investment profitable, the feeling being that the main reason for their existence is to provide housing of such a character as will form an invaluable asset to the mining operation. Indirectly the houses do pay for themselves, because contented help makes for better work. All rentals are figured on a base price for a given type of house plus a flat charge of $1.50 per month for light and $2 for coal. An idea of the low cost can be gained from the figures in the table herewith.

HOUSE RENTS IN VILLAGE OF SLICKVILLE, PA.

Type of House		Rent per Month
Double houses, built 1917 One side	Base	$7.50
Single houses, built 1918	Base	9.00
Single houses, built 1919	Base	10.50
Single 4-room houses, built 1920	Base	8.00
Single 5-room cottages, built 1922	Base	6.00
Officials' houses	Net	15.00
Superintendent's house	Net	25.00
Store manager's house	Net	25.00



In 1922 a modern eight-room schoolhouse was completed and opened at the beginning of the fall term. This was built by the township, is steam heated and has its own Sanisept sewage disposal system. At the time the school was opened the old two-room structure previously used was abandoned and bought by the Cambria company, which refitted it as a bunkhouse for floating help and provided it with a shower bath.

At the present time there are two church organizations, both active. The Roman Catholics completed a church structure in 1920. The Presbyterians have a lot selected on which they plan to build in the near future.

Other company buildings include the doctor's office, a one-story brick building located close to the railroad station at one end of the row of officials' houses, and the company office. This latter is a two-story brick building which houses the various executive and engineering offices and also contains a jail in the basement.

Village Has Not Been Incorporated

Slickville as a community is directly under the management of the Cambria Steel Co. It is not an incorporated town or village and there are no local officials. Despite this, however, the attitude of the company is not paternalistic but rather co-operative in its nature. No attempt is made to interfere with private initiative of a legitimate character, as has already been evidenced

Courtesy N. S. D. Co.

FIVE-ROOMED BUNGALOWS ON POST FOUNDATION

These houses, which were erected in 1922 to meet an emergency, have a living room, dining room, kitchen and two bedrooms. An outside hydrant provides water for two houses. The outhouses have concrete vaults.

to some extent in the mention of the general store and its competitors.

A well-defined scheme of welfare work has never been planned or attempted. When the town was started the war interfered with activities of this character, and since that time the feeling has been that it was not needed. The company, by furnishing good houses and maintaining them, has stimulated a sense of pride in the residents and encouraged it by co-operation in other ways which do not impose on the independence of the individual. From the results obtained this policy has been more than justified.

A few of the things that the company actually does are as follows: (1) All the lots are provided with gardens. The company plows them and furnishes the necessary manure from its stables. On the whole, good care is bestowed on the garden plots and this effort is fully warranted. (2) The company backs a boy-scout troop which at the time this article is written has a registered membership of thirty-nine. John D. Martz, principal of the school, is scoutmaster and has a fine group of interested boys. Work of this kind is more than worth while in any community, but to be developed to its fullest extent it requires a head who can give lots of his time to it. In recognition of this fact the company has made a practice of allowing a small additional stipend to the principal over and above his regular salary which is paid by the community.

Almost everyone today recognizes the value of scouting, and the writer, as a former scoutmaster with some

RESIDENCE OF THE SUPERINTENDENT OF THE PLANT

This house rents for $25 a month. Where houses are erected for profit and are located near urban centers but still in more or less open country, the rent of such a house as this would be at least three times as high.

six years of experience, desires to emphasize the fact that in his opinion there is no single activity that has to do with boys that is more productive of lasting results. Even at times when those who are interested fear that their efforts have failed, an accidental discovery will show that this conclusion is fundamentally unsound, and in some instances the reaction is of a surprising nature.

The girls have not been overlooked, and a girl-scout troop under the leadership of Miss McKee, a teacher in the school, who is assisted by Miss Martz, a daughter of the principal, was started this year and now has a membership of sixteen.

OFFICE OF CAMBRIA STEEL CO., SLICKVILLE, PA.

This two-story brick building houses the various executive and engineering offices. The sheriff maintains a jail in the basement.

Recently both girls and boys were given a chance to show the value of their training when the school directors' meeting of Westmoreland County was held at this place. The ladies prepared the meals in their homes, and the youngsters aided in delivering, serving and handling with great success.

(3) *Safety Work.*—A large proportion of the safety work is handled directly through the schools in the belief that the fathers can be more easily reached in this

EIGHT-ROOM BRICK SCHOOLHOUSE

Large, well-lighted school replaces the old two-room structure that served the community prior to, and for a time after, the opening of the Slickville mine. It also has a private system of sewage disposal.

way. As a rule the children can advocate safety to their parents better than any outsider.

Many activities are carried on independently. Among these are a basket-ball team. Moving pictures are shown three times a week and there is also a dance hall.

The general result is that here is a small mining town where living conditions are particularly favorable to contentment. It is not too far away from a large town (Greensburg, the county seat), and the local surroundings are far better than can be found in many similar places. The locality is an attractive one, in the midst of a wooded, hilly section, and the streets of the town in summertime are particularly attractive because of the many trees which have been left standing.

The miners themselves like the place, and few seem disposed, after once they have moved in, to continue to follow the impulses of their roving natures. Even during the recent strike, when, after a long time, it finally became necessary to terminate the leases of some of the miners who refused to go to work, there was no hard feeling, and the same men have since been hired again. In connection with this description of the town of Slickville it will undoubtedly be of interest to know something about the character of the mines and their operation.

This is a typical drift-mining operation with three openings at the present time, the coal being dumped over one tipple. Owing to the position of the seam much of the coal to be mined is what is known as "crop coal" and much timbering is required. In some places it will be necessary to resort to stripping. The roof consists of a rooster coal which in places is 18 in. thick and at other places entirely absent, giving place to slate. Over this is about 18 in. of banded coal and slate and over that again a real slate and limestone. Under the coal is a 4-in. layer of fireclay resting on a hard limestone.

Electricity is used throughout the mine and property, power being furnished from the West Penn Power Co.'s line. A combination transformer and motor-generator station takes care of all requirements. All electrical equipment on the tipple is driven by 220-volt alternating current which is transformed from 2,200 volts. All the mine equipment is actuated by 250-volt direct current from the motor generator. In addition some current is transformed to 110-volt alternating current for use in the town, thus making possible the use of standard electrical devices in the homes. For night work in the mine a small motor-generator set takes care of all requirements.

SLICKVILLE HAS ITS TROOP OF BOY SCOUTS

John D. Martz, the principal of the school, is scoutmaster and has a group of thirty-nine greatly interested lads. Many a town is ruined by the misdirected activities of its boys and many another is given a quality of stability by the helpful influence of well-trained youth.

FIRST FLOOR OF STOREHOUSE

Time was when the mine foreman's shanty was the storehouse. There were only a few parts to keep, but even then they often were lost. The growth of mechanization has made storehouses necessary. This one is of brick. This, the first floor, is used for the storage of machine parts.

There are no special features of interest connected with the inside work of the mine. Steel mine ties are used in all rooms and 5x6-in. or 5½-in. wooden ties with 70-lb. rails are used on all main haulage tracks. Four 6-ton gathering locomotives and also horses and mules are used for gathering. On the main hauls three 13-ton and two 6-ton locomotives are used.

The cars used in this mine are of the same size as those used in thin coal. Cars of this size can be more conveniently handled in case they are derailed inside the mine, and even though no locomotive is immediately available for their rerailing. This quality more than offsets any losses due to decreased carrying capacity. The cars are of an all-steel pressed-body type with special patented features designed by Mr. Lubken, then general superintendent of the coal-mining operations of the Cambria Steel Co. These were illustrated in an article by the author on the Rolling Mill-Rosedale Mines at Johnstown in *Coal Age* of Sept. 7, 1922.

Tipple

This structure was built wholly from timber either sawed on the company's land or brought in from nearby mills. It was erected before the railroad was completed. The cars are discharged by rotary dumps and returned by kickbacks.

The tipple is of wood, all the timber for its construction being sawed on the company's or adjacent property. It was built before the railroad to the mine had been completed. All cars are discharged on rotary dumps, and kickbacks are used to return the cars.

From the dump the coal goes to crushers, the sizes under ¾ in. being bypassed directly to the loading-out chutes. The lump coal is crushed to sizes between ¾ in. and 3 in., all slack less than ¾ in. being screened out. None of the coal is washed. The slack is used in the coke ovens at Johnstown and the larger coal in the gas producers at the same place. In this connection it should be mentioned that the local Johnstown low-volatile coal is not a coking coal in itself, and it is necessary to mix it with gas coal to produce a coking mixture. This was one of the reasons for acquiring this property. Near the tipple is a small pumphouse containing an electric pump which lifts water from a 90-ft. well for use in the town and plant.

Method of Keeping Track of Men and Tonnage

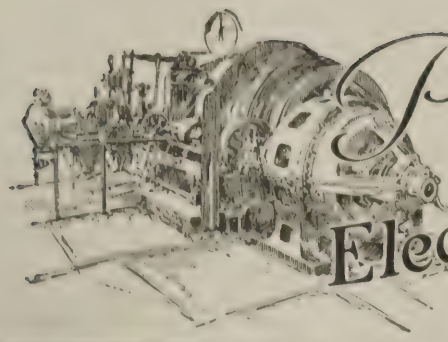
Each miner has two checks. One is an identification check that he always keeps with him regardless of location. The other is the usual time check which is dropped in a box in the time office on the way into the mine. The timekeeper records it and then hangs it on a board where the man can get it again when he comes out. Numbers are assigned according to the mine, a special set being reserved for men working on general company work.

In an operation of this size the dispatching of coal cars is not a difficult problem. It is handled by the locomotive boss, who is responsible for the motormen being on hand and who also keeps tabs on trips. Each motorman reports on a blackboard the number of cars handled on each train. The locomotive boss knows what tonnage should come from each section and in this way allots the necessary empties. Every hour the number of tons dumped from each mine is telephoned from the tipple to the office.

Each week is held a company meeting which is attended by the various bosses, foremen and officials, and here all questions of policy, problems of operation, etc., are thrashed out. The storehouse is a two-story brick building and is a model of its kind. On the first floor all machine parts are stored, being kept in numbered bins. Each part has its own place, and the bins are grouped by machines. On the second floor bolts and miscellaneous materials are stored. Separate bins are used for bolts and all small articles.

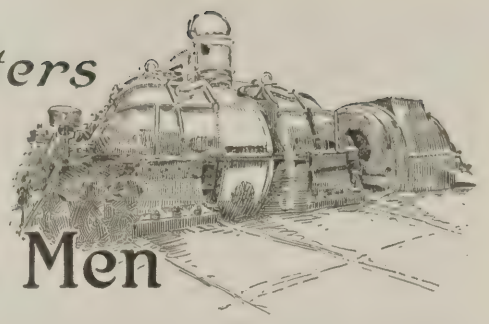
In accordance with usual practice the cap house, which is of brick, is located at one end of the storehouse and the powder house is at the other end. These buildings carry about a day's supply, the balance being stored in separate storehouses in the valley back of a hill that bounds the town. An interesting feature of the powder house is the absence of light or heat inside. The only source of illumination is an electric light over the window through which the powder is passed out, making the storage as nearly safe as possible.

Oil pumps and sunken tanks are used in the oil house, which is provided with one 500-gal. tank for machine oil and one 1,000-gal. tank for crude oil. Both are set in concrete. This has been found to eliminate much waste. Before these reservoirs were installed, raised tanks were used, and someone was always letting the oil drip or run, no matter how much that practice was deprecated. The oil house is not heated.



Slickville forms an interesting example of the trend of modern mine management. The property is one which is good for at least twenty years of operation based on present capacity, and plans have been made with this in view.

Jarring Blasts Save Lives from Blowouts



By F. C. Cornet

TWO methane outbursts of great violence, both killing men and doing great material damage, occurred in Belgium in March, 1923. One was at Paturages, the other at Quaregnon. They brought to a climax the controversy, between the operators on one side and the Department of Mines on the other, regarding the demand of the former that they be permitted, at the working faces, to use the jarring-blast method of initiating blowouts. Public opinion and the press took the side of the operators. So did the miners' union. The Department of Mines authorized a three-months' trial of the jarring blast in part of the Mons district.

The operators wasted no time and immediately introduced in their mines the long forbidden method. During the first week of the present month (April, 1923) a blowout of the first magnitude provoked by a jarring blast occurred in the Rieu du Cœur Mine, at Quaregnon. It killed nobody, as the men had left the mine, the shots being fired from the surface. The damage was estimated at less than $20. The operators of Belgium now feel sure that they will be permitted permanently to use the jarring-blast method of operation wherever it is advisable to do so. It long has been regarded in France as a life-saving provision.

Practical Pointers for Electrical and Mechanical Men

Voltage and Load Control of Alternators

IF AT any instant the electromotive force of one generator is lower than that of other machines with which it is connected in parallel, it will take current from the other generators instead of feeding current into the line.

That the electromotive forces may be the same at all times, the generators must conform in frequency, phase and wave form, otherwise pulsating currents will be set up. If similarly designed machines are adjusted for the same voltage and operate at the same uniform speed, these conditions usually are fulfilled.

The distribution of the load on alternators operated in parallel is determined by several factors, the primary one being the speed. If the governors on the driving machines give different speeds, that which runs at the greater speed will carry a greater proportion of the load until the speed is reduced, when the second machine will begin to carry the load. Before this condition is reached one generator may be running as a motor, as the tendency is for the speed to be higher than it would be if it were not running in parallel.

The effect on the engines of a periodic transfer of load occasioned by hunting between two machines running in parallel is somewhat similar in effect to throwing the load on or off a single engine at short equal intervals which may be measured by one or several pulsations in the combined turning efforts applied to the engine shaft.

In some extreme conditions the pulsations of load may amount to more than the normal capacity of either machine. With no external load one engine may then alternately drive the other, which evidently will be a more severe condition than if the load were only applied and removed from a single engine.

Different than with direct-current generators, when the rheostats of two alternators running in parallel at normal speed are not adjusted to give proper excitation, an idle or cross current will flow between the armatures, the value of which will depend only upon the difference in field charges of the machines. This cross current may vary over a wide range, from a minimum of zero when both field charges are normal, to more than full-load current when they differ greatly. The effect of this cross current is to increase the temperature of the armatures and, consequently, to cut down the output of the generators. It is important, therefore, that the rheostats be so set as to reduce the cross current to a minimum. This cross current is registered on the ammeters of both generators and usually increases both readings. The sum of the ammeter readings will be a minimum when the idle or cross current is zero.

In general, the proper field charge of a machine running in parallel with others is that which it would have if running alone and delivering its load at the same voltage.

In order to determine the proper position of the rheostats it is necessary to make trial adjustments after the alternators are connected in parallel until that position is found which reduces the sum of the ammeter readings to a minimum for a given load.

It is therefore obvious that by a combination of changes in the two rheostats—i. e., by cutting one in and the other out at the same time—the strength of the cross current may be varied considerably while the electromotive force of the system remains constant, and the load will be divided between the two machines practically the same as before, because, as pointed out above, the division of the load is a function of the speed at which the prime mover drives the generator.

Welding Cast Iron

ONE of the most difficult welds to make is a cast iron weld. The welding process forms a layer of extremely hard metal with low mechanical strength just under the deposited metal. This prevents a proper knitting together of the cast iron and welding material, which causes failure to take place in this area. To overcome this condition several methods have been developed, some of which are fairly successful. One method is to prepare the specimen for welding and then drill and tap the area with holes into which stud bolts are screwed. The stud bolts are left projecting out of the cast iron and the weld is made to the cast iron and studs. By this method the studs serve to tie the deposited metal to the specimen.

Another method is to make the weld with a non-ferrous electrode, such as bronze of certain alloy and copper nickel alloy. These metals deposit without the hard film referred to, and if properly done the weld will show high mechanical strength. Positive polarity in the electrode should be used for non-ferrous electrode work.

Reducing Voltage in Synchronous Converter For Locomotive Battery Charging

CONSIDERABLE economy may sometimes be effected in charging storage battery locomotives by the use of a three-wire synchronous converter. When the trolley voltage is 250 and the battery charging voltage is about 125, obviously it is necessary that the trolley voltage of 250 be reduced by some means. Frequently the voltage reduction is made by inserting resistance in series with the battery or by the use of a motor-generator set.

Both these methods are relatively expensive, due to

power loss and outlay for equipment. The three-wire synchronous converter may be used to great advantage. The neutral point usually is obtained from the middle point of the low-tension winding of the transformers or from auto-transformer balancing coils if the converter is used without step-down transformers. Series field windings on main poles and commutating poles, if any, are divided into two equal circuits, one connected in each main lead. This is necessary to obtain proper excitation with unbalanced direct-current loads. The result obtained will be 125 volts between each main lead and the neutral wire, this voltage being that required for charging most storage batteries used on mine locomotives.

Polarity, Composition of Electrodes and Adjustments for Luminous Arc Headlights

THE popularity of the luminous arc headlights for mine haulage locomotives is still well established, yet there is some confusion with respect to the polarity of the electrodes. With incorrect polarity it is possible at times to get seemingly satisfactory results for a time and it is for this reason that the incorrectness of polarity is not quickly and readily realized.

Incorrect polarity will not give the proper volume of light; the arc is unstable and of a greenish color. With correct polarity the arc gives a brilliant white light and burns steadily.

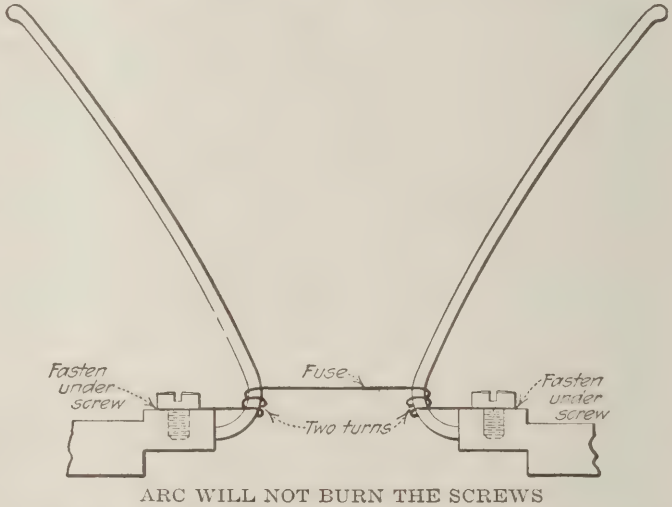
The upper electrode is a copper composition and the lower electrode is a magnetite composition. When properly connected to the circuit the upper electrode is positive and the lower electrode is negative.

Every arc is characteristic of its negative electrode—that is, the negative electrode determines the quality and color of the arc. When a new lower electrode is put in the headlight, it should be burned for about five minutes before being sent out on a locomotive. This time is necessary to burn off the iron cap on top of the electrode, during which time the arc is somewhat unstable.

After the electrode has burned for some time the top becomes a molten mass, and when it cools the end becomes hard and uneven. When the headlight is put in operation again, this readily melts. The end should never be knocked off.

The electrodes of luminous arc headlights burn a very long time. The upper (positive) electrode has a life of about 2,000 hours on 4-ampere headlights and about 3,000 hours on 2-ampere headlights. Therefore it is rarely necessary to adjust it more frequently than every two or three months. The lower electrode (negative) has a life of 75 to 100 hours on 4-ampere headlights and 150 to 200 hours on 2-ampere headlights; after ten hours' burning it should be adjusted.

Many users of the luminous arc headlight have found it to be so satisfactory in operation, when connected with the proper polarity, supplied with the correct electrodes and properly adjusted that whenever any difficulty is experienced they immediately check up on these points and almost invariably find the cause of the difficulty.



Wrong polarity occasionally is found to exist when the headlights come in on a new locomotive, and if not properly corrected on putting the locomotive in operation this condition may exist for an extended period, giving poor operation and being wasteful of electrodes. This may be due to the fact that the locomotive is placed at work in a section where no one is familiar with the headlight and also because the electrician rarely thinks it necessary to give a new locomotive a great amount of personal attention during the first year of its life.

Improper electrodes will greatly affect the stability of the arc and in checking into this detail some very interesting and strange things have been found in headlights used on locomotives which have been in service for long periods in remote sections of the mine. Copper trolley wire has been used for an electrode and even rail spikes have been used. These substitutes cannot give the proper light and frequently result in damage to the headlight and accidents on the haulage system entailing expense that would pay for obtaining and installing the proper electrodes.

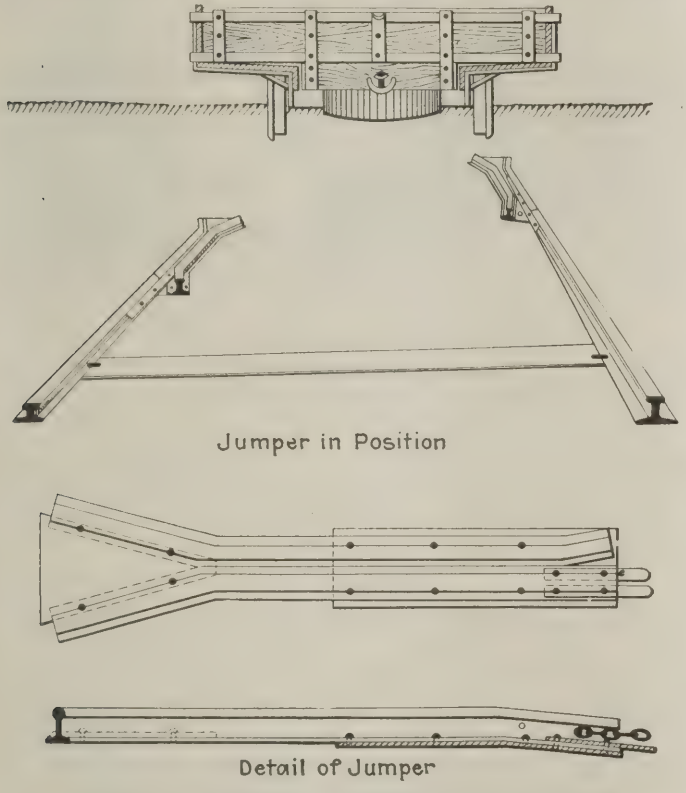
The adjustments to the electrodes should be done regularly; this does not inflict any undue burden upon anyone because the inherent characteristics of the headlight automatically maintain proper adjustment for over ten hours of service.

How to Fuse a Horn Gap

IN A large number of relatively low-voltage alternating-current distribution lines the horn-gap fuse is most popular. Its advantage is that it does not require any cumbersome piece of equipment when it becomes necessary to re-fuse the line after some condition has arisen which has blown the fuse. However, a troublesome feature in connection with the horn-gap fuse is that the fuse wire is held under a screw or some form of wing nut which in the rupturing of the fuse very often becomes burned or welded fast by the arc following the fuse wire back to the screw while opening the circuit. This condition is very annoying and troublesome to the repair man who must sometimes renew the fuse in inclement weather and under inconvenient conditions on the top of a pole or on a dangerous switching tower.

ARC WILL NOT BURN THE SCREWS

Melting of the fuse carries the arc to the horns where it raises and stretches until broken and thus ruptures the circuit.



The method for fastening a fuse shown in the figure easily prevents the arc from burning the screw. It will be noticed that the fuse wire is wrapped around each horn before being attached under the screw. When the fuse is blown, the arc follows the fuse wire back to the horns and then goes up the horns, leaving the screw untouched.

New Equipment

Rerailing Device in Room Permits Car To Be Placed Near Working Face

MUCH energy is wasted at the working face whenever coal is loaded by hand. The actual work accomplished in foot pounds may be calculated by multiplying the net weight of the load by the height of its center of gravity above the bottom. Because in loading the coal must be tossed to a level higher than the side of the mine car and must be given energy of translation, much useless effort is expended. By bringing the mine car close to the face this can be remedied in part, for the distance the coal has to be thrown is thereby reduced.

A track device which may be used in a room or heading was patented recently by the Skinkle Mine Car Jumper Co., of Huntington, W. Va. By its use an empty mine car can be pushed off the end of the track and over the bottom to a position as close to the face as will favor the loading of coal. Whether animals or locomotives are employed in gathering, little difficulty is experienced in rerailing a loaded mine car over and through the rerailers and onto the room track beyond; especially is this device practicable where mining leaves a smooth, hard floor which expedites the movement of the mine car from the face to the track.

FROGLIKE JUMPER TO RERAIL CAR AT FACE

In England cars are quite frequently removed from the rails near the face. With the jumper shown the rerailing is easily accomplished. Steel plates would make this provision for easy loading feasible even where the bottom is soft and the car has to be run along the working face. This would avoid double shoveling, which in low coal is distressingly hard work and always destructive of coal of large size.

As shown in the figure, the two jumpers are fishplated each to the end of one of the rails. These may be attached one in advance of the other wherever the ends of the rails used at the face fail to be opposite. With two wheels on one rail and two on the smooth bottom the mine car will move in line with the track and completely rerail when the rerailing device on the other rail is reached. In fact, it might be well to lay the room track at all times so that one of the two jumpers will be slightly ahead of the other, for in that case the guard rails will guide the wheels until all four are on the track. Whenever a locomotive goes into a room thus equipped to pull out a car, it must of necessity be provided with a short towline for pulling the loaded mine car onto the room track

Enclosed Room Hoist Is Safe, Sturdy, Easily Portable and Convenient

TO MEET the ever increasing demand for a completely guarded room hoist, the Flood City Mfg. Co. has developed a totally enclosed steel frame hoist which besides meeting all the requirements of the mining and compensation codes, embraces several desirable features not heretofore found in hoists of this type.

Fig. 1 shows the completed hoist, on which no moving parts are exposed. The opening for the rope is provided with rollers at either side which guide the rope on the drum and protect it from being cut or damaged by the plates should the load not be directly in front of the hoist. The brake lever and clutch lever are placed at the side within convenient reach of the operator.

Fig. 2 illustrates the left side of the hoist, showing the construction of the gears and friction. One of the very desirable features of this hoist is the cone friction clutch which consists of a wood friction block bolted to the drum and which engages in a machined surface on the inside of the rim of the main gear. Operation of the clutch is obtained by means of a steel screw working in a bronze nut. A suitable hand lever is provided for operating the screw. By operating a lever the drum shaft and drum are forced endwise, thus engaging friction. Release is obtained by a coil spring placed between the gear and drum. Bearings of both shafts are 2-in. bronze bushings, and are interchangeable. Lubrication is by means of compression grease cups accessible through holes in the frame.

For direct-current power, the motor is a standard

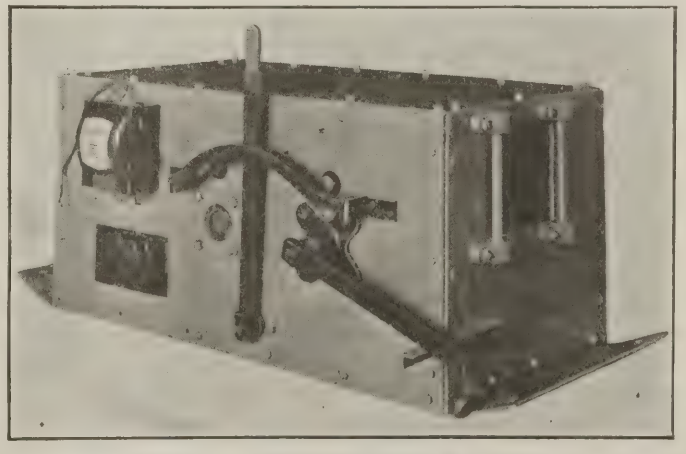


FIG. 1—BOXED-IN ROOM HOIST

The enclosing case makes the equipment safe and compact. The design of the bottom is such that the hoist may be skidded to a new location under its own power.

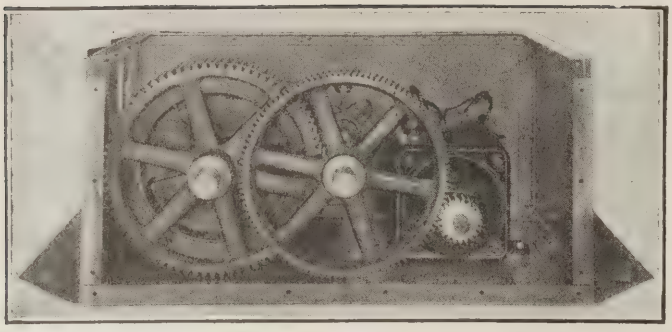

FIG. 2—REPAIRS AND INSPECTION EASILY MADE

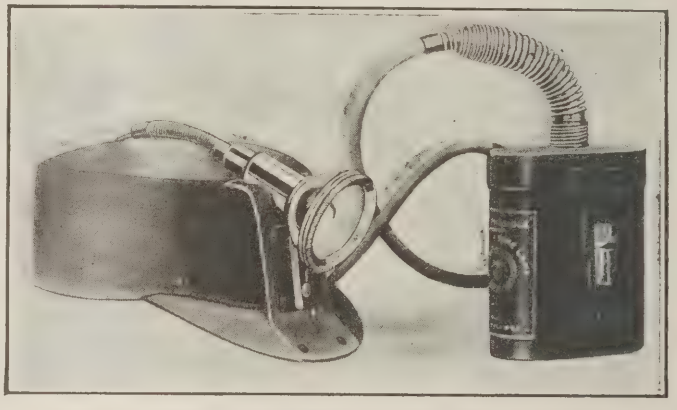
Top and side covers, when removed, give ready access to all parts. Foreign materials cannot get between gears and pinions. Unauthorized adjustments are less frequent.

compound-wound crane-type motor of any standard make. Control is by means of an enclosed fused knife switch which connects the motor directly to line. As the motor is always started without a load this is permissible and eliminates all control and resistance troubles.

For alternating-current power a wound rotor or high-torque squirrel-cage motor with fused knife switch is used. The hoist is geared to a speed of 100 ft. per minute, and with a 5-hp. motor will develop a rope pull of 1,500 lb.

With either drive the motor is started by closing the knife switch, and after the motor has attained full speed the clutch is engaged, which can be done by manipulating the lever in such a manner that the load is started without any jerk. By allowing the clutch to slip, the load can be moved at any speed or any distance desired.

Cap Lamp Having a Solid Electrolyte



ONE of the earliest of cap lamps was the CEAG, manufactured by the Concordia Electric Co. It scored a greater success in Europe than in America because of the preference in this country for a cap lamp. The British Home Office in a competition in 1912 gave it first place out of 197 lamps submitted. Europe did not object to using a hand lamp, and indeed the preference was all in favor of a lamp that could be so carried and that could be hung to a nail.

Perhaps it is too late to argue that Europe may be right. As a rule the workman is not to be argued with. He has his notions and refuses to try out what does not please him. Yet it may be said that the United States Coal & Coke Co. is having considerable success with stationary lamps. These, however, are ordinary electric bulbs supplied with current by wires connected with the power lines of the mines. They do not have to be carried into the mines with every shift, and have a higher candle power. As for the objection to carrying the lamp, that surely is not serious wherever the miner is transported almost to his working face on a man trip. When he has to walk in and out and carry a pick or two, a drill or a keg of powder and a dinner pail, any additional load is looked upon as an unbearable encumbrance.

It might be well to give the reasons why the hand lamp is regarded as preferable. It gives a more equally diffused light. The miner does not work with part of his coal in a glare of light and part in darkness. The light flux of the hand lamp can be made roughly twice that of the light emitted by a cap lamp. Then again hand lamps have a hook which makes it possible for the miner to work unimpeded by a cord. Furthermore, the battery is not dragging from a strap. When the electrolyte is liquid it is likely to be spilled if the battery is carried on the person, and men have been burned in consequence of this fact. Another advantage is that the one vulnerable part of the outfit is omitted—the cord. This item in the equipment, though now much improved, was in early days a source of much trouble. For these many reasons perhaps the last word has yet to be spoken as to the possibilities of the hand lamp.

However, the manufacturer cannot dictate. He has to follow prejudices as to construction even though he feels they are inadvisable. So the CEAG is being made for use as a cap lamp, and, what is more, one of the difficulties, that of leakage of the electrolyte in the battery, is being eliminated by the use of a solid instead of a liquid. This safety lamp was approved by the U. S. Bureau of Mines under the new schedule No. 10-A, it being the first to receive certification under the new ruling.

As the electrolyte is a gel no burns can be received, as is the case with a liquid, whether acid or alkaline,

CAP SAFETY LAMP WITH BURNLESS BATTERY

To prevent the possibility of leakage and to keep the electrolyte always effectively covering the electrodes the lamp is provided with a solid electrolyte. The battery is locked by a strong magnet and so cannot be tampered with.

the burns from an alkali being worse than those of an acid. Furthermore it always covers the electrodes, so that no matter what the position of the battery may be in operation the light given is the same.

Self-Cleaning Revolving Grizzly Which Requires Little Power to Drive

THE old fashioned "grizzly" is a grating of iron or steel bars which, at the coal mines, usually is known as a "bar screen." It does not do good work, for many a little pile of slack rests on the top of a lump of coal and slides placidly down the screen without realizing how narrow is the chance that keeps it from an early fall.

For this reason the revolving grizzly has been introduced, the bars being circular and the mine product being run over the outside of the circle. It is like a screen, but it has bars instead of a mesh, and the run-of-mine is run over the outside instead of the inside.

This grizzly in revolving turns the lumps over and does it in a few inches of screen travel. Slack will travel almost any distance over a bar screen, for the lumps are not disposed to turn over. However, it is an unfortunate fact that the revolving grizzly will sometimes take a piece of irregular coal or other material and turn it over till a small diameter is presented to

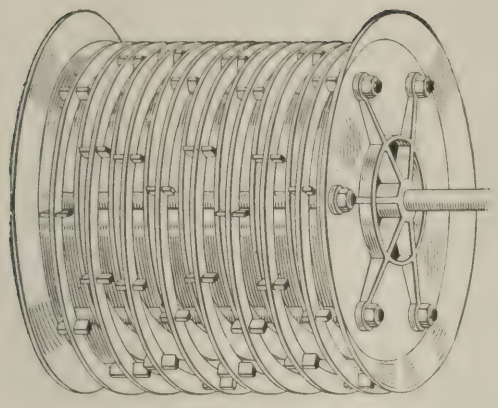


FIG. 1

PERSPECTIVE VIEW OF GRIZZLY

Note that the rings are all level at the top of the grizzly and far apart at the bottom, giving plenty of room for the escape of the material which has passed through the upper part of the rings into the grizzly. For this reason the device does not clog with screened material.

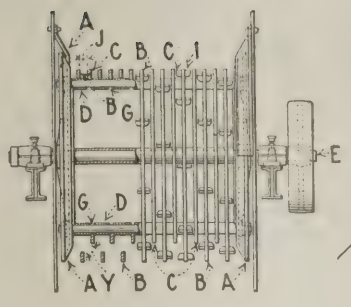

FIG. 2

CONSTRUCTION DETAILS

Here can be seen the spacers which keep the loose rings from spreading. They bear on the small rings. As these are firmly held by sleeves on the six rods they cannot get out of alignment.

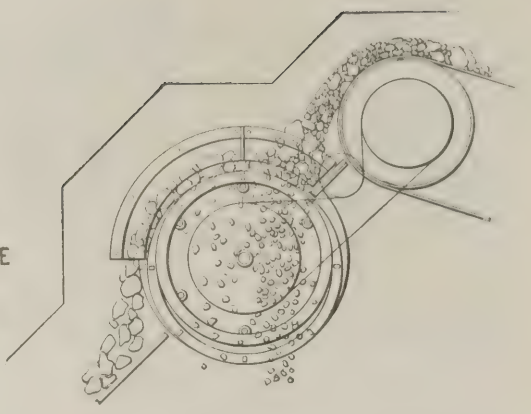

FIG. 3

SIDE ELEVATION SHOWING SCREENING

Here again can be seen the opportunity given for an escape of the screened material. The large rings are dangling all the time from what for the nonce is the uppermost rod. The opening, therefore, is largest at the lowest point in the grizzly. Such a device cannot fail to have large capacity.

the screen. That piece of coal falls into the grizzly but does not readily fall out until it has been lifted or rolled about. Several of these pieces are likely to load up the grizzly and oppose the passage between the bars even of pieces which are of the right diameter in all directions. This clogging of the grizzly increases the driving power needed and makes it necessary to shut down the machine till the obstruction has been cleared.

A new type of this device, shown in Fig. 1, which corrects the faults of the ordinary revolving grizzly, has been devised, its initial purpose being to screen copper ore. It was invented by Kenyon Burch, for the Copper Queen Concentrator, near Bisbee, Ariz.

Fig. 2 shows the details of construction. Two disks, or heads, *A*, are connected by a shaft, *E*, and six rods, *G*, are set in a circle somewhat near the periphery. The ends of the shaft extend through the heads for support on bearings and take the driving pulley, as shown. The screen rings rest on the rods. Some are of one and some of another diameter. The smaller rings, *C*, are held firmly in position by sleeve-like spacers, *D*, which surround the various rods, *G*, as can be seen best in Fig. 4. The larger rings, *B*, are kept in place by occasional spacers, *I*, but they swing free, and, consequently, though the rings are all at the same level at the top of the grizzly, that is anything but true at the bottom, the large rings standing well below the others at that point. In Fig. 2, *Y* and *C* represent the small rings which revolve with the grizzly and *B* represents large rings that do not so revolve. It can be seen, therefore, that any coal or other material trapped at the top of the grizzly is readily able to free itself at the bottom. For this reason the device is non-clogging.

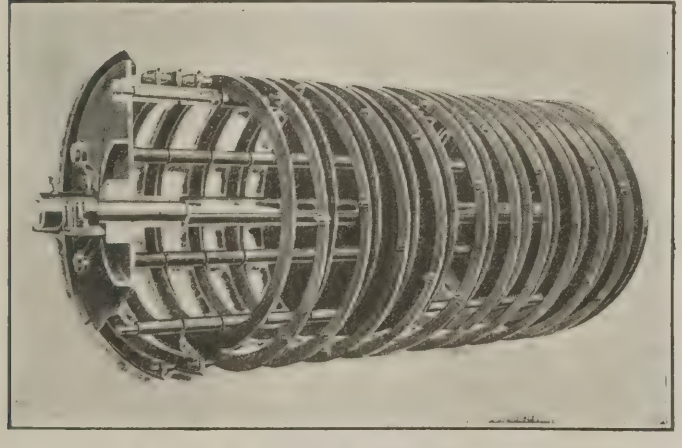

FIG. 4—BURCH GRIZZLY WITH RINGS PARTLY REMOVED

An excellent idea of the sleeves on the six rods can be obtained from this view. They hold the small rings firmly in place so that they cannot move sidewise from the position in which they have been placed.

Sales of Explosives Decline in February

Explosives manufactured in the United States and sold during February, 1923, according to reports to the U. S. Bureau of Mines, amounted to 588,556 kegs of black blasting powder, 4,460,178 lb. of permissible explosives, and 16,559,865 lb. of high explosives other than permissibles. These figures, based upon reports from companies that manufacture about 90 per cent of all explosives used in the United States, show increased sales of high explosives as compared with January, 1923, but reductions in sales of black powder and permissibles.

Sales of black powder during February were 28 per cent below the amount sold in January, 1923, 10 per cent more than February last year, 52 per cent more than February, 1921, and 28 per cent below February, 1920. During the first two months of the present year, 1,405,249 kegs of black powder have been sold, an increase of 34 per cent and 61 per cent, respectively, over the first two months of one and two years ago, but 18 per cent below the amount sold in January and February 1920. Of the total quantity of black powder sold in the first two months of 1923, 90.4 per cent was for coal mining.

Sales of permissible explosives in February showed a decrease of 17 per cent from the record for January, but an increase of 34 per cent over February last year, 74 per cent over February, 1921, and 14 per cent over February, 1920. The combined sales for January and February, 1923, have amounted to 9,836,548 lb., an increase of 60 per cent, 51 per cent and 18 per cent, respectively, over the two-month periods of 1922, 1921 and 1920. Of the permissibles sold in the first two months of 1923, 94.9 was used in coal mining.

February sales of high explosives other than permissibles were substantially the same as in January, an increase of less than 0.1 per cent being noted. As compared with February in previous years, however, the February, 1923, sales were 43 per cent more than February last year, 42 per cent more than February, 1921, but 9 per cent less than February, 1920. Of the high explosives sold in January and February, 1923, 18.6 per cent was for coal mining.

Problems of Operating Men

Edited by James T. Beard

Securing Capable Mine Officials Greatest Factor in Safety

Safety Circular of C. F. & I. Co., Approved by Bureau of Mines—Certifying Mine Superintendents —Efforts of Bureau of Mines to Educate Miners

ACCORDING to the letters of Robert A. Marshall, *Coal Age*, Nov. 16, p. 799, and W. H. Perdue, Jan. 11, p. 59, a circular was recently issued by the C. F. & I. Co., calling attention to certain things and making recommendations in the interest of safety. The circular was issued with the approval of the Bureau of Mines.

Among the recommendations contained in the circular was one urging "that all persons in responsible charge of the direct operation of coal mines, including superintendents, foreman, mine bosses and shotfirers, should be required to have certificates of competency issued by the state and showing that the applicant has passed an examination clearly establishing his knowledge of what constitutes up-to-date safe practices in the branch or branches of mine operations under his jurisdiction."

In discussing this question, Mr. Marshall remarked, "If the certifying of superintendents will make our mines safer I am for it heart and soul." Personally, it is hard for me to understand how the certifying of superintendents of mines would have any detrimental effect that would invite any opposition to such a measure. In Colorado,, the mine foreman is required to report to the superintendent for instructions and advice. For that reason, it is important that the latter official should have a thorough knowledge of underground conditions and requirements.

Without that knowledge, let me ask, how can a superintendent safely direct a foreman in matters pertaining to the work in the mine? It is true, I admit, that the Colorado law gives the mine foreman "full charge of all the inside workings and of all persons employed therein" (Sec. 44); and further states that "any superintendent or other person who interferes with the mine foreman, in the discharge of his duties as described by this Act, shall be deemed guilty of a misdemeanor."

Occult Influence of the Mine Superintendent

Nothwithstanding this provision of the law prohibiting the superintendent from interfering with the mine foreman in respect to the duties of the latter, there can be no doubt of the controlling influence the superintendent exerts by virtue of his superior position. Any foreman well knows that his superintendent has the power to discharge him whenever he may desire, besides being responsible to the management for the showing on the cost-sheet.

In many instances, the foreman realizes that it would be difficult, if not quite impossible, to explain to a superintendent having but a partial knowledge of matters underground, the need for certain work that to his mind is imperative. For this reason, a foreman is liable to allow certain things to go without giving them the attention they should receive. He determines to wait, until conditions appear a little more favorable, preferring to take the chance of increased danger rather than risk his good standing with the superintendent.

Speaking of examinations for certificates, my opinion is that not only should every mine superintendent be certified but he should hold a higher grade of certificate than that required of the foreman. His examination should prove that he has a superior technical education and a longer experience in mines than what is necessary for mine foremen. Having charge of the outside foremen also, the superintendent should prove his knowledge of surface requirements, including all types of machinery and equipment.

While I do not look with favor on the idea of repeated examinations and the limiting of certificates to a period of five years, as has been suggested, I do think that all certificates should be revokable for cause. It seems to me an unnecessary requirement to expect a well posted practical mine official to submit to repeated examinations, at stated periods or intervals.

Mining Men Should Be Students of Mining

In order to secure competent mine officials, which is the greatest factor in the safe operation of a mine, it is my belief that the work must begin with the education of mining men. My idea is that men seeking a position of responsibility in coal mining should become students of mining and should take a course extending over a period of years, a goodly proportion of which should be devoted to practical work underground that would make them familiar with every requirement.

In this regard, I do not refer to the accustomed cramming for examinations that is so common today among candidates for examinations for certificates of competency. Most every intelligent miner who can read and write can prepare himself for answering the questions asked in mine examinations, by studying faithfully for a period of six or eight months. The standard of examinations should be higher, that this sort of cramming could not insure the success of the candidate.

To be frank in the matter, I do not believe in second-class certificates, which make a man eligible for taking charge of a mine not generating gas. Who knows at what time such a mine will generate gas in dangerous quantities. Moreover, most mines are subject, to a greater or less extent, to mine fires that generate explosive or poisonous gases dangerous to life. Every mine official should have a thorough acquaintance with the properties and behavior of these gases.

The Bureau of Mines has shown a deep interest in the education of miners. To that end, they have published numerous pamphlets and bulletins, giving the

miner careful instructions in the use of safety lamps and other appliances employed in the practice of coal mining. Others of these bulletins describe the properties and behavior of mine gases, methods of timbering and many subjects of practical benefit to the miner.

Were it not for the lack of needed appropriations, I feel sure that the Bureau of Mines would adopt some scheme that would bring them in closer touch with students of mining, through the establishment of mining courses, as has already been suggested by Mr. Perdue, in his letter to which I have referred, previously. In that connection, the mine-rescue stations, established by many of the larger coal companies, in different districts, would form good bases from which such educational work could be directed.

As is well known, the prime object of rescue stations is the promotion of safety and what work would be more befitting their purpose than the education of mining men on a broad practical basis? THOMAS ALLEN.

Mount Harris, Colo.

Violation of Mining Laws Chief Cause of Explosions in Mines

Something lacking in the administration of affairs in mining—Not inadequate laws—Personal element responsible for occurrence of mining disasters.

ATTENTION has again been drawn to the frequency of mine disasters during recent months, by C. W. Atkins, writing in *Coal Age*, Feb. 15, p. 302. Mr. Atkins is quite right when he says there is something lacking in our administration of affairs in the operation of mines. However, to my mind, that *something* is not the want of adequate mining laws, as many imagine. Instead, I believe, the cause must be sought in the personal element that is always present and hard to eliminate.

A study of the situation will show that those countries and states that have the best possible mining laws are not exempt from these occurrences. Our mining laws have been drafted to cover most of the dangerous practices in our mines and, with few exceptions, these laws are adequate.

Mining Laws, Rules and Regulations Disregarded

In my opinion, the frequent recurrence of mine explosions is not the result of inadequate legislation. The trouble is that the laws we have are not strictly enforced; and we all realize that a law is of no value, unless it is enforced and every individual worker made to obey the law. A chain is no stronger than its weakest link and every man in the mine is a link in the chain of safety.

As I said before, the personal element is the chief factor in preventing the frequent recurrence of mine disasters. On previous occasions, investigation has shown that incompetence, ignorance, carelessness or disobedience to orders has been the direct cause of the disaster. In the majority of cases, the act has been an open violation of the mining laws or mine rules and regulations.

To one who has had years of experience and traveled much, it is a revelation to observe the manner in which both the laws of the state and the rules and regulations of the mines are disregarded, by mine workers and often winked at by the mine officials. In a few instances we find mines where discipline prevails and violations are suitably punished by the management.

On the other hand, how often do we find that the men holding responsible positions and on whom the lives of hundreds of workers depend, are incompetent. It is this class of worker or type of official that we have most to fear and should strive to eliminate in the operation of our mines.

How Mine Disasters May Be Avoided

Finally, let me add that it is only by the strict enforcement of our mining laws and safety rules and regulations and the careful selection and employment of experienced and competent officials, together with the training of all mine workers and impressing them with a sense of their personal responsibility for their own safety and that of their fellows, that we can hope to avoid disaster.

My answer to the question, "Should firebosses and safety inspectors be employed by the company or by the state or federal government?" is: They should be employed by the company. Employment by the state would not eliminate the personal element and would introduce a new danger, in the opportunity afforded for graft. Much as we regret to say it, there are always some men who can be bought and are willing to take chances for a slight consideration.

So long as we have men employed in the operation of our mines who can be bought, men who are willing and ready to risk their own lives and the lives and safety of their fellow workers and who openly and flagrantly violate the mining laws of the state, in order that they may make a record run and establish a reputation for themselves in the production of cheap coal; so long must we expect disasters to occur.

We all freely admit that, as individual workers, we make many mistakes that endanger ourselves and others working with us; but such mistakes are not made willingly. The all important question, in the attainment of mine safety, is how to avoid such errors and reduce accidents to a minimum. It cannot be done by assuming known risks.

The article entitled "Personal Touch in Management," in the same issue of *Coal Age*, appeals to me as conducive to a reduction of mine accidents. I believe that where officials and employees are brought into closer touch with each other and recognize their mutual relations in the safe operation of the mine, much can be accomplished in the establishment of strict discipline and greater safety will result. GEORGE HALLIDAY.

Carbonado, Wash.

The Company Store, Past and Present

Running the company store on its own merits—Biggest wage earners not always best store customers—Greasing the foreman not a reputable practice.

AT THE time of reading the interesting letter of George Edwards, *Coal Age*, Feb. 15, p. 303, I felt that much could be said in dispute of the idea that the improved status of the company store is to be attributed to the practice of soliciting the mine foreman's aid in securing customers among the miners.

Instead, I would ascribe the observed improvement in the conduct of company stores, among the larger coal companies and most of the smaller concerns, to the present tendency of running these stores on their own merits. My observation is that the average store manager, today, follows the practice of other storekeepers and tries to attract customers by offering fair goods,

at fair prices, and through the courteous treatment of his customers.

In the past, the goods offered in company stores have been of fair quality, but the prices have not been attractive in most instances. Moreover, the treatment accorded would-be customers, by the average store clerk, has been of the "take-it-or-leave-it" type and there has been little display of courtesy on the part of the salesman.

Improved Methods Bring Results

Today, things are quite different in the management of the company store. The manager himself works harder than was the custom in former days and he gets results that were never obtained under the old system. Discourtesy on the part of a salesman, or any lack of attention to the needs of a customer, is met with a sharp rebuke. The fact is realized that the store is in competition with other stores and can command trade only by the proper treatment of its customers.

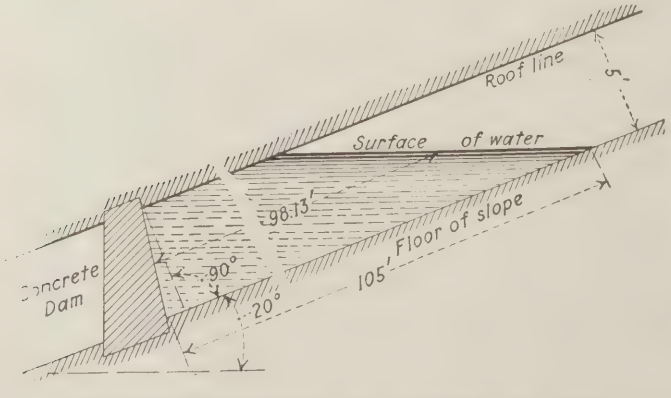
In his letter, Mr. Edwards seems to convey the idea that the improvement observed in the company store of today may be attributed largely to enlisting the mine foreman's interest. It is suggested that an inspection of the payroll shows that many large wage earners are not the best customers of the store, while many who make less money consume practically their entire earnings in store orders before payday.

A little reflection should make known the fact that workmen who draw the biggest pay are those who are willing to accept the hardest tasks performed in the mine. No job is too hard for them and they are always ready to do any work they are asked. They are not seeking, like many others who make less money, the best places and the easiest work.

Under the old system of store management, the payroll was too often made the basis of judging what a man should spend at the company store. Many a mine foreman was led to believe that he would lose his job, unless he made it a part of his business to steer his men in the direction of the store, and the practice has generally proved a financial loss to the company.

The suggestion made in the letter to which I have referred, that good is accomplished by greasing the mine foreman, is bad. Such a practice is not reputable and no foreman could lend himself to it without losing his self-respect and the esteem of his men.

In closing, let me say that where such a practice is in vogue it will result in demoralizing the organization; it would be discriminating in favor of shirkers, to the detriment of good workers. In the end, the foreman would lose his job when the company discovered the financial loss that must inevitably follow the practice. I speak from a personal knowledge of such instances and know many other mining men whose experiences have led to the same conclusion.



New York City. F. C. Cornet.

Inquiries Of General Interest

Concrete Dam Built on Mine Slope

Dam Built in Old Abandoned Slope—Pitching 20 Deg. — Slope Fills with Water — Total Pressure on Dam—Quantity of Water in Slope

KINDLY permit me to present a proposition regarding a concrete dam built in a slope that was long since abandoned. Originally, the slope had a sectional area of 84 sq.ft., being 12 ft. wide and 7 ft. high.

CONCRETE DAM ON SLOPE PITCHING 20 DEG.

For twenty years, a small stream of water has been running down the slope and required to be pumped out of the mine where it accumulated. In order to avoid this expense and to keep the water from running into the lower levels, a dam was built at a chosen point in the slope. In 45 hr. after the dam had been completed and sealed to make it watertight, the slope had filled with water to a distance of 105 ft. up the incline, which had a pitch of 20 deg.

Fearing that the pressure of water would break the dam, we started the pumps to avoid that danger. I should state, here, that, previous to the building of the dam, a squeeze had reduced the size of the slope opening so that it was now only 10 ft. wide and 5 ft. high, giving 60 sq.ft. for the water pressure to act on the dam. We are anxious to learn what quantity of water is in the slope when it has risen to the height mentioned, namely, 105 ft. measured on the floor. Also, what is the total pressure exerted, by the water, on the face of the dam?

Nanticoke, Pa. Albert Turley.

Assuming that the reduced dimensions give the average size of the slope that is now filled with water from the dam to a distance of 105 ft., measured on the floor of the slope and, further, assuming that the face of the dam is in a practically normal position in the seam, as shown in the accompanying figure, the surface of the water will meet the roof, at a distance from the dam, $105 - (5 \div \tan 20 \text{ deg.}) = 105 - (5 \div 0.364) = 105 - 13.74 = 91.26$ feet.

The average length of this prism of water filling the slope is, therefore, $\frac{1}{2}(105 + 91.26) = 98.13$ ft. But, the sectional area of the opening being 50 sq.ft., the volume of water standing in the slope is $50 \times 98.13 = 4{,}906.5$ cu.ft.; or $4{,}906.5 \times 7.48 = 36{,}700$ gal.

The vertical head of water exerted on the center of the face of dam is, $98.13 \times \sin 20 \text{ deg.} = 98.13 \times 0.342 = 33.56$ ft. This head corresponds to a pressure of $33.56 \times 62.5 = 2{,}098$ lb. per sq.ft. Finally, the face of the dam presenting an area of 50 sq.ft., the total pressure is $(50 \times 2{,}098) \div 2{,}000 = 52.45$ tons.

Examination Questions Answered

Miscellaneous Questions

(Answered by Request)

QUESTION—*What effect does a change in the atmospheric conditions at the surface have upon a mine generating explosive gases.*

ANSWER—A sudden fall of barometric pressure is always followed by an outflow of the gas-charged air filling the old abandoned works in the mine. The result is an increase in the gaseous condition of the mine air in the live workings.

QUESTION—*In case of an explosion in a mine whereby the doors and air stoppings are destroyed, what method would you adopt to restore circulation?*

ANSWER—The only possible way of restoring the circulation of air throughout the mine, under these conditions, is to rebuild the doors and stoppings destroyed or make temporary use of canvas as curtains to deflect the air and prevent its being short-circuited at such points. It is assumed that the ventilating fan is still running and capable of supplying the required air. The work of restoring circulation in a mine torn by an explosion is necessarily of a temporary nature when there are men to be rescued, especially if there is no properly equipped rescue corps who can safely penetrate the gas filled roads and workings.

QUESTION—*Are mine fires more likely to occur in one mine than in another and, if so, why?*

ANSWER—Yes, mines where the coal is friable and particularly inflammable, or where the coal contains much sulphur, are more subject to fire from spontaneous combustion occurring in the waste, if necessary precautions are not taken to prevent fine coal being stored in the gob. The presence of gas, also, renders some mines more liable to fires than where there is little or no gas in the seam.

QUESTION—*A shaft 300 ft. deep has an entry turned off at the bottom, 7 ft. high and 10 ft. wide. The shaft is full of water and overflowing. What is the pressure per square inch and the total pressure, in short tons, on the face of the entry?*

ANSWER—Assuming a vertical shaft, the pressure at its foot is $300 \times 0.434 = 130.2$ lb. per sq.in.

Then, if the entry is level the center of pressure at the face of the entry is $300 - \frac{1}{2} \times 7 = 296.5$ ft. vertically below the top of the shaft. This makes the average pressure on the entire face of the entry $296.5 \times 0.434 =$ say 128.7 lb. per sq.in.; and, the sectional area of the entry being $7 \times 10 = 70$ sq.ft., the total pressure on the face of the entry is $(70 \times 128.7 \times 144) \div 2{,}000 = 648.648$ short tons.

QUESTION—*A cross-compound engine has cylinders 16 in. and 24 in. in diameter, respectively; find the piston areas.*

ANSWER—The sectional area of the smaller high-pressure cylinder. 16 in. in diameter, is $0.7854 \times 16^2 = 201$ sq.in.

The sectional area of the larger low-pressure cylinder, 24 in. in diameter, is $0.7854 \times 24^2 = 452.4$ sq.in.

QUESTION—*If the high-pressure cylinder, in this engine, has an initial pressure of 120 lb. per sq.in. find the size of piston rod when the allowable working stress in the rod is 3,500 lb. per sq.in.*

ANSWER—The total pressure on the piston in the high-pressure cylinder of this engine is $120 \times 201 = 24{,}120$ lb. For an allowable stress of 3,500 lb. per sq.in., the sectional area of the piston rod is $24{,}120 \div 3{,}500 = 6.89$ sq.in. The required diameter of the rod is, therefore,

$$d = \sqrt{6.89/0.7854} = \text{say } 3 \text{ in.}$$

QUESTION—*In the low-pressure cylinder of this same engine, the initial pressure is 20 lb. per sq.in., find the number of ¾-in. studs required to hold the cylinder cover in place. The diameter of the ¾-in. studs, at the bottom of the thread, is 0.73 in. and the working stress on the material is 4,000 lb. per sq.in.*

ANSWER—The area of the low-pressure cylinder, as previously found, being 452.4 sq.in., the total pressure on the end of the cylinder is $20 \times 452.4 = 9{,}048$ lb. The sectional area of a single stud, for a diameter 0.73 in. at the bottom of the thread, is $0.7854 \times 0.73^2 = 0.4185$ sq.in. For an allowable stress of 4,000 lb. per sq.in., the safe working strength of a single stud is, $4{,}000 \times 0.4185 = 1{,}674$ lb. The number of studs required to hold the cylinder head is, therefore, $9{,}048 \div 1{,}674 = 5.4$, say 6 studs.

QUESTION—*How many hour's supply would a cylindrical tank 16 ft. in diameter, by 12 ft. in depth, hold for a 500-hp. plant, which uses 34½ lb. of water, per horsepower, per hour? Assume the average load is 75 per cent of the rated capacity of the plant equipment.*

ANSWER—In this case, the average load requires $0.75 \times 500 = 375$ hp.; and the water consumption will be $375 \times 34.5 = 12{,}937.5$ lb., per hour. The cubical contents of a tank 16 ft. in diameter and 12 ft. deep, is $12(0.7854 \times 16^2) = 2{,}412$ cu.ft. The weight of water in this tank when full is then $2{,}412 \times 62.5 = 150{,}750$ lb. Then, assuming a water consumption of 12,937.5 lb., per hour, this tank will be emptied in $150{,}750 \div 12{,}937.5 = 11.65$ hr., or say 11 hr. 39 min.

QUESTION—*If coal occupies 40 cu.ft. per ton, what size of storage bin will be required to carry a three-weeks' supply of coal for a plant where the water consumption is 12,937.5 lb., per hr.? Assume a pound of coal evaporates 5 lb. of water; and state what weight of coal will be required in storage.*

ANSWER—A water consumption of 12,937.5 lb., per hr. will require an assumed coal consumption, in this case, $12{,}937.5 \div 5 = 2{,}587.5$ lb., per hr. The coal consumed in an 8-hr. shift will then be $(8 \times 2{,}587.5) \div 2{,}000 = 10.35$ tons. Now, making due allowance for maintaining fires during idle hours, Sundays and night-shifts, the average consumption of coal may be assumed as, say 12 tons, per working day. A three-weeks' coal supply, on this basis, will be $3 \times 6 \times 12 = 216$ tons, which is the required capacity of the storage bins. Allowing 40 cu.ft. per ton, the cubic capacity of the bins will be $40 \times 216 = 8{,}640$ cu.ft. Assuming a length of 100 ft. for the bins, and a width of 10 ft., the average depth of coal in the bins will be 8.64 ft.

QUESTION—*How many cubic feet of air should be mixed with one cubic foot of firedamp to render it harmless?*

ANSWER—Assuming the firedamp mixture at its most explosive point and no dust present, 1 cu.ft. of the mixture contains 0.0946 cu.ft. of methane. Then, allowing two per cent of gas is harmless, under ordinary conditions, the total volume of gas and air is $0.0946 \div 0.02 = 4.73$ cu.ft., and the volume of air to be added is, therefore, $4.73 - 1 = 3.73$ cu.ft.

Export Coal Trade Still Shows Promise Despite Decline in Inquiries

Foreign inquiries and offers for our coal have decreased somewhat in the past month, according to Federal Fuel Distributor F. R. Wadleigh. The decrease is attributed partly to the expectations of an early settlement of the Ruhr situation, partly to the increase in prices of our coal at tidewater, together with the rise in ocean freight rates. Unwillingness on the part of our exporters to give the credit asked for by foreign buyers undoubtedly has prevented a number of sales.

Additional charters are being closed and the prevalent feeling seems to be that with a decline in ocean freight rates in the last week of April and a decrease in prices of coal from the high level of March, our coal exporters will be able to obtain considerable foreign business for the next few months. In fact, some of the contracts already closed cover deliveries over from four to six months and even longer.

Overseas exports of bituminous coal (including the West Indies) for January were 79,874 gross tons, decreasing to 75,204 tons in February and reaching 270,711 tons in March. Coke exports in the same months were 11,399 tons, 12,026 tons and 35,309 tons. The bulk of the coke has gone to France, while Italy, Germany and the Netherlands have taken the greater part of the coal.

From Feb. 20 to March 12, 52 steamships had been closed for the transatlantic coal and coke trade. From the latter date to April 30 the local number of charters announced as closed was 101 for coal and 80 for coke. There are always some charters not made public, so that the number given is slightly less than the total number chartered.

Inquiries for coke are not so numerous or urgent and there is a considerable accumulation waiting to be loaded into ships at tidewater; embargoes on coke for export are in effect at both Baltimore and Philadelphia and the permit system is being used by the railroads in moving it.

Commenting on the Ruhr situation Mr. Wadleigh in his statement of May 10 says:

"While it is impossible to obtain any actual figures of the Ruhr production for the past four months, indications point to a shortage of about twenty million tons during that period, as compared with the last four months of 1922. This shortage has, of course, affected all of the western European countries, but especially those where coals for making coke are imported—viz., France, Belgium, Italy, Netherlands—increasing the demand for British coking and gas coals, and causing a rise in f.o.b. prices of the latter from 25s. to 37s. 6d. for the best Durham gas and coking coals.

"The shortage in shipments of German coke to France, which totaled 4,303,324 metric tons in 1922, has also increased the general demand for coke. In January, 1923, there were 407,663 tons of coke imported by France; in February this had fallen to 164,577 tons, of which only 84,605 came from Germany. Coke production in the Ruhr field is reported as about 40 per cent of normal; coal production about 30 per cent."

A number of American coal exporters gave their views to Mr. Wadleigh, who quotes from them as follows:

"A number of inquiries are being received from South America," one exporter said, "and I am of the opinion that the South American trade will be good during the present year, as I believe England will take a large portion of the European business on account of the short haul and will be content to let the South America business go, expecting to regain it at a later date when needed. On account of the present European situation, I do not think there is any doubt but what the export business in coal will be good during the entire year, although I do not believe it will be sufficient to cause any actual shortage in this country, particularly if there is any marked improvement in the railroad transportation in this country, which there will probably be. The demand from Europe, however, has advanced the Cardiff and other British prices to such an extent that we are beginning to get inquiries and business from South America."

"My opinion is that the present situation, if cared for properly by the American exporter and handled with even ordinary intelligence," another shipper stated, "will enable us all to develop and maintain a sane and safe business in the future. The miserable interloper who injected himself in 1920, however, must be kept out or he will do again what he did then—practically destroy the confidence of the foreign buyer in the American coal exporter."

Stability Attained by Operators Upset by Snowbirds and Adverse Strike Settlement

The Bituminous Operators' Special Committee issued a statement on stabilization of the industry May 15, as follows:

"Before the war many large companies, and in some cases entire bituminous coal-mining fields, had accomplished a substantial degree of stability in the industry. There never was a real shortage of bituminous coal from the beginning of the century.

"With the war, and the unprecedented demand for fuel, prices went so high that the 'snowbird' mines were able to open and produce coal. The effect of this is always bad, as these mines demand from the railroads, cars which ordinarily would be used to handle the output of those mines which operate all the time, whether the market is high or low.

"The effect of this dilution of railroad cars is to limit output through the transportation factor. It is easily seen that a locomotive can operate far more efficiently leaving a train of cars at a mine, than running up and down the line leaving a car or two here, another car there, for many miles, then collecting them again. The fact that the railroads are forced to deliver cars to the 'snowbird' mines cuts down supply to regular mines, limiting their output.

"A further interference with the stability of the coal industry is the fact that the strike of last year, lasting five months and causing suffering and death, was settled adversely to the interests of the public. This settlement forced the inflated war wage scale for common labor in the mines to continue. This high wage naturally attracts many unneeded men from other industries, as no skill or training is required for the work for which union miners have insisted upon being paid $7.50 a day. This overmanning of the industry has now reached the point where there are 200,000 extra men being supported by the public in the coal-mining industry, as is recognized by the U. S. Coal Commission.

"While the strike was on, President Harding recognized that the nation was in the grip of this labor monopoly. He gave voice to this thought before Congress in an address, declaring that the country was 'at the mercy' of the United Mine Workers.

"With the present tremendously expanded supply of mine labor, naturally the miners work only part time in order to make a living. They are enabled to do this because of the high wages they receive. At the same time, it would be unsound economically to fix mine wages on the supposition that the miners are going to work on part time. Putting wages at the proper level would, through the operation of economic laws, rid the industry of this surplus of 200,000 men, and help materially to stabilize the industry. The present tendency of the miners is to work only part time, regardless of the working time of the mines in which they are employed.

"The United Mine Workers of America naturally is not averse to keeping unneeded men in its ranks. Through the 'check-off' system it collects dues from its members which now aggregate $15,000,000 a year. Cutting down the number of miners to those needed to produce the nation's coal supply would lop off the unneeded members of the United Mine Workers, and consequently cut down its enormous income from membership dues.

"In the last analysis, the leaders of the United Mine Workers control 60 per cent of the output of coal. Agreements with this organization have proved of little value, as they have been broken at will on many occasions, the list of which is a long and disgraceful one."

Price of Coal to Industry Governed by Shortages Caused by Labor Unrest, Says Bradley

The Natural Resources Group of the U. S. Chamber of Commerce gave over Wednesday afternoon to the coal industry at its 11th annual meeting in New York last week. The Green Room of the Waldorf was crowded, more by those wanting to learn about the coal situation than by coal men. J. D. A. Morrow was scheduled to speak but was unable to attend. J. G. Bradley opened the speaking program after the luncheon. His address, "Labor and Its Effect on the Cost of Industrial Coal," in abstract follows. An abstract of the talk of George Cushing, the second and last speaker, was carried in *Coal Age* last week.

"Throughout this discussion it should be understood that it is my opinion that the price of coal to the consuming industries has been governed rather through the creation of shortages with attendant speculation, the shortages being brought about by interference with the distribution of coal over which the operators had no control rather than through inherent defects in the industry itself," said Mr. Bradley. "Absentee labor control on the part of ambitious union leaders of both the miners and railroad operatives has been the chief contributing influence in the creation of these shortages, as an examination of the records of the U. S. Geological Survey and the American Railway Association will show.

"In considering labor and its effect on the cost of industrial coal, the whole general question of coal-field labor comes into review, both what it is paid directly and what it receives indirectly, as well as its peculiar efficiencies and inefficiencies, its privileges and immunities, all of which have various bearings upon the cost of the coal before it can be shipped to market. It should be understood that most coal-mine labor is housed in communities constructed and maintained by the operating company. It is the custom in the coal fields to lease the company houses at the monthly rental of about $2 a room and it may be generally stated that the operatives pay about $15 per month for rent, light, heat, fuel, doctor service for the entire family and insurance for themselves, which reduces their cost of living far below that of any other class of wage earners of which we have record.

"While the eight-hour day is the standard throughout the coal fields, as a rule only the day men work for the full eight hours and those constitute but 40 per cent of the employees at the ordinary bituminous-coal operation; the miners themselves, being paid by the ton, are free to quit work as soon as they have mined the number of tons which will bring their earnings up to an amount which is satisfactory to them. It is, therefore, an occupation with special privileges.

"As an occupation coal mining has its compensations and it is rarely that a man engaged in it leaves it for other pursuits. The operators have been charged with maintaining in the industry more men than are necessary to carry it on, but this is something which they could not do by force and if there is an oversupply of mine labor it is because of the attractions offered to the workers by the industry itself, and in the union districts to the encouragement held out by the labor leaders for the realization of a full-time wage for part-time work.

"According to the preliminary report of the U. S. Coal Commission there were employed in the bituminous-coal industry 663,000 men, or more than 60 per cent of all the employees engaged in all kinds of mining in the United States, and of these 663,000 men, about 500,000 are claimed as members by the United Mine Workers of America. The total number of wage earners of the country as shown by the last available census figures is about 9,000,000. It therefore appears that about 7 per cent of the wage earners of the country are engaged in the production of bituminous coal. The production per man in 1921 was, as shown by the U. S. Coal Commission's figures, about 650 tons each.

"Only for short periods since 1918 has the price of coal to industry been closely related to the cost of production. It has been controlled by its availability in the market, which has depended upon and been influenced by various interruptions to the process of distribution brought about by strikes both within the coal industry itself and on the railroads. In other words, it has been the interferences with the orderly conduct of the business which has made the market price, rather than the cost of production itself.

"There has been a growing tendency in both union and non-union mines toward absenteeism on the part of the well-paid workers. Since the pay increase granted in 1920 the thriftless men have occupied positions in which their failure to report for duty has thrown others out of work; they have both added to the cost of coal by reducing the mine's production and done injury to numbers of the fellow workers and their families. This may be illustrated by the case of a cutting-machine runner whose failure to report for duty causes idleness of a dozen leaders the following day. About the mines there are many such key positions, and if one has not had practical experience it is hard to believe that such cases should occur as frequently as they do. In union operations it is a well-known fact that public opinion among the workers prevents the ambitious individual from doing more than the accepted average on the old and fallacious theory that to do more would take work away from someone else, losing sight of the fact that anything which tends to increase production and lower the cost thereof tends toward the reduction of the cost of living generally and means a greater purchasing power for the wage earner himself.

Labor Most Important Item of Cost

"Emphasis is put on the need of production in volume to decrease costs. The increase in productive capacity which we have had has been too widely distributed. Economically, conditions would be happier if the production were better concentrated and the mining units were fewer and larger. If the interferences which perpetuate speculative conditions in the coal markets could be removed, unrestricted competition would soon bring this about.

"The most important single factor of cost is the labor item with its 68 per cent of the whole. In conjunction with wise and skillful management and the progressive development of mechanical mining, labor can play a principal part in cutting fuel cost in the future. It was this combination in the non-union coal fields of the country which started the wheels of industry turning in the early part of 1922. Cheap power is dependent upon cheap fuel and cheap power is the talisman of industrial supremacy.

"The 8,400,000 wage earners of the country who are not engaged in mining coal cannot afford to protect the coal miner in the enjoyment of a special wage; they cannot wisely grant him a subsidy which will keep him in an industry at which he proposes to work but six hours a day five days a week. If they are inveigled into such a course by arguments of sentimentality or threats which arouse their fears they will find themselves supporting a policy and perpetuating an economic condition which will take from their children the wonderful opportunities for work, development and individual liberty which they inherited from their fathers. They are but paving the way to a future of socialistic indolence and misery in which the only persons with full stomachs will be those who succeed in ingratiating themselves with the little ring of astute political minds who can stay in control prior to the period of final chaos.

"The time will come again when the market price of coal will be based upon the cost of production, and then the industrial manager will have brought home his interest in the proper solution of the mine-labor problem, and he probably will be surprised to find how much the giant of irresponsible unionism has grown, and shocked to learn that he, the industrial manager, has supplied the wherewithal to make him grow."

Unionization Necessary for Stabilization, Say Union Officials

Union recognition and joint agreements provide the only way through which the coal industry can be stabilized, and stability is essential to the success of the industry, the United Mine Workers of America declares in a communication submitting "certain constructive suggestions concerning the coal industry" to the U. S. Coal Commission.

The communication consists of statements by Philip Murray, International vice-president of the union, and William Green, secretary-treasurer of the organization.

Mr. Murray says the U. S. Coal Commission by an aggressive, fearless attitude can compose all differences which exist in the unorganized coal-mining sections of the country and can further provide a peaceful and prosperous basis for collective bargaining which will govern the future procedure of the industry in those fields.

The only practical way in which this can be done, Mr. Murray contends, is to bring about for the non-union mining territory of this country working agreements which will safeguard properly the fundamental rights of mine workers and mine operators, protect the public and provide a just and reasonable basis for working relations and conditions. The safeguards which are essential to regularity of production and of peace and tranquility are:

"The guarantee of freedom of speech, freedom of assembly, freedom of movement.

"The right of all workers to organize and bargain collectively through representatives of their own choosing.

"The protection of mine workers against discrimination because of membership in the United Mine Workers of America or any other labor organization.

"The assurance that democratic institutions, such as the United Mine Workers of America, will not be subordinated to industrial control by the practice of the non-union coal operators in paying and controlling deputy sheriffs and constables or by employing private guards instead of using the services of distinterested, conscientious peace officers."

Admitting that the union does seek to organize the entire coal industry, Mr. Murray says its sole purpose is to seek uniformity of wages and working conditions and regularity and continuity of employment, and thereby to bargain collectively with the operators on terms approaching equality. Contending that all coal operators, including those in the non-union fields are organized, through membership in the National Coal Association, Mr. Murray, adds: "In all fairness, it should be possible for all the miners of the country, including those in the non-union fields, to be united in their national organization so that they may meet the maximum economic strength of the operators with the maximum economic strength of the mine workers."

At the same time Mr. Murray says: "We do not seek to control the coal industry, but we do demand a voice in its control. Advocates of the open-shop movement have taken as their slogan 'Those who pay should have the say.' Today the whole world knows that might does not make right but that right makes might, and we believe we are fundamentally and eternally right."

Mr. Murray declares the miners' organization stands for industrial peace, the stabilizing of conditions of employment and for the continuity and acceleration of production, while the non-union operators have nothing to offer except arbitrary action and industrial autocracy. The fruits of their policy, the statement says, are industrial and civil warfare.

Mr. Green's statement deals with collective bargaining and union recognition, and declares there can be no recognition of the principle of collective bargaining without a corresponding recognition of the right of the workers to organize into trade unions. To deny the workers the right to organize is nothing more, Mr. Green declares, than improper interference with the exercise of an inherent right and normal activities of a free people.

Notwithstanding the criticism emanating from some groups of people because of the coal strike of 1922, Mr. Green says there were only two failures to negotiate wage scales resulting in national suspensions during a period of twenty-three years in the anthracite and about thirty years in the bituminous-coal fields.

This record becomes the more remarkable, he says, when it is considered that these wage scales were negotiated through voluntary action on the part of coal operators and miners. "Joint wage agreements in effect for fixed periods of time between coal operators and miners serve to stabilize the industry and to guarantee an adequate coal supply. No interruption of mining operations because of a strike can take place during the life of the joint agreement. Such agreement, however, can only be successful through collective bargaining based upon union recognition.

"In coal fields where the miners are unorganized there can be no guarantee against strikes. The men employed in these sections are not parties to an agreement, are under no obligations to continue at work. Consequently they are free to cease work at any time. Especially is this true when the men employed in non-union territory become dissatisfied with the wages and conditions of employment arbitrarily fixed by their employer, and their desire to organize and for union recognition becomes strong."

As in every industry, Mr. Green says there are in the mining industry good and bad employers, none of which should have the authority arbitrarily to fix the wages and working conditions which their employees must accept. "Those who work and serve in industry are as essential to success as those who operate and manage the industry. Each has rights which the other should respect. Neither should become a dictator, because that would be autocracy in industry, something which is repugnant to the American sense of fair play."

Replying to the charge that may be made by those opposed to union recognition and collective bargaining, that if the mine workers were completely organized they would strike and paralyze the industries of the nation at will, Mr. Green said: "There could be no strike except at the termination of a contract period and then only in the event of a failure to agree upon a new wage agreement. The moral responsibility of the operators and miners would be so great and solemn that they could not, except in extreme emergency, refuse to agree upon the terms and conditions of a fair and reasonable wage scale."

Appellate Court Modifies McClintic Order Restraining Payment of Check-Off

The U. S. Circuit Court of Appeals at Richmond handed down a decision May 7 modifying the injunction of Judge George W. McClintic of the U. S. District Court for the southern district of West Virginia to the extent of eliminating that feature prohibiting the payment of check-off funds to the United Mines Workers. Judge McClintic's order had not only restrained the payment of the check-off but also enjoined the union from threatening or interfering or attempting to interfere in any manner whatsoever with employees of the Carbon Fuel Co. and 22 other mining companies in the Kanawha region.

In entering a modifying order, the appellate court to a great extent followed its action in the Borderland Coal Co. case. The one exception was as to the check-off, which the higher court permits to remain in force. Although the union is permitted to collect the funds derived from the check-off, the organization is not permitted to give or remit such money to striking miners who may be occupying houses on the property of the Carbon Fuel Co. and other plaintiff companies with a view to rendering assistance to such occupants so as to have them retain such occupancy in violation of the law. The appellate court continues to enjoin the United Mine Workers from aiding or abetting any person or persons to occupy or hold without rights any property of the plaintiffs by sending money or other assistance to be used by such persons in furtherance of such unlawful occupancy or holding.

Pending adjudication of the case on its merits in the district court, the injunction order of the appellate court is to remain in full force and effect.

THE OLD-FASHIONED religious revival depended on faith. And so does a business revival.—*Fresno Republican.*

Commission Probes Deeply Into Valuations, Royalties And Effect of Unionism on Productivity

By Paul Wooton
Washington Correspondent of *Coal Age*

That the President's Coal Commission is making more searching investigations than has been generally realized into the important matters of degradation of coal, productivity of labor under union and non-union conditions, establishment of fair valuations of mining properties, and of the royalty charges on coal lands was revealed on May 11 when Chairman Hammond, Governor Marshall, Dr. Devine, Dr. Smith and Mr. Howell, of the commission, discussed their work at the conference with representatives of the press.

It was the quality of anthracite rather than its price which gave rise to most of the complaints of last winter, Dr. Devine stated. He said the commission is anxious to receive suggestions as to the best procedure which will insure the receipt by the public of the quality of coal for which they are paying. He pointed out that some guarantee as to coal quality is in the interest of producers and dealers, as well as the ultimate consumer. The matter was discussed with the anthracite operators when they appeared before the commission. The operators expressed the opinion that there would be no difficulties arising from the quality of coal in normal times. Apparently, however, the commission expects to go deeply into the subject and is anxious to have opinion as to the advisability of leaving quality-control to the industry itself or whether government inspection is justified.

The anthracite operators seemed to have impressed the commission with their suggestion that prices to the ultimate consumer could be reduced materially were people to be less fastidious in their demand for "styles" of coal. They told the commission that there is no sound economic reason for the preparation of so many grades of anthracite. If the public would consent to a reduction of grades and will burn two grades together it would be possible for them to have more heat at a much less price, the commission was told. Governor Marshall advanced the opinion that the average householder would benefit were he to take a correspondence course in "Being One's Own Fireman." Dr. Smith admitted that some consumers are "more fussy than sensible."

Dr. Devine was positive in an assertion that the commission would have highly accurate information as to the productivity of labor under union and non-union conditions. This phase of the commission's inquiry is being conducted very carefully in the hope that the uncertainty will be removed from this much mooted point. Figures in that particular are being taken under a variety of working conditions.

In order to calculate the actual earnings of coal producers, accurate ideas as to property values must be available. Methods which are to be followed in the evaluation of coal mines are to be suggested by a committee of engineers which has consented to serve the commission in an advisory capacity. The personnel of the committee is as follows: R. V. Norris, Wilkes-Barre; H. M. Chance, Philadelphia; S. A. Taylor, Pittsburgh; J. H. Allport, Barnesboro, Pa., and James R. Finlay, of New York. This committee will serve the commission without compensation. These men were invited by the commission to do this work because of their long experience in the work of valuing mining properties. Several members of the committee have taken prominent parts in tax valuation work of various states.

Royalty charges were discussed with the anthracite operators and with Senator Pepper. In that connection, Governor Marshall announced that one of the best lawyers in Pennsylvania had been retained by the commission to advise as to the possibilities of fixing or limiting royalty charges. The commission is trying to ascertain to what extent the high royalties on the Girard holdings set the pace for royalty rates on other lands. Senator Pepper's statements in regard to royalties were general in character.

The anthracite operators committed themselves thoroughly to the policy of selling coal to any group of ultimate consumers willing to buy as much as a full carload. While this was not possible last winter, owing to the workings of the allocation plan, set up to insure equality in the distribution of the limited supply, the operators assured the commission that anthracite would be sold in carload units and shipped to any point where side-track facilities are available. This led several of the members of the commission to suggest that the way is open for any householder who is dissatisfied with his dealers' price to club together with three or four of his neighbors and purchase a carload of coal direct. One instance was cited where that plan had resulted in a saving of $6 a ton to the ultimate consumer.

In response to an inquiry from the Retail Coal Merchants' Association, the commission stated that it is committed to the advisability of the universal adoption of the short ton as the unit to be used in the coal trade.

Chairman Hammond stated that the discussion with the anthracite operators had been extended and had covered many of the important phases of the situation, but that the question of the wage agreement had not been broached as yet. He reiterated that the commission is particularly anxious to expedite these negotiations, so as to remove as quickly as possible the uncertainty which will surround anthracite until the new agreement is signed. He stated that the commission expects to confer with John L. Lewis within a few days and that further conferences with the anthracite operators will be held. No conclusions have been reached by the commission and none will be attempted until the representatives of the miners have been heard on each point in the presentation made by the anthracite operators.

The published article purporting to be an outline of the commission's anthracite report was described as fanciful fluff. It was stated positively that no draft of this report has been made and that the commission has no idea of attempting to formulate its report until it has heard finally from all concerned.

Merger of Northwestern Docks Begins

The Pittsburgh Coal Co. has "purchased a substantial interest" in the Milwaukee-Western Fuel Co., one of the largest dock interests on the upper Great Lakes. This announcement, together with the word that Alex B. Uhrig, president and director of the Milwaukee-Western, had resigned, was issued May 10 after a meeting of the directors of that company. This is the first definite news about the various dock mergers that have been rumored for weeks. It is now confidently expected by coal men that within a short time another great Northwest distributor will announce the absorption of several smaller dock companies.

Joseph W. Simpson, for years connected with the Milwaukee-Western, has been named to succeed Mr. Uhrig as president and will have direct charge of the business under the new régime. Mr. Uhrig declined to discuss his future plans.

The company operates ten dockyards in Milwaukee harbor, all of which are equipped with the most improved coal-handling machinery. From 2,000,000 to 3,000,000 tons of coal were received by lake annually by the company. The company also is interested in a fleet of steel steamers which are engaged in the coal and grain carrying trade.

Peter Reiss, of Sheboygan, Wis., head of the C. Reiss Coal Co., another of the principal Northwestern dock concerns, denies that his company is combined in the Pittsburgh-Milwaukee-Western consolidation. He had a hand in effecting the combine, but he was acting only as a director of the Pittsburgh Coal Co., he said.

In Kansas Everybody Is Willing for the Other Fellow to Remedy Coal Troubles

Manifestation of willingness for the other fellow to do something to put life in the Kansas coal market was the outstanding feature of the conference of operators, dealers, miners and railway officials in Topeka, May 10. Representatives of the miners expressed eagerness to support any move other than a reduction of wages. Retailers were willing to sponsor anything but a shaving of their own profits. The railroads favored anything but a reduction of freight rates. Operators declared they were producing coal at a loss right now. And E. T. Hackney, representing the Governor, who called the conference, had no reply to the suggestion of C. P. A. Clough, president of the Jackson-Walker Coal & Mining Co., that the state burn coal instead of oil in state institutions. The only point on which all were in accord was that the public should be encouraged to store its winter coal during the summer.

The conference was called by Governor Davis following his receipt of the report of Mr. Hackney, appointed by the Governor to investigate conditions in the southeastern Kansas field. Mr. Hackney found many mines closed, and others operating only one or two days a week. He found between 8,000 and 10,000 miners out of work.

His suggestions were passed on to the men at the Topeka conference, and, as has been indicated, each group was heartily in favor of the others putting them into effect. But Mr. Hackney had no suggestion for correcting the one thing above all others that is injuring the Kansas coal field—oil competition. Operators insist that lower freight rates and wage reductions alone can make it possible for them to lower prices to meet it.

Wage contracts have almost a year to run, so there is no possibility of immediate relief in that direction. But an attempt will be made to obtain lower freight rates from the Kansas field to the Missouri River at the hearing before the Interstate Commerce Commission in Kansas City starting May 17.

Strike Threat for Nationalization of Coal Mines Looms, Says Cornwell

John J. Cornwell, former Governor of West Virginia, told the members of the National Association of Manufacturers, in convention in New York City on May 16, that the coal miners are contemplating a nationalization of the mines, but that it was a question whether they would make the effort at the expiration of their present contract or wait until later.

"There is one thing of which I do feel certain," said Mr. Cornwell, "however, and to my mind it is just as sure as anything in the future can be, and that is that sooner or later, and I do not think it is very long off, the miners' organization will make an issue of the 'nationalization' of the coal mines and fight it out with a strike on that line.

"It is the basic demand of the United Mine Workers' organization and the officers are intent upon pressing it at the proper moment. There is a lull now, while the Government Fact Finding Commission makes its investigation, but if that commission's report is not satisfactory to them, and it will not be satisfactory unless it flatly advocates 'nationalization' of the mines, then the storm will break again and the agitation begin.

"If the United Mine Workers and those who agree with them—in other words, other organized labor groups—become powerful enough to force Congress to pass a bill 'nationalizing' the mines, they will also be powerful enough to fix the rates of pay as high as they like and to make the working conditions whatever they care to have them. And if, at any time, Congress should refuse or fail to enact the legislation demanded, it goes without saying that they would strike as quickly under government ownership and control as under private ownership and operation. So, there would be no relief coming from government ownership or 'nationalization' of the coal mines.

"It may be that the Coal Commission created by authority of Congress and now investigating all the phases of this question can find some method by which the industry can be stabilized and the situation improved, but, while I am not pessimistic about it, I am not very hopeful that it will be able to do so. I am rather inclined to the view that the large consumers, as a whole, might aid in stabilization were they willing and able to store a larger quantity of coal than they ordinarily do and thus stretch the production of coal over the entire year rather than have the demand come intermittently and sometimes fiercely, causing a great depression in the industry at certain seasons and unduly high prices at others, things which happen almost every year."

J. H. Sanford Disposes of $5,000,000 Coal Properties in Pittsburgh District

Bituminous coal properties in Washington and Allegheny counties, Pennsylvania, with an actual annual production of 3,000,000 tons, dock and yard sites and undeveloped or virgin coal lands in the Pittsburgh district are involved in the sale just completed by J. H. Sanford, of Pittsburgh, of his interests in the Carnegie Coal Co. and subsidiary corporations to John A. Bell, president of the Carnegie Trust Co. Five million dollars is said to be the price paid by Mr. Bell.

J. H. SANFORD

The following corporations and properties are included: the J. H. Sanford Coal Co., with mines at Racoon Station; the Carnegie Coal Co., with seven mines, at Oakdale, McDonald, Primrose, Racoon, Burgettstown, Atlasburg and Cedar Grove; the Pittsburgh & Lehigh Dock Co., with docks at Duluth, Minn.; the Carnegie Dock & Steel Co., operating at the Superior Dock, Superior, Wis.; the Chartiers Mining Co., with 44 acres of yard sites at Duluth, St. Paul and Minneapolis, Minn., and 1,500 acres of virgin coal lands, and the Carnegie Supply Co., with stores in Allegheny and Washington counties, Pennsylvania.

With this sale Mr. Sanford practically retires from a field in which he has been a dominating factor in the Pittsburgh district for over forty years, though he still retains his interest in the Chartiers Creek Coal Co., of which he is vice-president and which produces 500,000 tons annually of gas coal from operations near Cannonsburg in Washington County, Pennsylvania.

Under the name of the Jesse H. Sanford Co. he bought his first mine, the Leesdale, just above Carnegie in Allegheny County, Pennsylvania, at the age of twenty-eight. In 1899 his holdings had been increased to three mines, which were sold to the Pittsburgh Coal Co. The following year he bought 1,000 acres of coal land at Frederick, Pa., with Brown & Co., and at the same time organized the Carnegie Coal Co. with his father-in-law, the late R. P. Burgan. The latter sold his one-third interest a few years later to Mr. Bell, who now takes entire control of this corporation.

Northwest Dock Rate Decision, Expected July 1, May Bring Long List of New Complaints

It is now confidently expected by most interested parties that the Interstate Commerce Commission will return its decision in the Northwest dock rate cases, or at least the principal ones, by July 1. The hearing in Minneapolis on the dock operators' complaint of discriminatory rate relations ended May 8. Oral argument in Washington June 14 winds up the public action and leaves the commission free to arrive at its conclusion as soon thereafter as possible. It is prophesied by many midwesterners that the decision will be against any disturbance of the present rate schedules between the docks and inland Northwestern points and between Illinois and the same territory. However, if the commission orders southern Illinois rates changed, inevitably there will ensue a filing of many new complaints to secure new differentials between Illinois groups. Much tentative preparation is now being made.

The hearing ended Tuesday, May 8 with very little that was sensational on any hand. There was a little chance for grand stand play in the fact that the appeal for adjustment might have been for a reduction of lake-rail rates. This would have received considerable popular acclaim. Instead the situation was outlined by the docks as discriminatory and relief asked, the form to be left to the decision of the commission. It may be assumed that any relief based upon an increase in the rates from the all-rail fields would be received with vigorous and emphatic opposition from the general public in the Northwest as well as from public officials and politicians.

Various representatives of the Twin City coal dealers entered opposition against any move that would deprive them of the favorable all-rail rates now enjoyed and predicted that any adjustment which increased the all-rail rates would result in higher prices to the public.

A. J. Holmes, of the Holmes & Hallowell Co., stated that in North Dakota last winter 71 per cent of the fuel consumed was lignite, due to the high price of soft coal from Illinois and Indiana. A. J. Eckstrom, of the Flour City Fuel & Transfer Co., Minneapolis, testified in opposition to any increase in rates, stating that 75 per cent of his company's business was in Illinois or Indiana coal; 20 per cent dock coal and 5 per cent all-rail Eastern coal.

The railroads were generally opposed to any adjustment that involved any reduction in freight rates, on the ground of loss of revenue to themselves. Some of them did not indicate why they were so staunch for sustaining the low rates from the all-rail fields made by connecting lines, as against a lower rate from the docks, wherein they would have the entire revenue to themselves. They testified that any increase of the rates from Indiana and Illinois to the Northwest would result in forcing coal from those fields off the market in this territory.

A representative of the Minnesota Railroad and Warehouse Commission testified that any adjustment involving an increase of any rates now existing would be opposed as being bound to increase the cost to the consumer, and would also discourage industry. This position was supported by traffic experts from the St. Paul Association and from the Minneapolis Traffic Association.

Cross-examination of the carrier representatives brought out the admissions that the all-rail rates were favorable as compared with rates on other commodities, but they insisted that the railroads could not stand any loss of revenue.

Judge Berkey Permanently Enjoins Union In Somerset County

Judge John A. Berkey, in the Somerset County Court on Friday, May 11, after an all day hearing, made the injunction sought by the Quemahoning Creek Coal Co., operating mines at Harrison, Somerset County, Pa., permanent against the officers and members of the United Mine Workers, prohibiting the union from picketing and otherwise interfering with the company's operations.

The coal company has 200 men employed at Harrison, with whom it has a contract that they will not join the union during a fixed period. A temporary injunction was granted previously and the final hearing brought out important testimony to the effect that the union held meetings weekly in the vicinity of the mine; that the union organizers accosted non-union miners, appealing to them to "quit scabbing" and "join the strike." The defendants also were charged with contempt of the court's order of last year enjoining the congregating of strikers around mining property.

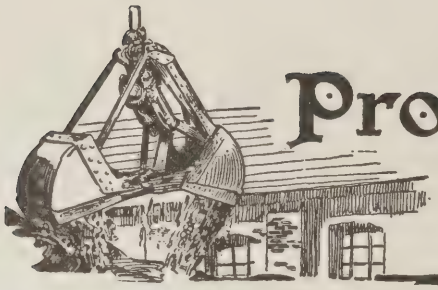
Reading Company Files Third Modified Plan Of Segregation; Government Objects

The Reading Company on May 10 filed a third modified plan of segregation with the U. S. District Court of Philadelphia providing an increase in the interest rate on the bonds to be issued by the segregated companies. The plan provides for the payment of 5 per cent interest on approximately $31,000,000 of new bonds on the company's property, instead of 4 per cent, and 4½ per cent interest on approximately $63,000,000 bonds to be issued by the Reading Company, instead of interest of 4 per cent, as heretofore provided. The new mortgage on the railroad will be known as an open-end mortgage, and the plan provides for the exchange of general mortgage bonds outstanding for one bond of Reading Company at 4½ per cent and one of the coal company at 5 per cent.

The coal bonds are to mature in fifty years and the railroad bonds will mature in seventy-four years.

The Attorney General has filed a brief in the Reading segregation case in which objection is made to certain provisions of the third modified plan. The government objects to increasing interest rate on the bonds on the ground that such additional charges would result in higher prices for coal. The government asks that the District Court determine the amount of compensation to be paid in cash.

Fuel Association Meeting Program Complete



The program of the fifteenth annual convention of the International Railway Fuel Association, at Cleveland, Ohio, May 21-24, embraces a large number of speakers, who will discuss topics of pressing interest. T. K. Maher will welcome the visitors on behalf of the coal operators. Among those who will make addresses are Julius Kruttschnitt, George H. Cushing, whose subject will be "Classification of Coals"; C. E. Maurer, president Glens Run Coal Co.; H. M. Griggs, manager Ore & Coal Exchange, Cleveland, "Lake Coal Handling"; and C. S. Beyer, Jr., consulting engineer, Labor Bureau, Inc., "Incentives for Promoting Fuel Economy."

The local committee in charge of entertainment has announced a program of entertainment as follows:

Monday, May 21, afternoon, theater party for ladies at Keith's Palace theater; evening, Get-together reception at 7:30. Moving pictures of oil production and usage will be shown at 8:30 by courtesy of the Southern Pacific Co., followed by a dance.

Tuesday, May 22, afternoon, educational trip to American Steel & Wire Co.'s Newburg and Cuyahoga plants, or to coal- and ore-handling docks. Automobiles will be provided by Cleveland coal operators. In the evening the annual dinner and dance will be held.

Wednesday, May 23, noon, luncheon for ladies at Cleveland Art Museum, followed by a personally conducted tour of the museum and drive around Cleveland; evening, entertainment given by Cleveland coal operators.

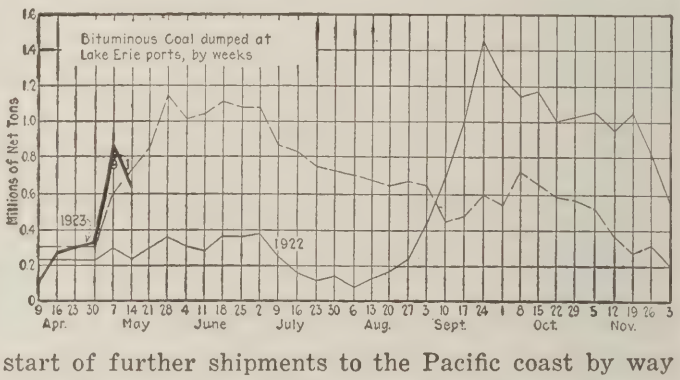
Production and the Market

Weekly Review

Prices of soft coal have advanced a trifle from last week. Buying continues quiet but inquiries increased and there was an apparent attempt to buy at present prices for future delivery which is taken by operators and shippers as an inclination on the part of consumers to guard against future transportation difficulties.

Bituminous-coal output continues above 10,000,000 tons per week, although it has declined slightly during the past three weeks. Production so far this year is larger than for any similar period for six years.

Price changes show either up or down in all districts except Mt. Olive and Pittsburgh. The greatest advance was made by Cambria, Somerset and Clearfield coals, with Pocahontas following closely. The biggest drop was in Kanawha coals. *Coal Age* Index of spot prices for bituminous coals was 226 on May 14, as compared with 220 for the previous week, with an average price of $2.73.

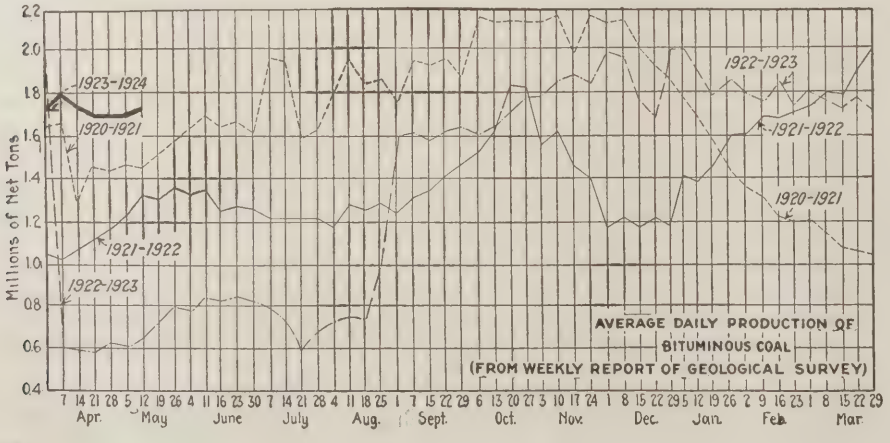


Mine Closings Continue in Middle West

More mines closed in the Midwest, causing spot prices in these districts to advance a trifle. In the East there is considerable optimism and operators feel confident that fuel stocks are low. Warnings issued by the Department of Commerce and by organizations, including the Chamber of Commerce of the United States, to consumers to buy coal now have resulted in more inquiries and while few orders have been placed producers and shippers are hopeful. There is a strong feeling that industrial plants are preparing to store.

Contracting has taken on new life and some contracts were reported closed. The U. S. Shipping Board opened bids last week for furnishing 1900 gross tons of either Pool 9 or 71 coal alongside New York harbor and received tenders ranging from $5.43 to $7. Contracts for small tonnages for industrial plants were closed on a basis of $3.25 per net ton f.o.b. mine for Pool No. 9, and at $3 per net ton f.o.b. mine for Pool 10 coal.

The export market continues flat. There were some inquiries but no definite business was reported. A couple of charters for French Atlantic destinations for old business were reported. Shipments from Baltimore during the first seven days of May amounted to 73,526 tons of cargo and bunker coal, and 26,780 tons of coke, a total of 100,306 tons of coal and coke.



A shipment that attracted considerable interest in Baltimore took place on May 11, when the steamship Winnebago loaded 5,229 tons of smithing coal for Portland and Seattle. This shipment is looked upon as the

start of further shipments to the Pacific coast by way of the Panama Canal. The vessel took bunker coal at Norfolk.

The Lake season has opened in nearly all directions. Shipments are heavy, close to a half million tons having arrived at the Head-of-the-Lakes during the first week of navigation.

"For the third successive week production of soft coal declined slightly," says the Geological Survey. "The total output in the week ended May 5 is estimated at 10,010,000 net tons, a decrease of 93,000 tons from the figure for the week preceding. May Day was partially observed as a holiday in some districts, and over the country as a whole it appears that it counted for about

Calendar year	2,400,000	6,824,000

(*a*) Subject to revision. (*b*) Revised from last report.

90 per cent of a full working day. Preliminary reports of cars loaded during the week of May 7-12 indicate slightly better conditions and it seems probable that production will total about 10,200,000 tons."

Dumpings at Hampton Roads during the week ended May 10 for all purposes totaled 359,002 net tons, as compared with 355,271 net tons in the previous week.

Production of anthracite continues on a basis of about 2,000,000 tons weekly. Domestic sizes are scarce, with demand heavy. Considerable coal is going into Canada. The steam sizes are slowing up, some producers sending heavy tonnages to storage, which enables the independent operators to dispose of their output to better advantage.

Midwest Slowly Slogs Along

The Midwest coal region is slogging along more and more slowly. A few more mines in both Indiana and Illinois have shut down, many of them for the summer. In central Illinois so few mines are operating that little but contract mine-run is shipped and as a result screenings are scarce. The spot price has risen a little as a consequence, but nobody needs to buy. Southern Illinois, gathering in about all the domestic business the state gets just now, is shipping enough lump and egg to bring out a steady flow of steam coals of ample volume to meet most requirements. losing only a little bit of rush steam business to the Springfield district.

Franklin County, though nearly half shut down and getting but 40 per cent running time for the other half, is preparing for an advance in domestic price June 1 from $4.10 to $4.35. The big operators insist they are going through with the plan of advancing the price 25c. a month throughout the summer, and that there will be few deviations. Just now there are a good many independents in the Carterville region offering lump, egg and nut at $2.75 @$3 and some of last month's orders have been extended by the bigger shippers at the April price of $3.85.

The Duquoin and Jackson County fields are shipping a little domestic up to $3.50 and screenings at $1.60. Mt. Olive district is almost at a standstill.

St. Louis "Quiet and Easy"

The St. Louis market is "quiet and easy." A little anthracite and smokeless is placed right along and there is not enough coke to meet a slow demand. However, there is

*Net tons, f.o.b. mines †Advances over previous week shown in **heavy type**, declines in *italics*.

Coal Age Index 226, Week of May 14, 1923. Average spot price for same period $2.73. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

little else doing on that market except a thin, but steady Standard district steam trade. Buyers will not believe that coal is going to go up during the summer. They appear to be waiting for another drop. One reason for this attitude is that the retailers failed to make good on their hint that they would raise prices May 1 when the field circular on many domestics went up 25c.

Kentucky Mildly Active

Eastern Kentucky is doing a little business every week but the desired rush of Lake trade has not been strong enough to create any furor. Industrial consumption and railroad business is light. Business generally is quite fair. The western end of the state, having recently settled its strike, is harder put for trade than the Harlan and Hazard fields because little of that coal goes to the Lakes, and it is difficult for it to penetrate the Chicago and Midwestern market because of Illinois and Indiana competition. Steam coal is generally draggy and not much activity is expected by most operators before the middle of June or the first of July. Prices have shown no marked change.

Northwest Wide Awake Now

Navigation opened with a rush at the Head-of-the-Lakes. It is the second latest opening of record, according to Duluth historians.

The new list of prices has been announced. They range as a whole about $2 below last year's opening: Kentucky lump, $8; splint lump, $7.50; Youghiogheny lump, $7; Hocking lump, $6.75; Youghiogheny & Hocking run of pile, $6; Youghiogheny screenings, $4.50; Hocking screenings, $4.25; Pocahontas lump, $12.50; mine run, $9; screenings, $6.75. Other prices have not been announced. Anthracite is selling at last year's figures. It is expected that prices will be announced at the end of this week.

The Milwaukee market is very quiet though the sharp reduction in price of Eastern bituminous coal on May 1 had the effect of stimulating buying in industrial circles to some extent. In addition to the arrival of forty-three cargoes of coal, car ferries brought in 18,427 tons of anthracite and 80,176 tons of soft coal during the month of April. The railroads contributed no anthracite, but delivered 109,612 tons of soft coal.

Western Business Quiet

Colorado bituminous producers had a fair week with no recessions in prices but the pick-up in their business was slight. There is a real demand both for bituminous and lignite slack at fair prices, not because the demand is stronger than usual at this time of year but because there is less coal screened now than is normal.

Business for Utah mines remains quiet. Weather is warm and working time has dropped so low that many experienced miners are leaving the field. Prices continue to fluctuate.

In the region around Kansas City, field prices have not changed and the situation is in no way improved over that of the last few weeks. Nobody is buying for storage. Householders are not taking advantage of slight reductions in retail prices and industrial consumers and railroads assert that Kansas coal will not store, hence they would be foolish to try it. The industrial contract market remains fairly steady, however.

Ohio Markets Show Little Change

Trade is quiet in the Columbus market. Buying for steam purposes is at a minimum and the general prosperity in industrial circles is not reflected in the coal trade. Large users are using their reserve stocks and show little inclination to come into the market. In the Cincinnati market the lower grades were kept moving by low prices, with better grades holding their own. A little spurt that resulted in better car supply in the Pocahontas fields is said to have been responsible for a better market for those coals. Operators and jobbers in the Cleveland market say that the general steam demand is no better than it has been for some weeks.

Demand for gas coal in the Pittsburgh district continues of fair proportions but there is no snap to the market. The utilities are running as well as usual at this time of the year, while the steel industry, which consumes considerable gas coals is running at a new high record rate.

In central Pennsylvania the new mine ratings under recently established distribution rules became effective on the Pennsylvania R.R. on May 10 and are being watched by operators. Under the new ratings some companies will get more cars and others less. Production during April in central Pennsylvania was 69,567 cars as compared with 79,542 cars in March.

Consumers in the Buffalo market see no reason for buying coal when supply is greater than the demand.

New England Markets Apathetic

The leading feature in the New England market is the distinctly firmer trend of Hampton Roads prices. With a relatively small output there has been enough increase in buying to warrant higher quotations f.o.b. vessel, but not only is there no improvement in demand at various rehandling plants but there seem few indications of prices any higher than those that have prevailed for nearly sixty days. Purchases continue on a hand-to-mouth basis and not yet have buyers generally shown any disposition to place orders more than a month or two in advance. Reserves are of only moderate size, but water power is ample in large areas and there continues the same apathetic attitude toward coal

that has been characteristic since quotations began to recede earlier in the year.

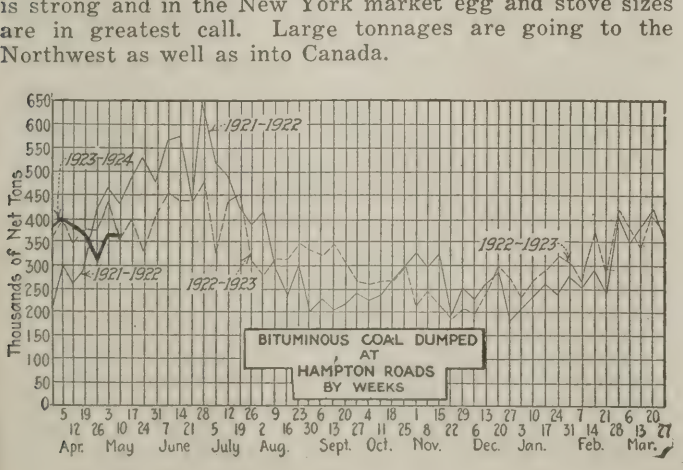
Higher prices at the Virginia terminals resulted in slightly better inquiry for Pennsylvania coal, although thus far what small business has come into the market has been confined almost exclusively to the choice grades. Even these have sold at what operators regard as bottom figures, costs considered, but frequent embargoes which shut off deliveries on contract also have had their bearing. At one time recently all five of the Hudson River gateways were practically closed to bituminous coal and shippers were obliged to send output temporarily in directions where coal does not usually flow in such volume. Part of the depression in Pennsylvania quotations the past week has been due to this factor.

While tonnage for transshipment at New York and Philadelphia is by no means heavy the aggregate for May probably will show an increase over totals for April. Transportation conditions by rail, of course, have contributed to tidewater movement. A considerable share of the coal actually dumped is for gas-making purposes and for railroad fuel, and there also is a certain amount that continues to go forward to points not easily accessible from Hampton Roads. Coastwise freights are easy at $1, Hampton Roads to Boston, on large vessels and barges, with steamers at 90@95c.

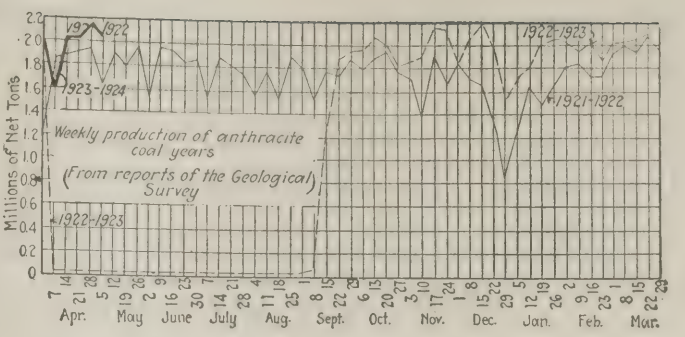
Slow Demand in New York Market

In New York demand was slow. Some operators assert that they are sold up for certain grades well into June while others complain of lack of business. Inquiries are on the increase, however, and operators and shoppers are optimistic. There were 3,400 cars at the local terminals on May 12. Philadelphia consumers are unwilling to buy anything out of the ordinary. Feelers have been put out by some consumers on big blocks of coal to run from one to two months. The feature of the Baltimore market centers in the export situation. Local demand is slow.

Lack of market for steam coal is serving gradually to reduce production in the Alabama field. Many mines dependent almost entirely upon spot demand are either closed or have curtailed production considerably.



Lake Navigation Gains Strength



Lake navigation, while not active from all ports, is gaining strength. More than 500,000 tons of coal have arrived at Duluth since May 5, when the first shipment was received, among it some anthracite, and other cargoes of hard coal are reported on the way. Arrivals at Milwaukee during the first ten days of May consisted of 80,629 tons of anthracite and 281,761 tons of soft coal. In the Columbus market the Lake trade is expected to be under full headway the latter part of May. Loading of bottoms is going on briskly.

During the week ended May 14 Lake dumpings amounted to 582,486 net tons of cargo coal and 23,525 net tons of fuel coal, making the season's dumpings to date 2,376,169 net tons of cargo coal and 94,277 net tons of fuel coal.

Strong Demand for Domestic Anthracite

Anthracite domestic sizes are readily absorbed. Demand is strong and in the New York market egg and stove sizes are in greatest call. Large tonnages are going to the Northwest as well as into Canada.

"The production of anthracite was well maintained during the first week of May," says the Geological Survey, "even though there was a slight decline in output. The nine principal anthracite carriers reported loading 38,643 cars, from which it is estimated that the total output, including mine fuel, local sales, and the product of dredges and washeries, was 2,021,000 net tons.

"Preliminary reports of loadings during the week May 7-12 indicate a higher rate of production during the week."

Production of Coke Declines Slightly

Production of coke in April was 3,206,000 net tons, as compared with 3,256,000 net tons in March, says the Geological Survey. To manufacture this tonnage of coke it is estimated that 7,408,000 tons of coal was consumed, of which 4,607,000 tons were used in byproduct ovens and 2,801,000 tons in beehive ovens. During the week ended May 5 the total output is estimated at 406,000 net tons, a decrease of 18,000 tons as compared with the week previous.

F. R. Wadleigh, Federal Fuel Distributor, has requested the National Retail Coal Merchants' Association and the American Wholesale Coal Association each to name a representative from its organization for membership on his Advisory Committee to study community coal storage, coal sales agencies and distribution.

How the Coal Fields Are Working

Percentages of full-time operation of bituminous coal mines, by fields, as reported by the U. S. Geological Survey in Table V of the Weekly Report.

Foreign Market And Export News

British Production Absorbed by Active Market; Output Sold Ahead

During the week ended April 28, Great Britain's mines produced 5,721,000 tons of coal, says a cable to *Coal Age*. This is a decrease of 104,000 tons from the output of the previous week, but within 21,000 tons of the weekly record output for 1922.

The Welsh coal trade, compared with its condition of a few weeks back, has become irregular. The unsettled state of other British markets has not yet affected Newcastle. Production of all classes of coal is now sold up for weeks to come, and it is not believed there can be no appreciable falling off in the volume and value of trade until July 1.

For the period ending June there is an active inquiry. Sellers ask for full rates, and get them without any difficulty. Supplies are very scarce all around, particularly in coking coals.

Efforts to reach a settlement of the question of the three-shift operation at the Welsh coal ports have not been successful. Following the refusal of the coal tippers and trimmers to accept the provisional agreement made with the operators, attempts have been made to secure a guarantee that the present high earnings, ranging from £6 to £9 per week will continue in force, but the operators decline to give any such guarantee. The Industrial Court appointed to inquire into the position will not resume its sittings until a deadlock in the negotiations is reported.

Statistics of the Board of Trade on coal exports for the month of April compared with the same month of 1922, follow, in tons:

	1923	1922
Germany	1,715,000	257,000
France	1,543,000	955,000
Italy	754,000	541,000
Other countries	2,829,000	2,343,000
Total	6,841,000	4,096,000

Export Demand at Hampton Roads Strong

Business at Hampton Roads had a livelier tone last week, with export trade booming and threatening to break all records for the past twelve months. A pick-up in trade with France and South America was one of the outstanding features of the market.

Stocks at the piers were cut down, and prices stiffened. The Norfolk & Western R.R. routed a large tonnage by rail to the West, and the result was reflected in diminished stocks at the piers. Coastwise trade was on the decline, but the bunker business held firm.

A generally optimistic tone was heard throughout the trade, with prospects for increasing business bright. Export trade is expected to continue to grow. Domestic business was falling off to the usual season's minimum. The car situation was improved, being about 75 per cent of normal, from the best opinion in the trade.

News Items From Field and Trade

ALASKA

The Alaska Legislature has taken action which will permit the territorial government **to co-operate with the U. S. Bureau of Mines in the maintenance of a mine-inspection system.** Under this arrangement B. D. Stewart will be mine inspector for the territory and supervising mining engineer for the Bureau of Mines, as well as the representative of the Secretary of the Interior in matters pertaining to leasing. The proposal to establish an Alaska Mining Development Board was defeated by one vote. The purpose of this board was to devise means whereby the mineral development of the territory could be stimulated. The bill carried an appropriation of $40,000.

ILLINOIS

The Pennsylvania Crusher Co., of Philadelphia, has opened an office in the Monadnock Building, Chicago, with C. S. Darling in charge.

The Illinois Mining Institute will hold its summer meeting on one of the Eagle boats, leaving St. Louis on the morning of Thursday, June 7, and cruising up the Illinois River to Starved Rock, near La Salle, Ill. The boat will return to St. Louis, arriving there about noon on Saturday, June 9.

Arrangements are being made to hold **an Illinois first-aid contest at Collinsville** on Saturday, June 23. The local arrangements are being taken care of by a committee of residents of that city, composed of two operators, two miners and three members of the Civic Association.

Sinking of the new Nason mine in Jefferson county has begun at last. Late in April work started on both the main shaft and the air shaft.

Donk Bros. Coal & Coke Co. is erecting one of the largest tipples in the state at Mine No. 4, near Edwardsville, Ill. The airshaft has been hoisting coal for two years and now the main shaft is about ready. The tipple will be wide enough for six tracks and will have a capacity of 6,000 to 8,000 tons of coal daily. It will be 85 ft. in height. The company also will install one 750-kw. and one 1,000-kw. turbine generators. Electric current will be supplied to the mine at Maryville as well as No. 4 mine.

The Chicago Collieries Co. will sink a mine three miles north of Catlin, near Danville. The shaft will be near the present workings, where a vast amount of coal is being stripped. The company controls 2,800 acres of land lying between the Kistler hill, west of Batestown, and the village of Catlin. At present the big shovels are stripping coal south of the hill and it is planned to sink the shaft at a point further south, which will give employment to more than 300 men. Railroad connections will be made with the Wabash at Catlin and with the Big Four and Illinois Traction System west of Danville.

INDIANA

The Akin-Burton Coal Co. is the name of a newly organized company in Terre Haute. The company will do a general mining business and has a capital stock of $50,000. The organizers are Charles T. Akin, Sedgwick R. Akin and Charles R. Burton.

The Glendale Coal Co., of Terre Haute, has filed a preliminary certificate of dissolution, as did the **Home Coal Co.** of the same city.

For the purpose of dealing in coal lands and leases, the **Bertelsen Coal Co.** has been organized in Evansville with a capital stock of $10,000. The organizers of the company are Jeppe Bertelsen, Katherine Bertelsen and Lowry Bertelsen.

The **Williams Coal Co.** has been organized in Evansville, with a capital stock of $200,000 to own and dispose of mine workings and mining grounds. The organizers are Robert R. Williams, Joseph Wastjer and William W. Gray.

Jos. W. Hays is just completing the organization of a corps of consulting combustion engineers to be known as **Jos. W. Hays and Associates.** The headquarters of the organization will be Michigan City.

Le Noir Coal Co. has changed its domicile from Terre Haute to Indianapolis, and created $150,000 of preferred stock.

The McDonald Block Coal & Clay Co. has been incorporated at Terre Haute; capital, $50,000; directors, Henry F. McDonald, Jesse W. McDonald, J. C. Coleman, Theodore S. Biggs, Harley McDonald, Fred Hermeling and Harold H. McDonald.

A committee representing the Indianapolis Federation of Community Civic Clubs will confer with officials of the Citizens Gas Co., of that city, in an endeavor **to induce the company to sell its coke direct to consumers.** The coke is now sold, it is claimed, to a Cincinnati jobber, acting as sales agent, who sells it to Indianapolis retail dealers. The gas company produces enough coke to supply every household in Indianapolis.

At the initial session for May of the Vigo County, Ind., Board of Mine Examiners, **permits to work with qualified miners were granted to 27 persons and certificates of qualification were issued to 23.** The board of examiners is composed of George H. Richards, Squire J. Carithers and George Stilwell. Due to scarcity of mine work at the present time the number of applicants is said to be smaller than the average.

IOWA

The Anderson mine, near Knoxville, Iowa, has been abandoned after 15 years' operation. Recently the mine began to fail and last week the machinery was pulled out. At one time over 100 miners were employed and a miners' train was operated between Knoxville and the mine.

J. A. J. Powers, of Knoxville, **has purchased 502 acres of coal land in Monroe County,** near Lovilia, where a stope mine has been in operation on the land for several years. Connections will be made with the Chicago & Northwestern R.R.

The Elmyra Coal Co., of Kansas City, has been incorporated under the Missouri law, with a capital of $40,000.

Tests made in Cedar township and Orange township, near Albia, **show a vein of coal at a depth ranging from 150 to 600 ft.** below the surface. Ten test holes have been sunk and it is expected to complete the tests by July 1. If the coal deposits prove as good as are now indicated a local mining company will be incorporated to operate the mine.

KENTUCKY

The following coal companies were recently incorporated: **Burclut Coal Co.,** Bell; capital, $30,000; incorporators, J. W. Burnett, W. L. Burnett, G. A. Clutts and A. E. Clutts, all of Middlesboro. **Doward Manning Coal Co.,** Jefferson; capital, $24,000; C. P. Downard and Elmore Manning, Louisville, and A. A. Deuser, New Albany, Ind.

The Elkhorn Coal Corporation has resumed dividend payments on its preferred stock by the declaration of a payment of 75c. a share payable on June 11 next to stockholders of June 1. From 1916 until December last year the company had paid dividends regularly at the annual rate of $3 a share on the preferred stock, but in February this year the action on the dividend was deferred. At the time the reason for the action was said to be conditions in the coal industry.

MASSACHUSETTS

James J. Phelan, State Fuel Commissioner, in his final report filed on May 5, **recommends that Massachusetts continue the use of substitutes** for anthracite, and consumers wherever possible should have their winter coal delivered during the summer.

Clinton S. Marshall, general manager of the Worcester division of the American Steel & Wire Co., has announced that because of the high cost of coal that plant will substitute electricity for power. The concern will continue to use coal for its heating plants, but will purchase power.

MINNESOTA

J. H. Bell, one of the largest stockholders of the Carnegie Fuel Co., and **J. N. Stonerood,** both of Pittsburgh and on the company's directorate, inspected the docks of the company at Duluth, May 1. Mr. Bell said that the docks had never been so bare of coal in their history and that he took a pessimistic view of the anthracite outlook. His company, he said, would accept no large contracts for anthracite and would supply the retail trade to a large extent.

MISSOURI

Thomas Wood of Centerville, Ia., has **leased 2,000 acres of land west of the Kirksville** city reservoir and extending to large leaseholds held by another Iowa firm in the same district. Wood will develop the field and will sink a mine.

The Big Creek Coal Co., of Kirksville, Mo., has announced that it **will install machines in its mines** there and has reached an agreement with the miners on a machine scale, as a result of which there should be a marked decrease in the price of coal in Kirksville next winter. According to officials of the company coal mined in this manner will cost about $5 or $5.25 a ton next fall, while this same coal was selling for $7 a ton last winter.

NEW YORK

E. J. Leonard, of Syracuse, has been awarded the contract for furnishing and delivering 3,000 tons of bituminous coal to the Onondaga Sanitorium. The awarding of contract for delivering 2,000 tons of similar coal to the County Home at Syracuse was deferred.

In keeping with the program mapped out by the Association of Railway Executives in their meeting in New York last month **the Erie RR. has been storing coal steadily,** Frederick S. Underwood, president, said recently. "We now have a supply of thirty-six days' coal on hand, and by Sept. 1 will have stored up a supply for ninety days. The Erie's shops have now brought the road's locomotive equipment up to normal, bad-order locomotives averaging about 15 per cent of the total on line, and by Oct. 1 it is expected that freight cars awaiting repairs will be reduced to 5 per cent of the total on line."

OHIO

The following coal companies were recently chartered: **The Webster Coal & Iron Co.,** Dayton; capital, $10,000; incorporators: Oscar Blum, Joseph Eselafsky, Esther Eselafsky, Bessie Blum and Maurice M. Linder. **The Blowers Coal Co.,** Bellaire, $200,000; George A. Blowers, M. M. Weinstein, C. H. Poole, A. E. Clark and D. B. Brooks. **The Nelsonville Consolidated Coal Co.,** Nelsonville; $25,000; D. H. Armstrong, R. S. Oxley, D. F. Shafer, A. H. Schory and O. P. Amann. **The Commercial Coal & Coke Co.,** Cleveland; capital, $10,000; Frederick L. Leckie, Tracy H. Duncan, Theo. C. Robinson, Lee C. Hinslea and Joseph A. Schlitz. **The Euga Coal Mining Co.,** New Lexington; capital, $5,000; J. A. Curtis, R. F. Roberts, M. Herstam and E. Holwick.

The Bingham Coal Co., Cadiz, has been incorporated with a capital of $250,000 to mine and sell coal in the eastern Ohio field. Incorporators are: Charles W. Wenner, F. J. Reese, A. H. Finnical, R. L. Timmons and Albert Wagoner.

The L. & L. Coal Co., of Bellaire, has been chartered with capital of $10,000 by W. J. McGraw, Joe Hodge, Paul V. Waddell, and James O. Wagoner, to mine and deal in coal and coke at wholesale and retail.

H. K. Keyser has succeeded O. M. Richardson as manager for the Old Dominion Coal Co.

Engineers have begun preliminary work for **construction of a fifty-one coke oven unit and byproducts plant** for the Trumbull Cliffs Furnace Co. at Warren. Construction will cost $3,000,000.

J. W. Johns, chairman of the nomination committee of the American Wholesale Coal Association, has asked that the preferences of the members be forwarded to him in

care of the Atlas Fuel Corporation, of Pittsburgh, as soon as possible, so that it may be known who has been settled upon for election as officers when the organization meets in Cincinnati, June 11 and 12. **Charles L. Dearing has been asked by President Morton to act as toastmaster at the annual banquet.**

The Columbus Board of Education has settled its coal problem for the coming year by purchasing 12,000 tons of mine-run Hocking coal from the Colonial Coal Co., of Columbus, at $4.29 delivered. This is a saving of approximately $20,000 over last year when 1½-in. lump was purchased at $6.19. Bids on mine-run which were opened May 7 ranged from $4.29 to $5.79 per ton delivered to the various school buildings.

PENNSYLVANIA

Senator Joseph O. Clark, Indiana, May 7, **introduced a series of four bills relating to the mining laws** of the State. One of these amends an act of 1921 relating to anthracite mine inspectors and relieves the inspectors from furnishing bond to the commonwealth. Another amends an act of 1911 relating to bituminous inspectors, relieving them of furnishing the bond. Two other Clark bills amend the same laws, one making a change in respect to Anthracite Mine Inspectors' Examining Board which under the act of 1921 could not sit more than forty days. This limit is removed by an amendment and the Chief of Mines is given the right to determine from time to time the maximum number of days for which the members of the board shall receive compensation. A minor change is the elimination of the requirement that the board's clerk shall also be a stenographer. The Bituminous Mine Inspectors' Examining Board under the act of 1911 was not restricted as to the number of days it could sit, but the Clark amendment provides that the Chief of Mines shall have the same right given him under the anthracite board bill amendment to fix the maximum number of days.

A bill offered by Asa K. DeWitt, Luzerne, **provides for approved electric motors and requires attendants at ventilating fans in anthracite mines.** The measure prohibits one year after the passage of the bill the use in any anthracite mine of electric motors in which locked safety lamps are used, unless they bear the approval plate of the U. S. Bureau of Mines and have also been approved by the Chief of Mines of Pennsylvania. An attendant must be constantly at fans used to supply air to underground workings and he shall regulate the speed of the fan according to the instructions of the mine foreman. Violators of the measure are subject to a fine of $100 to $200 or two months' imprisonment, or both.

Following an experiment in the **use of carbonic-acid gas in an attempt to extinguish mine fires,** a group of scientists headed by Dr. W. A. Hamor, assistant director of the Mellon Institute of Research at Pittsburgh on May 10 entered the Bitner coal mine of the H. C. Frick Co., near Connellsville, which has burned continuously since November, 1922. **A partial exploration of the burned underground area failed to disclose any fire** in the coal seams that have housed a roaring furnace for six months.

Agreements have been filed in the Dauphin County Court **withdrawing three appeals involving the state anthracite tax.** They were in the cases of the Kingston Coal Co., the Lehigh & Wilkes-Barre Coal Co. and the Spencer Coal Co. The appeals were dropped pursuant to an agreement that they would be withdrawn if the Supreme Court sustained the decision of the lower court in the test case of the Thomas Colliery Co. State coal taxes involved and now payable to the State aggregate $11,807.57.

The Amend Coal Co., of Greensburg, has contracted with the Roberts & Schaefer Co. for the installation of a Marcus screen in its tipple at Newcomer.

A delegation of twenty-five Senators and several bituminous operators on May 8 called upon Governor Pinchot to **urge him to favor an amendment to the administrative code by which the Department of Mines would be retained.** The code makes the department a bureau in the Department of Labor and Industry and the Senators told the Governor they believed that the mining industry and mine workers would be better protected if the present plan is continued. Governor Pinchot said he had not changed his mind relative to the advisability of creating a bureau for the regulation of mining, but that he would take the matter under advisement.

State charters have been issued at Harrisburg for the following bituminous companies: **Little Alps Coal Co.,** Newell; capital stock, $25,000; treasurer, A. M. Speers, Belle Vernon. Incorporators: C. O. Downer, Newell; S. M. Speers, Belle Vernon, and Arthur Hawthorne, Monessen. Purpose: Mining and preparing coal for the market. **Argentine Coal Mining Co.,** Pittsburgh; capital, $300,000; treasurer, E. A. Morris, 2023 Wendover street, Pittsburgh. Incorporators: E. A. Morris and R. M. Carpenter, Pittsburgh, and Will R. Crowthers, Mt. Lebanon. Purpose: Mining coal and buying, selling and dealing in coal lands.

Union workers in the Jermyn colliery of the D. & H. Co. at Jermyn **are preparing to make a membership drive** among the employees at that mine before declaring a button strike. This action was decided upon at a meeting which was addressed by District President William J. Brennan, who advised the men to first conduct a drive to affiliate all employees with the organization before calling a strike.

Fire of unknown origin on April 20 totally **destroyed the washery of the Susquehanna Collieries Co.** at Nanticoke, causing a property loss of approximately $150,000 and causing idleness of sixty employees. The structure, which was one of the largest washeries in the anthracite region, was situated near the site of No. 7 colliery of the Susquehanna company, which was destroyed by fire on Feb. 6.

The Berwind-White Coal Mining Co. presented a petition to the Somerset County Court on May 10 asking for a rule to show cause why an attachment should not be issued for Powers Hapgood, Joseph Foster and John Brozzini, organizers of the United Mine Workers, for contempt of court for alleged violation of the strike injunction granted a year ago. A rule was issued by Judge John A. Berkey and made returnable at Somerset May 21. It is alleged by the coal company that the defendants stopped working miners of the Berwind-White company on their way to work in Windber during the last few days. The petition sets forth that the defendants told the miners that the company's mines were a prison and workmen were not Americans unless they joined the strikers.

After a four-day hearing on a petition to make permanent the receivership of the Von Storch Collieries Co., of Scranton, **Federal Judge C. B. Witmer dismissed George R. McLean,** of Wilkes-Barre, **as temporary receiver** and directed that Edmund B. Jermyn, Scranton coal operator, be elected a member of the company's board of directors. Judge Witmer said that **Mr. Jermyn would represent the court as referee** and that no other order would be made at this time. He added that he hoped the "warring interests" of the company would agree, and if they could not he would direct that an answer be filed to the plaintiff's bill of particulars and appoint a permanent receiver to wind up the concern's affairs, if necessary. Mr. McLean was appointed receiver last week at the request of Henry E. Meeker, of New York, owner of 40 per cent of the company's stock. Mr. Meeker also filed the petition for a permanent receiver.

W. P. Boland, an independent coal operator of Scranton, **has offered the officials of Wilkes-Barre a flat rate of $1 for every ton of coal mined from under the river common.** Two other offers of something like 47c. and 52c. per ton were received, but the identities of those making the tenders were not divulged. It is estimated there are at least 1,000,000 tons of coal under the common.

Members of the United Mine Workers in the anthracite fields have been asked to contribute to a fund of between $75,000 and $80,000, which is being raised to pay for the John Mitchell memorial monument to be erected in Scranton.

After being idle for five weeks, **350 miners employed at the Mount Lookout colliery** of the Temple Coal Co. at Wyoming **are back at work.** Their strike was ended by the company's promise to furnish places for forty men previously laid off because of a squeeze in an underground tunnel. The strike was one of the longest affecting a single colliery in recent years.

W. P. Jennings, general superintendent of the Pennsylvania Coal Co., **entertained the executive force** of the Underwood colliery, located at Throop, at a dinner recently at the Scranton club to celebrate the record made by the colliery in preparing and shipping 10,000 tons of coal in one working day of eight hours. It is believed that this is the record for any colliery in the anthracite region.

H. C. McIlveen, formerly with the Phelps-Dodge Corporation, Clifton, Ariz., is now connected with the engineering department of the Hillman Coal & Coke Corporation, of Pittsburgh.

Twelve additional ovens have been rebuilt by the Corrado Coke Co. at the old Nellie plant near Vanderbilt, making a total of 56 now in blast. Eighty-seven ovens are burning at the Clarissa plant of the same company.

The bituminous coal tax bill of Representative Kohler was **recommitted to the House** Ways and Means committee for a hearing on May 1. The bill provides for a 1½ per cent tax on soft coal, providing for a tax similar to the anthracite tax law.

The plant of the American Briquet Co. near Lykens was destroyed by fire on May 7. The loss is estimated at about $400,000. The plant produced an average of 8,000 tons monthly and gave employment to 55 men.

Notice of a change of corporate name has been filed by the **Berge-Fraser Co.,** Lackawanna County, which will be known as the **Berge Coal Co.**

A charter was issued recently to the **Irwin Valley Coal Co.,** Philadelphia, with a capital stock of $10,000. Warren W. Rush, of Melrose Park, is treasurer. The purpose of the company is mining and preparing coal for the market. The incorporators are William H. Shuster, Wayne; Warren W. Rush, Melrose Park, and George H. Detweiler, Tutledge. Another company incorporated was the **Provins-Ainsley Coal Co.,** Masontown, $10,000 capital H. Gilmore Provins, Masontown, treasurer. Purpose, mining coal and manufacturing coke. Incorporators: George P. Cox, Brownsville; H. Gilmore Provins, Masontown, and James Ainsley, Masontown.

The Fairmont Mining Machinery Co., Fairmont, W. Va., has been awarded the contract **to install new shaker screen tipple equipment for the Bertha-Consumers Co.,** at its Gould Mine, Wilson, on the Peters Creek branch of the Monongahela division of the Pennsylvania R.R.

The Crawford Machinery Co., of Pittsburgh, has removed from the House Building to 1117 Bessemer Building.

Henderson Steele, of Uniontown, has been **appointed ancillary receiver of the Southern Connellsville Coke Co.** by Judge R. M. Gibson in the U. S. District Court at Pittsburgh. The company has a branch office at Cheat Haven, Fayette County. The appointment was made on the petition of George W. Thompson, of Connellsville, a stockholder of the company, in which it was averred that on March 1, 1923 Judge Baker in the U. S. District Court of the northern district of West Virginia, appointed J. H. McDermott, of Morgantown, W. Va., receiver for the company.

A corps of engineers attached to the **Western Maryland Ry.** are located at Meyersdale and ,it is reported, **will survey a branch line** from that place to **Jennings, Md.,** with a view of tapping rich coal deposits in southern Somerset County and northern Garret County, Maryland.

A state charter has been issued for the **Cherry Valley Anthracite Mining Corporation,** of Mildred. Its capital stock is $5,000 and Joseph P. Murray, 921 South Fiftieth Street, Philadelphia, is the treasurer. The treasurer, Frank S. Muzzly, 7320 Bryan Street, Mt. Airy, and F. Stanley Saurman, Churchville, are the incorporators.

The Sober Coal Mining Co. has been incorporated in Delaware with a capital of $50,000 by James Sober, Washington, Pa.; J. L. Brenner, J. M. Brenner, Pittsburgh.

The Glen Alden Coal Co. has purchased the Exeter Machine Co. works and property at West Pittston. The deal is said to have involved an outlay of $500,000. W. W. Inglis, president of the Glen Alden Coal Co., stated that the company does not contemplate immediately to operate the plant, but made the purchase for emergency purposes to provide a suitable machine shop for the manufacture and repair of breaker and mine machinery for its use when deemed advisable to take over operation of the shop.

Herbert Lloyd, president of **The Electric Storage Battery Co.,** Philadelphia, **has announced a plan by which employees** who have been continuously in the service of the company for two years or more **may become stockholders in the company.** The plan permits employees to purchase one share of common stock of the company at $53 per share for each $500 of his or her annual compensation, but not exceeding 20 shares to any one employee.

The Link-Belt Co. has removed its **Pittsburgh branch office** from 1501 Park Building to new and more commodious offices at 335 Fifth Avenue. T. F. Webster, manager of the Pittsburgh office, says that larger space and the more convenient location was imperative because of the large volume of business transacted during the past year and which promises to continue during the coming fiscal year.

A state charter has been issued at Harrisburg for the **Amy Coal Co.**, Philadelphia, the purpose of which will be to mine and deal in coal and coal lands. The company has a capital stock of $500,000 and its incorporators are Harry E. Bird, treasurer, Fifteenth and Market Streets, Philadelphia; John Barnes, Haverford, and E. L. Clarks, Cheltenham.

The following bituminous coal companies have been incorporated: **Brooks Coal Co.**, Normalville, capital $20,000; J. C. Henry, Connellsville, treasurer. He, with C. H. Brooks and Carl C. Brooks, Normalville, are the incorporators. **Nicewonger Coal Co.**, Greensburg, $25,000; Vance E. Booher, 140 North Main Street, Greensburg, treasurer. The incorporators are Lewis Nicewonger, Luxor; Hallis E. Nicewonger, Greensburg, and John H. McElveen, Greensburg. Both companies will mine coal and manufacture coke and byproducts.

SOUTH CAROLINA

Sealed proposals will be opened by the Superintendent of Lighthouses, Charleston, at noon, May 25, 1923, for approximately **4,000 tons of steam coal** (bituminous) and **175 tons stove coal** (anthracite), as required during the fiscal year 1924, delivered at Charleston. Information upon application.

WEST VIRGINIA

Output of the Island Creek Coal Co. in April amounted to 204,000 tons and brought the four months' total up to 830,000 tons, compared with 1,348,000 tons in the first four months of 1922. The four months' earnings were approximately $7.50 a share, or within 50c. of the yearly $8 dividend requirement.

A fire completely wiped out the town of Burke, McDowell county, 25 miles west of Bluefield, April 20, rendering more than a thousand persons homeless and destroying property valued at a million dollars. The fire was checked after it had spread to the adjoining village of Keystone and had destroyed three buildings there. More than 100 buildings in Burke were burned, including 25 cottages belonging to the Houston Coal & Coke Co.

J. W. Swanner and Edward Reynolds, West Virginia miners, **were shot and killed** at the mining camp of Vulcan, near Pomeroy, May 9, by J. E. Miller, a coal miner. Miller gave as his reason that he feared the two men had come to kidnap him and take him back to West Virginia in connection with the Logan armed march. That the killing of Swanner and Reynolds, witnesses for the state in the cases against C. F. Keeney and others for complicity in the murder of Logan County deputy sheriffs, was a part of a plot is charged by A. M. Belcher, of counsel for the state, and the charge is also made by L. Crary Davis, prosecuting attorney of Meigs County, that the killing of the two witnesses was cold-blooded murder. Swanner had in his pocket a letter from A. M. Belcher offering Miller immunity if the latter would return to West Virginia to testify in the armed march trials.

The Sanfield Coal Co., of Fairmont, has been organized with a capital stock of $1,700,000 for the purpose of operating in northern West Virginia. The size of the capital stock presages operations on a large scale. Heavily interested in the new company are M. W. Ogden, C. F. Crane, M. C. Lough and A. C. Lyons, of Fairmont; Harry E. Davisson and James G. Kidwell, of Clarksburg.

The King Fuel Co. expected to begin the production and shipment of coal about May 1, after two years preparation in constructing a modern plant not far from Christian, near the dividing line between Mingo and Wyoming counties.

Charters were granted recently to the following coal companies: **Appalachian Fuel Co.**, Fairmont; capital, $50,000; incorporators, Harvey H. Staggers, Mabel F. Staggers, Dan R. Lawson, Edith A. Lawson and E. A. Russell, all of Fairmont. **White Rose Coal Co.**, Shinnston; capital, $75,000; incorporators, Irvin Smith, H. J. Wagner, George Beck, William Beck, Smithton, Pa., and John Parachino, Greensburg, Pa. **Preston Smokeless Coal Co.**, Fairmont; capital, $75,000; incorporators, J. S. Mallory, Gertrude W. Mallory, Shinnston, W. Va.; H. S. Keister, Toyie A. Keister and M. B. Simonds, Fairmont.

The G. E. Burgess Coal Co. will operate in the neighborhood of Sand Run on the Charleston Division of the Baltimore & Ohio R.R., having just been organized with a capital stock of $10,000. Organizers of the new concern include G. E. Burgess, D. F. Fenney, D. F. Bearus, of Sand Run; Ray Jones and L. W. Jones, of Elk Garden.

A number of the smaller mines along the line of the Baltimore & Ohio in northern West Virginia are closing down because of low prices and lack of orders.

Five West Virginia coal companies have surrendered their charters and discontinued business. They are the Wanego White Ash Coal Co., Big Clear Creek Coal & Land Co., Carmen-Litten Coal Co., the Ritter Coal Co. and the Aileen Coal Co.

The tipple and bin at Mine No. 7 of the **Carbon Fuel Co.** on Cabin Creek, in the Kanawha field, having been destroyed by fire about two years ago, **a new tipple and bin has been in process of construction** embodying many improvements. Work on the new structure is nearing completion and the company will be able in a short time to use the new equipment which was installed by the Kanawha Manufacturing Co., of Charleston, at a cost of about $60,000.

The power house of the Hutchinson Coal Co., near Mason City in Mason County, **was destroyed by fire** a few weeks ago. There is a difference of opinion as to what caused the fire, one report received being to the effect that it was as a result of an overheated smokestack, and one to the effect that it was of incendiary origin.

WASHINGTON, D. C.

The Interstate Commerce Commission announces **the resignation of Robert E. Quirk as chief examiner**, effective June 15. He is to be succeeded by Ulysses Butler, formerly assistant chief examiner, who will in turn be succeeded by Charles F. Gerry, who has been an attorney-examiner for the commission.

Frank McManamy, of Washington, D. C., has been appointed a member of the Interstate Commerce Commission to succeed W. W. Daniels, of New Jersey, resigned to become professor of transportation at Yale University. Mr. McManamy is the labor representative on the Commission. He is 53 years old and has been connected with the I. C. C. and the Railroad Administration for 15 years. Prior to entering the government service he was a railroad worker.

A paper on "The Origin and Destination Weighing of Coal in Carload Lots" will be delivered during the course of the sixteenth annual conference on weights and measures which will be held at the Bureau of Standards in Washington May 21 to May 24. Another paper is entitled **"Retail Sales of Coal and Coke."**

CANADA

The Denver Rock Drill Mfg. Co., of Denver, Col., has discontinued its branch at Toronto and has established **a new branch at Montreal.**

Jung Low, a Chinese miner, was responsible for the explosion in No. 4 mine of the Canadian Collieries at Cumberland, Feb. 8 last, that cost the lives of Jung and 32 other miners, according to the report of an investigation of the disaster made by George Wilkinson, official investigator for the government. According to Mr. Wilkinson evidence obtained indicated that while working in the mine Jung attempted to light a cigarette, when the charged atmosphere exploded and burst into flames.

Thomas G. Shiels, of the Elias Rogers Co., Toronto, told the Commons committee investigating the fuel situation that last summer he had brought in a carload of **Alberta anthracite and had found that it in no way compared with American anthracite.**

The Toronto Wholesale Coal Dealers Association is making arrangements to send a large delegation to the annual convention of the American Wholesale Coal Association in Cincinnati on June 12 and 13.

The British Empire Steel Corporation reports coal production for the first four months of the year of 1,851,954 gross tons, as compared with an output of 1,074,045 gross tons during the corresponding period

The Vancouver city council has denied the application of a local syndicate, asking **for right of entry into Stanley Park** for the purpose of developing a seam of coal that has been found on the shore of the park.

The Mount Cavel Collieries, Ltd., of Edmonton, Alta., has been incorporated to acquire and operate mines in Jasper Park, Alta., with an authorized capital of $200,000, by Samuel L. Crocker, Samuel R. Wallace, H. McCoy and others.

Alexander Howat, deposed Kansas District president of the United Mine Workers of America, who was detained at McAdam Junction, N. B., by the Canadian immigration authorities while on his way to address the coal miners in Cape Breton, which detention was later affirmed by the Department of Immigration at Ottawa, has left Houlton, Me., for New York, according to a newspaper dispatch. "The action of the Canadian authorities in denying me admission to the country is an outrage," Howat said before leaving. "If I am stopped any other working man can be refused admission when there is no just cause."

W. F. Carroll, chairman of the House of Commons Committee investigating the coal supply, states that **English capitalists are prepared to open up and operate undeveloped coal areas at Mabou**, on the western coast of Cape Breton, if the government will facilitate transportation by providing railway extensions. The area has the advantage of possessing a harbor much closer to Montreal than Sydney or Louisburg. A representative of the British interests concerned is now in Canada and prepared to go ahead with the project.

An agreement has been completed between operators of coal mines in the Grand Lake district of New Brunswick and the Canadian National Railways, under which **much larger quantities of coal from the Minto mines will be used by the railways** during the coming year than ever before. Details of contracts calling for the tripling of the tonnage for the year have been arranged. Construction of a new spur line five miles in length to connect Minto with the Canadian National Railways at Chipman also is planned.

Obituary

E. L. Stafford, superintendent of the Carlswell shafts of the Houston Collieries Co., Carlswell, W. Va., died suddenly on May 2.

Joseph Reese, who for more than 20 years had been superintendent of the Temple Coal Co. at Blakely, Pa., died on May 5. Mr. Reese was 68 years old. He was placed on the retired list a few years ago.

John Irwin, 84 years old, the first H. C. Frick Coke Co. pensioner, died at his home in Connellsville, Pa., on April 29. He had been in the employ of the H. C. Frick Coke Co. 27 years at the time he was placed on the retired list.

William H. Reynolds, well known to a large number of friends in the Pittsburgh district as a miner and writer of mining life and experiences, died at his home, Butler, Pa., April 24, 1923, following an operation for appendicitis, at the early age of 47 years. Mr. Reynolds is best known and will be long remembered by many who have read with deep interest his book entitled "In the Carbon Hills." It is a true picture of mining life, filled with pathos and humor. Mr. Reynolds is survived by two brothers, J. T. and S. C. Reynolds, both now acting as mine inspectors.

Alexander H. Ross, a member of the firm of A. H. Ross & Co., coal dealers, Newark, N. J., died May 1. He was seventy-four years old. His brother, Robert L. Ross, with whom he was in business, is a former Receiver of Taxes and also was a member of the City Tax Board of Newark. Alexander Ross was born in New York, Sept. 11, 1848. He started in the coal trade fifty-seven years ago as an employee of the Delaware & Hudson Canal Co. In 1889 he organized the Ross concern with his brother. Mr. Ross was not married. Besides his brother, he is survived by a sister, Miss Elizabeth J. Ross.

Trade Literature

"Oswego" Internally Fired Water-Tube Boilers. A. D. Granger Co., New York, N. Y. Bulletin No. 2. Pp. 19; 8 x 10 in.; illustrated. Describes both the type A and type B boilers, the latter having downdraft Hawley type grates. Key tube plates are also featured, the use of which eliminates the gasket joints on the head.

M-S-A Playground Equipment. Mine Safety Appliances Co., Chamber of Commerce Building, Pittsburgh, Pa. pp. 25; 8 x 10 in.; illustrated. This book contains a complete list of outfits for playgrounds. Among some of the apparatus shown are slides, ocean wave, merry-go-round, rocking boat, teeter ladders, swings, and horizontal bars. Information is given as to size and arrangement of playground, surfacing and grading, fencing, lighting, with plan of a typical school playground. The H-H inhalator is shown with description of method of procedure in its use. Price list accompanies the bulletin.

Graver Zeolite Water Softener. Graver Corp., East Chicago, Indiana. Bulletin 509. Pp. 8, 8 x 11 in., illustrated. Describes the effect of the softener on hard water.

Bristol's Recording Gauges for Pressure and Vacuum. The Bristol Co., Waterbury, Conn. Catalog No. 1006. Pp. 83, 8 x 10 in., illustrated. Contains charts showing ranges covered and describes utility of recording gauges, also liquid level gauges, simplicity of construction, with partial list of applications.

Traffic News

The embargo placed by the New York Central R.R. against all freight destined to points on or via the Boston & Maine R.R. was **entirely cancelled May 10.**

The embargo placed by the New York Central R.R. against all freight destined to points on or via the Boston & Albany R.R. was **entirely cancelled May 10.**

An issue of $17,000,000 railroad equipment trust certificates has been authorized by the directors of the New York Central, Michigan Central and the Big Four railroads. Orders for the equipment, costing about $23,000,000, that is to be obtained through the funds from these certificates and cash from the company treasury, have already been placed, it is understood.

In a complaint brought by the Milwaukee-Commerce Commission, **the Tioga Coal Co.,** operating coal mines in the Gauley region of West Virginia, **urges that the Baltimore & Ohio R.R. be instructed to extend to it an adequate daily car-rating allotment,** joint through rates, and rates which are not higher than the "outer crescent" basis of rates to Western points of destination, and rates not more than 15c. per ton over the Fairmont district rates to Eastern points of destination.

S. D. Warriner, president of the **Lehigh & New England R.R.**, in his report for the year ended Dec. 31, 1922, says that the **strike in the anthracite region caused a decrease in the railway operating revenues** from anthracite freight of $565,437.88, as compared with 1921, while revenues from bituminous-coal freight and from merchandise freight show increases of $68,-120.83 and $406,702.38, respectively. Miscellaneous freight carried by the road during 1922 was 6,327,114 net tons of which there was 2,579,470 net tons of anthracite, 1,603,634 net tons of bituminous coal and 23,871 net tons of coke. In 1921 5,943,780 net tons of miscellaneous freight was carried, of which 2,840,356 net tons was anthracite, 1,492,643 net tons bituminous coal and 26,996 net tons coke.

Rates charged on coal in carloads from and to points in Missouri during the federal control of railroads were not unreasonable, in the opinion of I. L. Koch, an Interstate Commerce Commission examiner. In a tentative report on the complaint made by the McGrew Coal Co., of Lexington, Mo., he recommends that the complaint be dismissed. That rates lower than those charged the McGrew company were contemporaneously in effect for greater distances is not held to be a sufficient reason to condemn a rate. The coal company also declared that the rates were violative of the Constitution of the State of Missouri. In that connection the examiner says: "The commission's powers to adjudicate complaints of this nature are derived solely from the transportation and interstate commerce acts. Those laws do not give it jurisdiction to administer either the common law or any state constitution or statute. The standard of reasonableness embodied in the Missouri Constitution is not controlling up this commission.

The valuation set on the Virginian Ry. and its terminals by the Interstate Commerce Commission **will be discussed at a public hearing** to be held in Washington May 23.

The New York Central R.R. issued an embargo May 9 on all freight destined to all points on or via the Central New York Southern R.R., on account of advices from the Central New York Southern R.R. as to inability to operate.

C. E. Tuttle, of the Tuttle Coal Corporation, of New York City, **has been elected a director of the Pittsburgh & West Virginia R.R.** Henry E. Farrell, of Pittsburgh; William R. Nicholson and Asa S. Wing, of Philadelphia, and Ernest Stauffen, Jr., of New York, were re-elected directors. The following executive committee was chosen: William H. Coverdale, John B. Dennis, Henry E. Farrell, Haley Fiske, George P. Smith and Richard Sutro.

The Sewell Valley Ry. is not entitled to a larger proportion of joint rates on coal than it is now receiving from the Chesapeake & Ohio, in the opinion of William B. Hunter, an attorney examiner for the Interstate Commerce Commission. In his report to the commission, Mr. Hunter recommends that the Sewell Valley company's complaint be dismissed. The Sewell Valley company contends that the coal traffic delivered it from the Greenbriar & Eastern must be hauled up a steep ascent of 21 miles, which results in operating expenses which make its share of the joint rate non-compensatory. Mr. Hunter suggests that the Sewell Valley is not suffering from the alleged unremunerative coal traffic from the Greenbriar, but probably from its control in the financial interest of the Meadow River Lumber Co. and the Lookout R.R. and from the fact that it has not been equipped to handle its freight traffic economically.

One of the largest railway electrification projects yet undertaken is involved in the contract just closed by the Westinghouse Electric & Manufacturing Co. with the Virginian Ry. It calls for the electrification of 213 miles of track between Roanoke, Va., and Mullens, W. Va., and includes an order for electric locomotives, power house, transformer stations and other necessary apparatus. The division to be electrified crosses the Alleghany Mountains. The contract involves the expenditure of $15,000,000.

In a complaint bronght by the Milwaukee-Western Fuel Co. the Interstate Commerce Commission decided April 26 that rates were unreasonable on coal, in carloads from the Princess, Kilgore and Norton branch on the Ashland Coal & Iron Ry. to Toledo for transshipment by lake during federal control. A rate of $2.15 a ton was charged. The commission held $1.55 to be a fair rate and ordered reparation with interest paid on rates more than $1.55 a ton.

The Coal, Coke & Iron Ore Committee, Central Freight Association Territory, announces a public hearing at 10 a.m. (daylight-saving time), May 24, at the Chamber of Commerce Building, Pittsburgh, Pa., **to consider the rate on bituminous coal,** carloads, from mines on the Baltimore & Ohio R.R. in the Pittsburgh-Youghiogheny (Connellsville-Finleyville, Pa., etc.), to Cincinnati and Hamilton, Ohio. It is proposed to advance the rate to $2.33 per net ton, to correct a clerical error. At that time also a hearing will be held to consider the **rate on bituminous coal, carloads, to Westerville, Galena and Sunbury, Ohio, via the Pennsylvania R.R.** from mines on the Sandy Valley & Elkhorn, Long Fork and Millers Creek railroads. It is proposed to advance the rate to $2.14 per net ton to remove Fourth Section violation.

The net income of the Pennsylvania Railroad and its affiliated companies in 1922, according to the annual report, was $32,382,058, an increase of $8,074,389.15 when compared with 1921. There were carried over its lines 194,856,802 tons of miscellaneous freight. The value of the anthracite carried over the lines of the company was placed at $12,503,649; bituminous, $108,502,266, and of coke, $10,-356,060. Fuel for yard locomotives cost $9,081,512 and for train locomotives, $41,-060,682, an increase in both items of $6,773,355. The Pennsylvania Lines consist of over 600 constituent transportation corporations, including five coal-land companies and two coal-land companies classed as inactive. Its net railway operating income was $73,405,325.69, a return of 3.72 per cent upon the investment in road and equipment.

Coming Meetings

The American Wholesale Coal Association will hold its annual convention June 12 and 13 at the Gibson Hotel, Cincinnati, Ohio. Secretary, G. H. Merryweather, Union Fuel Bldg., Chicago, Ill.

Illinois and Wisconsin Retail Coal Dealers' Association will hold its annual meeting June 12-14 at Delavan, Wisconsin. Secretary, I. L. Runyan, Great Northern Building, Chicago, Ill.

Southwestern Interstate Coal Operators' Association will hold its annual meeting June 12 at Kansas City, Mo. General Commissioner, W. L. A. Johnson, Kansas City, Mo.

Pennsylvania Retail Coal Merchants' Association will hold its annual meeting May 23 and 24 at Wilmington, Del. Secretary, W. M. Bertolet, Reading, Pa.

American Association of Mechanical Engineers will hold its spring meeting at Montreal, Quebec, Canada, May 28-31. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

New England Coal Dealers' Association will hold its annual meeting at Providence, R. I., June 13-15. Secretary, C. R. Elder, Boston, Mass.

National Retail Coal Merchants' Association will hold its sixth annual convention June 25, 26 and 27 at Scranton, Pa., with headquarters at the Hotel Casey.

National Safety Council will hold its twelfth annual safety convention at the Buffalo Statler Hotel, Buffalo, N. Y., Oct. 1-5. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

International First-Aid and Mine-Rescue meet will be held Aug. 27-29, at Salt Lake City, Utah.

American Institute of Electrical Engineers will hold its annual convention June 25-29, at Swampscott, Mass. Secretary F. L. Hutchinson, 29 West 39th St., New York City.

International Railway Fuel Association will hold its spring convention at the Hotel Winton, Cleveland, Ohio, May 21-24, Secretary-treasurer, J. G. Crawford, Chicago.

American Society for Testing Materials will hold its annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, N. J., beginning June 25 and continuing throughout the week. Secretary, E. Marburg, Philadelphia, Pa.

The Colorado & New Mexico Coal Operators' Association will hold its annual meeting June 20 at Denver, Col. Secretary, F. O. Sandstrom, Denver, Col.

The Electric Power Club's annual meeting will be held at the Homestead, Hot Springs, Va., June 11-14. Executive secretary, S. N. Clarkson, Cleveland, Ohio.

National Coal Association will hold its sixth annual convention June 19-22 at Atlantic City, N. J. Assistant secretary, C. C. Crowe, Washington, D. C.

Michigan-Ohio-Indiana Coal Association will hold its annual convention at the Hotel Sinton, Cincinnati, Ohio, May 22-24. Secretary, B. F. Nigh, Brunson Bldg., Columbus, Ohio.

West Virginia Coal Mining Institute has tentatively set June 5 and 6 for its annual meeting, to be held at Clarksburg, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

Retail Coal Dealers' Association of Texas will hold its eighteenth annual convention at Galveston, June 11 and 12. Secretary, C. R. Goldmann, Dallas.

The American Institute of Mining and Metallurgical Engineers has accepted the invitation extended by the Ministers of Mines of Ontario and Quebec and by the Canadian Institute of Mining and Metallurgy to hold its autumn meeting in Canada. The meeting will start Aug. 20 at Toronto and end Aug. 30 at Montreal. Secretary, F. F. Sharpless, 29 West 39th Street, New York City.

The Illinois Mining Institute will hold its summer meeting on board a boat on the Illinois River, cruising between St. Louis, Mo. and La Salle, Ill., June 7-9. Secretary, Martin Bolt, State House, Springfield, Ill.

West Virginia Coal Mining Institute has set June 12 and 13 for its annual meeting, to be held at Hotel Waldo, Clarksburg, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 23 NEW YORK, MAY 24, 1923 Number 21

Negation Not Good Publicity

WHATEVER may be the ultimate outcome of the controversy over unionism, how it thrives, expands, contracts and controls, the coal industry must continue to live with the public. At a recent gathering in New York, Lawrence Abbott, of *The Outlook*, remarked that coal is the worst-hated industry in this country today, and no coal operator took exception to this sweeping assertion. One ventured the virtue of the anthracite operators as the reason for such gross misunderstanding of coal; others set it to plain lack of understanding. We venture to note that this lack is no more with the public than with the rank and file of the coal operators themselves.

Put aside for the moment the outstanding men in the industry, both among operators and labor unions, and give thought to the men—numbering thousands among operators and hundreds of thousands among mine workers—who take no part in association or union activities, who do not participate in the national thought of those few who are the reputed leaders of their respective groups. Interest in and knowledge of the larger happenings affecting their industry are subordinated to the immediate problems of the day. Contact with the public is loose and appreciation of the public's attitude toward coal is hazy and uncertain.

The coal operator, whether in the hills of Virginia, Kentucky or Utah, knows that when he has orders, cars and men he can ship coal and he will take almost any price he can get, whether high or low. That is all there is to his business. Give him orders and cars and men not on strike and he performs all that society desires or requires. Until a few years ago there was no question regarding the price, save that from the producer's standpoint it was too low. Car shortages were exceptionally few, national strikes of mine workers unknown, demand was regularly irregular and therefore consistently unsatisfactory. Small wonder then that today's hue and cry over coal is least of all understood by the coal man. Prevent strikes and furnish cars, says the coal operator, and there will be no com plaint by anyone. And he is quite right.

It is right here, however, that the trouble begins. The railroads, it is quite generally understood, are handicapped in their ability to supply unlimited transportation to coal by reason of regulation over many years that has restricted their expansion. The negligence of years is not to be overcome in a day. The LaFollettes and Brookharts preach further restriction. The public alone can decree a more liberal policy toward the carriers, and the public is slow to learn and to give voice to its desire. When railroads were young they were reverenced; now they are too often reviled. The coal industry must do more than blame the railroads for lack of transportation; it must help bridge over the gap until such time as the country may again have transportation in measurable surplus.

Nor will it avail to convict the miners' union of every high crime on the calendar. The railroads are regulated by federal and state officials and by laws that are expression of public opinion, but the United Mine Workers recognizes no law save of its own making. Its creed is simple—More Power; its policy simple—No Reduction in Wage.

There is nothing in the spirit of this land encouraging the belief that organized labor can be controlled in these matters by law. There remains only the organized economic strength of the operators as a bulwark for the safety of the country.

It therefore follows that until the union operators are agreed on a policy and program of united aggressive bargaining with the union of the miners, they have nothing to tell the public; the industry otherwise can but make apologies for that which happens beyond its control.

Prospects in the Export Situation

ON THE whole the European coal situation is becoming easier. It is now quite apparent that Germany has had large stocks on which to sustain her industries throughout the last four months and that although very little coal or coke is being allowed to sift eastward through the French blockade, Germany is not suffering from lack of fuel, as is had been expected that by this time would be the case.

Accounts vary as to the quantity of coke France is getting from the Ruhr. The highest estimates are from English sources, showing 10,000 tons per day, compared with 12,000 tons per day before the occupation. A special dispatch to the *New York Times* dated at Paris May 20 says that the maximum so far received has been 8,000 tons of coke per day. Other figures are lower. At any rate it is becoming increasingly evident that France and Belgium are getting more nearly their needed requirements of blast-furnace fuel. The export demand for coke has fallen off materially on this side and in England as well. Although in January there were 116 furnaces in blast in France compared with but 77 today, production of French iron and steel is gaining and their products are again competing in the Continental market. In Germany, coal prices are receding and German buyers are much less active in the English market. By the end of April there was a congestion of coal-loaded steamers waiting to discharge at the German ports. It is further reported that German buyers of English coal have in recent weeks been reselling purchases made earlier.

There is nothing in the situation today to warrant high hopes of active foreign demand for American coal this summer. True, some continue to anticipate it, but the wish must be father to the thought. As has been noted here in the past, prediction on this score is futile in view of the complications abroad, with much ground for believing that if Europe develops a real want for our coal, it will not be evident until late this year.

Crystallization

FOR generations we have proclaimed that our American civilization was still fluid, that we were always ready to correct the ill-chosen and to root out the inefficient, ready for a second thought to displace a first, if by chance the first was not the best. Insensibly, however, we bind fetters on ourselves while marveling that other nations older than our own are bound by chains of custom and convention.

Of this one cannot but be reminded by the decision of the umpire of the Anthracite Conciliation Board of May 16 that the Hudson Coal Co. must remove the system of checking in and out at the East End, Baltimore No. 5 and Marvine collieries. Doubtless the umpire's decision is perfectly just legally, though he himself probably is quite clear in his mind that practices which are inherently loose and unbusinesslike should be done away with.

He states in his decision that the company has "no right to make any changes without the consent of the other party." Seeing, however, that no changes in the working agreement except to raise wages have been made since 1902, it would seem that the standard of that year has been unduly persistent. With the mine workers demanding all manner of facts from the coal companies, involving weeks of bookkeeping—concessions from them that are not demanded of any employers of labor except the railroads—it seems strange that those employers cannot meet the fabulous statements of the miners with facts based on a knowledge of the hours spent underground. Hardly any employer of labor anywhere is so ignorant of this important element of operation as is the mine operator, and this ignorance has been and is by this decision forced on him. As a result what he knows and can assert qualitatively he cannot declare quantitively and the public, which expects an exact measure in hours and minutes and looks suspiciously at guesses, is little disposed to put any credence in the operator's statements.

Here is a matter that need not be one of doubt. Here is a figure that every company but a coal-mining company can give definitively. What is wrong with the coal operator that he alone cannot give this information which everyone knows is more vital than any other in the settlement of labor disputes? The mine worker quite readily says that in the anthracite region the working time is eight hours when it isn't more, and as the contract calls for hours of that kind for some of the employees the public cannot understand how others of them, not so bound, are leaving the mines after a much shorter period of time. What wonder, then, that it questions the existence of a shorter day which the operator asserts is worked without being able definitely to delimit it!

This is only one of many features that have been crystallized in anthracite operation since 1902 and that tend to become fixed in bituminous mines also. When the contracts are signed smaller matters are brushed aside. The wage becomes the sole consideration, and both sides, as well as the public after a protracted idleness, resent the consideration of any matter, however important, that holds up settlement.

Unfortunately the same public that cannot understand why agreements are a matter for haggling and delay is always disposed to look at the contract when signed and to ask why it did not contain certain provisions and did contain others and to wonder whether the faults of the contract, whether as to wages or conditions, are not the outcome of a sort of treasonable collusion to take advantage of the public. Consequently every effort should be made to incorporate provisions that the interest of the consumer in cheaper coal demands. The Coal Commission has found that the operators have given it all it asks and that the only item it has had denied to it is information as to working time, and that could have been obtained had the union not made every effort to keep it secret.

Less Disturbance, Please

IN ILLINOIS the state teachers' association, perceiving that a tax on coal at the mines might be a source of revenue for increased teachers' wages and for state educational work, are trying to induce the Legislature to levy an 8c. tonnage tax. There really is no likelihood of an 8c. tax bill being enacted. Nobody expects that; not even the teachers. But were the bill amended, reducing the proposed tax to 1c. or 2c. the probability of its enactment would be much greater. That is exactly what will be done if the bill is pushed far enough to be reported out of committee. Then the fight will be on in the House and Senate of the Legislature, and another disturbance will be started in the coal industry.

This case illustrates the old truism that coal is a fair target for any marksman. Here is coal being taken from the ground. From 60,000,000 to 80,000,000 tons of it is mined in Illinois every year. Why not tax it? What a gold mine that would be for the tax diggers of the state! Even 1c. a ton would yield $600,000 a year at least. Two cents would make it $1,200,000. Now if the teachers of the state could only add that $1,200,000 to their salaries! Why not try? It is always easy to raise a popular clamor against the coal barons vividly pictured fattening gluttonously from the shriveling bank account of the abused and helpless public. Why not make the barons pay the $1,200,000?

Would they merely take it away from the people in higher coal prices? Well, let them. It's only 2c. a ton, and anyway a good deal of it would be collected from consumers outside the state, so what do the Illinois teachers care? But the teachers doubt whether the barons actually would be able to raise the price to the people. Wouldn't competition from nearby states prevent that? It can be said to the teachers that large volumes of coal from outside Illinois are sold in that state, some of it in direct competition with Illinois coal. A good deal of this is placed because the Illinois mining companies labor under compulsory regulations covering compensation, safety and the like which add to the cost of production an item far above that of competing regions. Every new law such as the proposed severance tax swells this compulsory cost. The larger this margin, the stiffer the competition from outside coal. So something might be said to the teachers about the goose and the golden egg.

But the main argument just now against taxing the coal of Illinois or Kentucky or any of the other coal-producing states whose legislatures have coal-production tax bills on their dockets, is that the United States Coal Commission is doing its best to find solutions for the complex problems of the coal industry, and if the people of this country want remedies applied they should aid that commission in every way possible. Setting up state disturbances in the coal industry is a poor way to aid. Let all coal tax bills wait.

Mining Methods in the Elkhorn District Conserve the Coal and Retain It in Its Original Purity

Parting Loaded or Gobbed Before Coal Is Shot—Shovel on Boards or Coal Floor—Parting Barred Loose and Both Kerf and Room Ends Swept Clean—Cutting Machines Cleaned and Inspected Daily

By Alphonse F. Brosky
Assistant Editor, *Coal Age*, Pittsburgh, Pa.

THE Elkhorn Division of the Consolidation Coal Co. is now operating fourteen mines in the Elkhorn district of Kentucky, which are better known as the Jenkins-McRoberts plants. Eight of these mines are off the Sandy Valley & Elkhorn R.R. and the other six lie close to the Lexington & Eastern R.R. The openings of Mine No. 204 are at Jenkins, those of Mines Nos. 203 and 205 are on the outskirts of that village. Mines Nos. 201 and 202 are entered at Burdine and Mines Nos. 206, 207 and 208 are at Dunham, the latter two dumping over one tipple. This completes the list of those on the Jenkins side of the mountain. On the McRoberts side of the property are Mines Nos. 210, 211 and 212, which dump over one tipple, and Mines Nos. 213, 214 and 215, which are operated as individual plants.

All these mines eventually will be connected with each other; at present Mine No. 204 connects with Mine No. 207 by an outside tramroad on the Jenkins side of the property, and the latter connects with the workings of Mine No. 214 on the McRoberts side, so that any of the coal, whether near Jenkins or McRoberts, may be dumped on either side of the mountain, and the McRoberts mine, with a minimum of transportation difficulty can obtain supplies from the central shops in Jenkins, which also can make repairs whenever they may be needed.

Most of the 100,000 acres held by this company in eastern Kentucky lies in the Elkhorn field and about 12,000 acres is now under development. With all mines in the division working the daily output is about 10,000 tons. Mine No. 204 is the largest operation; it contributes 1,500 to 1,700 tons of coal each working day.

In the Elkhorn district most of the mining is in a seam of the same name. The coal is excellently adapted for metallurgical purposes, for byproduct coking and for gas-producing, to which uses is put most of the coal shipped. It is interesting here to note that most of the diligent effort exercised in the production of clean coal is exhibited underground, emphasis being laid upon preventing the coal from getting dirty rather than upon cleaning it when it has become mixed with dirt.

Most mines mix dirt with the coal and then employ men or machines to remove it later—if they can. Preventive measures where the coal is unusually clean, like the Elkhorn coal, are better than those which are merely corrective. It would be fair to describe this method as circumventing trouble at its source. All tipples are equipped with screens but, nevertheless, much run-of-mine coal is loaded, as the demand for unscreened coal from the Elkhorn seam is far in excess of that for domestic sizes.

An analysis of a number of seam samples taken at various mines is as follows: Moisture, 1.62; volatile matter, 36.98; fixed carbon, 59.36; ash, 2.04; sulphur, 0.53 (included also in the ash), and phosphorus, 0.005. The heating value of the coal is about 14,619 B.t.u.

In these mines the thickness of the Elkhorn seam varies from 6 to 10 ft., the average thickness being about 8 ft., though in a few places coal 12 ft. thick may be found. The bed is characterized by a shale parting below the center. which varies from a knife

Note—Headpiece shows tipple of Mine No. 214, McRoberts, Ky. The coal is dumped by means of a crossover dump onto shaker screens. The slate is discharged by a kickback dump into an 80-ton slate bin, shown on the left of the illustration, and is then carried to a hillside dump by an aerial tram.

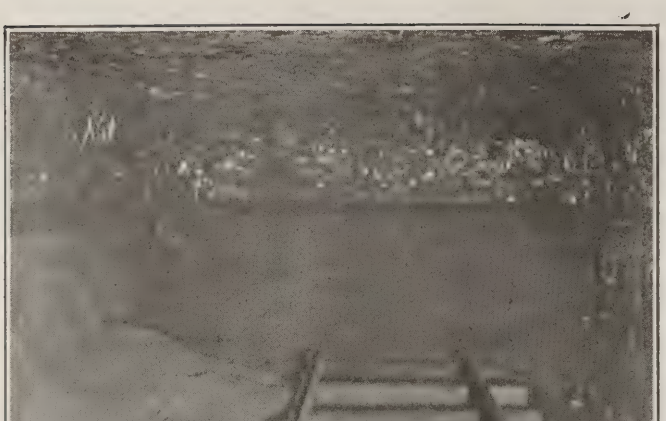

FIG. 1—ROOM ENTRY IN MINE NO. 204, JENKINS, KY.
The parting has been cut by an arcwall machine, the waste material cleaned out and the bottom bench of coal shot and loaded. The parting is of soft shale and usually is from 3 to 6 in. thick. The assertion has been made that an arcwall machine will not cut a straight rib. How about this one? Note particularly the well-squared corners. The cut on the left rib is the first one made in the excavation of a crosscut. Coal is left in the roof, as the high lights on its surface indicate.

edge to a thickness of 18 in. and more rarely of 36 in. Its thickness usually is 3 to 6 in. Because this parting usually is fairly soft, it will break up and mix with the coal unless precautions are taken in the mining, after which it can be separated satisfactorily from the coal by no other means than by washing.

At many mines of the Logan field (West Virginia) most care is exercised in coal preparation on the tipple and less attention than usual is given to preparation or care at the face, while at the mines of the Consolidation Coal Co., in the Elkhorn field, the opposite is true, for in these mines care of the coal at the face is considered highly important. No argument can be based on the difference in the relative reception of the coals from these two fields, for the coals enter different markets. Five seams are mined in the West Virginia field just mentioned, the coals from which in the main are used for general steam purposes and some for domestic use, gas producing and byproduct coking; whereas the Elkhorn coal is used chiefly for the last-mentioned purpose.

The fact that the parting has to be removed in these mines led to the development of the Jeffrey Drennan adjustable-turret mining machine, from which the arcwall coal cutter was developed. For details regarding the cutting of coal in these mines the reader is referred to *Coal Age*, Dec. 20, 1913, p. 926. The arcwall machine is used to do the cutting because only by removing the soft shale parting, then thoroughly cleaning out the cut and sweeping the face and bottom for some distance back before shooting, can a clean coal be loaded into the mine car. As the thickness and the position of the parting in the seam varies from place to place the cutter bar must be adjustable vertically.

About twenty-four arcwall machines, equipped with the latest and improved types of starting box and cutting resistance and carrying a No. 2 all-rubber cable of the concentric type, are used exclusively in the mines of the division. They make a cut 6 to 6½ ft. deep and for the full width of the place, which is in entries 11 ft. and in rooms 12 to 15 ft. wide. One machine has, and will, cut 12,000 tons of coal per month. Yet the machine has not yet cut all that is expected of it. A record of *sixty-two places* in nine hours was attained by a cutting crew using but one machine, whereas twenty-five to forty places are cut daily by each machine, which, when taken on an average for a month's work, yields thirty places per shift.

Often it is said of the arcwall machine that it is not flexible enough in manipulation in a horizontal plane so that it will drive a roadway straight, with the ribs at an even distance. The burden of such complaint usually is attributable to attempts being made to cut places too wide; at other times to the inexperience of the operative.

The arcwall machine can cut a straight-ribbed place, as an inspection of the headings and rooms driven in these mines proves. In fact when the roadway is cut by an experienced runner the ribs are as straight as with any other mining machine. If straight entries, aligned track and a uniform clearance along the walkway in these mines are manifestations of the ability of the arcwall machine to cut a straight rib, then the complaint surely is fallacious.

The more experience a runner has acquired, the quicker will he cut and the straighter will be his rib line. Practice will enable him to set the tip of the cutter bar at the corner between the rib and the face, to sump in under the traction of the truck, to pull the cutter bar across the face by rope and drum until it assumes the exact angle with the lineal axis of the truck to indicate that the correct width is attained, and then to sump out again under traction, straightening the rib line with that of the room or entry. The cycle of the operation is accomplished positively and quickly, with few manipulations, but only after the runner and his helper become experienced in the control of the machine.

Another complaint is that the cutter bar leaves the parting and cuts in the coal. This is not a justifiable complaint, for where such action takes place the machine has been misapplied. Wherever the parting is much harder than the coal containing it, undercutting or topcutting—depending upon the height of the coal and the nature of the roof—preferably should be adopted, so that the coal may be loaded out either in two benches and the slate thus separated, or it may be separated partly at the face after bringing down both benches simultaneously, the refinements of cleaning being accomplished on the tipple. The arcwall cutting machine works at its best in a soft parting such as often occurs in the Elkhorn seam.

At the Elkhorn mines of the Consolidation Coal Co. the machine men cut by contract entirely and agree to keep the machines ready for inspection at any time.

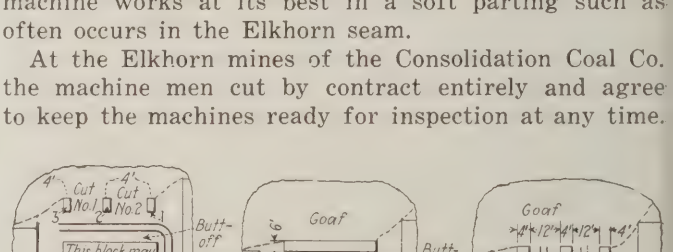

FIG. 2—THREE WAYS OF REMOVING A PILLAR
The first shows the method where the crosscut is so far back as not to weaken the pillar line in any measurable manner. The second shows the same method applied despite the presence of the crosscut. This method is successful if the pressure is not too severe, the coal too friable or the roof weak. The third shows a way whereby the pillar is split by longitudinal roadways from the crosscut. Crosscuts so weaken pillars and interfere with pillaring that one cannot but wonder if General O'Toole does not do well when in an 800-ft. room he burdens himself with but one of them.

By this is not meant that they must maintain the machines in proper repair. They must, however, handle them judiciously and report all troubles. During off-shifts the cutting machines stand in the locomotive barn or under a shed built near the drift mouth. At the close of a shift the machine is returned to its shelter, and consequently the operatives are enabled to use it for riding into and out of the mine.

Upon reaching the surface the crew is required to blow off all cuttings and dust from the cutting machine with air at a pressure of 110 lb., this being supplied by a small compressor unit installed solely for that purpose. Much of the wear on cutting machines is caused by the grinding of cuttings between rubbing surfaces.

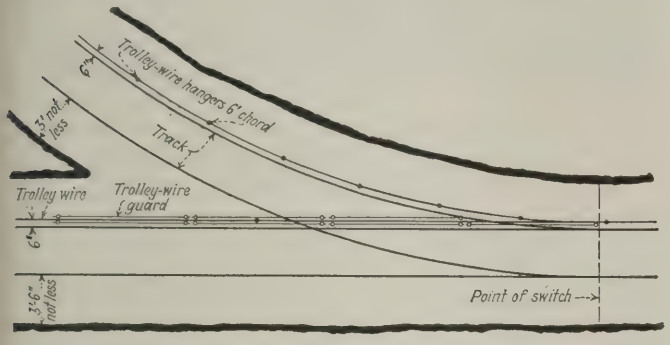

FIG. 3—STANDARD TROLLEY-WIRE PROTECTION
Here the trolley guards are put on either side of the wire where it crosses the branch road. This is a right-hand curve.

Air under a heavy pressure will dislodge all dirt from the exposed surfaces and most of the finer particles from the innermost cracks and crannies. Keep the cuttings off the exposed surfaces as much as possible, and wearing will be minimized on bearings, gears, chains, etc.

The arcwall machines are given a thorough inspection each day by a machine boss or his helper and any defects righted. This accounts for the continuity of service, which is further demonstrated by the low cost of upkeep.

Coal is mined by the room-and-pillar multiple-entry system. Entries are driven 11 ft. wide on 35-ft. centers. The main entry consists of two haulageways, a manway, and two airways on either side which serve as intake, making a total of seven entries. The large sectional area thus provided to the splits permits of a low velocity in the ventilating current. At intervals of 1,400 to 2,200 ft., depending upon conditions, cross-entries are turned from the main entries, and the panels thus formed are developed separately, being isolated from adjacent panels by barrier pillars.

Rooms Driven Narrow Save Row of Timber

The cross-entry consists of two haulageways and an airway which may be either on the right or the left depending upon the territory to be developed. As many room entries are driven off the cross-entries as the crop line will permit. Barrier pillars along the main entry are 200 ft. wide, and those on the cross-entries are about 175 ft.; barriers also are left under the streams on the surface.

After years of experimentation the company concludes that in recovering the Elkhorn seam the narrow room with a length of 200 to 300 ft. gives the best results. Rooms of different widths were driven in some places as a means of determining definitely which cross-section would provide the most ready and economical

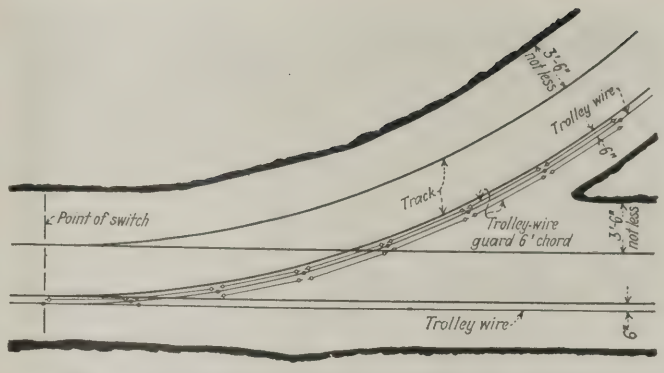

FIG. 4—STANDARD TROLLEY-WIRE PROTECTION
Trolley guards are put on either side of the wire where it crosses the main road. This shows a left-hand curve.

mining. High coal and a roof not too strong make a narrow room necessary. A room no wider than 15 ft. yields the best results. Specifically, a 12-ft. room is favored, for those driven any wider usually must be timbered.

Three representative systems of room layout which have been tried experimentally in these mines now must be mentioned. The first system provided for a 22-ft. room with a center track and with rows of posts on 5-ft. centers on either side of the roadway. Later a 15-ft. room was tried with one row of posts opposite the side from which the pillar is drawn. These posts are placed 30 in. from the rib and 22 in. from the track on 4-ft. centers, though they may be placed as close as occasion demands. The cap piece used is 2 in. thick and 18 in. long. In these wide rooms refuse from the parting and that incidental to preparing for the next cut could be, and was, gobbed.

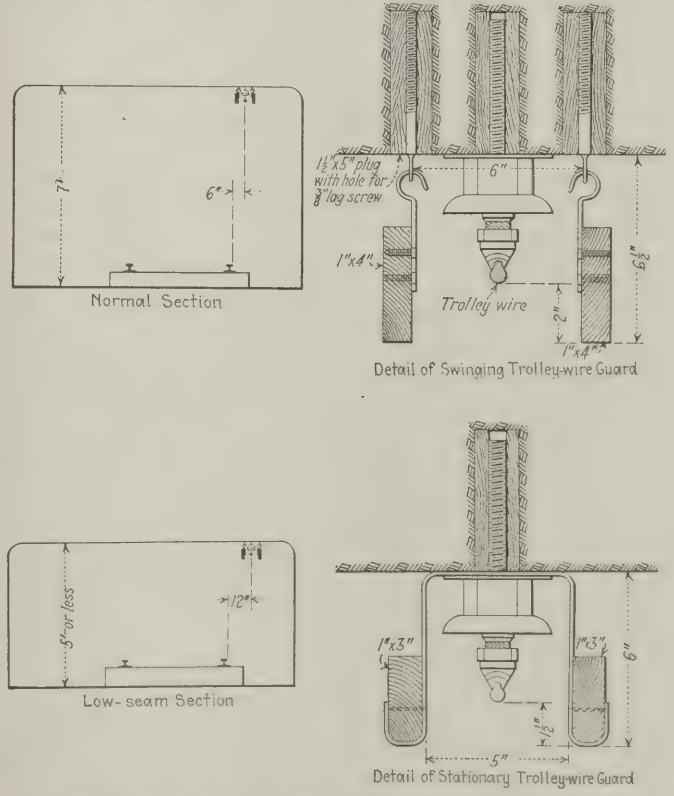

FIG. 5—METHOD OF HANGING GUARDS AND WIRE
The rules of the company say: "All places where men are compelled to pass under the trolley wire should be protected with guards. Trolley wire should be hung 6 in. from the outside of the rail. In low places this can be increased to 12 in. Where the track is straight and level, trolley-wire hangers should be placed every 15 to 20 ft. On curves of 63-ft. and 112-ft. radius, one hanger should be placed every 6 ft. Where the top is irregular additional hangers should be used to maintain the trolley wire at uniform height."

FIG. 6—REMOVING PILLAR FROM A 12-FT. ROOM

The road curving to the right is entering a buttoff, the fourth so far made into the pillar of this room. That there is pressure can be seen by the thin slab of coal to the right of the illustration that has slid to the track. Still conditions are favorable for a good recovery, for the fall in the gob is a good one and comes up to the wing pillar of the buttoff, which is 6-ft. wide. Note how little can be seen in this illustration of the clay parting in the coal.

It was discovered thereafter that a 12-ft. room is easier to keep in condition than wider rooms. The present systsm, based on 12-ft. rooms located on 50-ft. centers, is best because the rooms are easily cut, the top stands well and from all other points of view it makes an excellent working place.

In the event that there is not enough coal in a 12-ft. room to accommodate a diligent loader, the width is increased to 14 or 15 ft. in order to give him enough work; but after the width exceeds 12 ft. a row of posts must be set and as much refuse as possible gobbed in the room.

All fines from the refuse produced in cutting entries and rooms is thrown on the track; the larger pieces coming both from entries and from the narrow 12-ft. room is loaded into mine cars and hauled to the surface. Where seventy-five loaders are engaged each day about eighty cars of refuse are taken from the working places to the waste dump. This means that before the coal is shot at a working place 12 ft. wide, about one car of refuse is loaded out, all of which comes from the parting, for the roof does not scale, being protected by a thickness of coal which is left there for the support of the drawslate. As a place such as this yields approximately fifteen tons of coal per cut, about one car of refuse for each six cars of coal is taken to the surface. In the wider rooms already mentioned the refuse is gobbed, as is also that incident to pillar drawing.

The management furnishes each working place with a scraper, a punch bar and a broom. After cutting with the machine, the miner with the flat scraper and the punch bar cleans out the cut, punching out all overhanging and underlying shale on the top and bottom of the cut. After loading out the refuse into a mine car he thoroughly sweeps the cut, the face and the floor for a distance of 6 ft. from the face, to provide a clean table for shoveling the coal after it is shot down.

Wherever the bottom is soft, boards are laid across the working place, and the coal which rolls out is shoveled from the platform thus formed. Under such conditions the bottom holes are bored high enough to permit leaving a ply of coal 4 to 6 in. thick from which the loader shovels. After the bottom and top benches are loaded out this bottom slab is taken up carefully. The lumps are thrown into the mine car, and the fine coal shoveled on the truck as refuse.

The lower bench is shot and loaded out first and the upper bench last. Two holes in each bench are drilled 12 to 14 in. from the rib. Safety props need not be set during the loading of the lower bench as the shooting is so well regulated and the coal so solid that the upper bench hangs unsupported; in fact, this coal has been known to hang for years.

Unless the roof of shale is protected from the air, to which it is markedly susceptible, it is held only with difficulty; otherwise it will spall and flake badly. Consequently 10 to 14 in. of coal is left in the roof on the entries and about 12 in. in the rooms. This holds the roof securely in most cases, though where the roof coal comes down on the haulageways, at turnouts especially, steel timbering is applied immediately. In the retreat about 8 in. of this coal is lost, which is unfortunate, as it is of the same quality as that which is recovered.

In order to be sure that all cuts are properly cleaned, all blasting of the coal is done by a shot foreman who makes a careful inspection of the cut, the face of the coal and the bottom. If the work is completed as prescribed by the company and the holes are correctly drilled, he loads and shoots them. Monobel No. 5 is used as an explosive and is fired by an electric detonator with a small magneto battery.

Samples, taken monthly at the face of each working entry, are sent to the laboratory of the company, where accurate analyses are made; and from time to time samples are taken from the coal at the tipple in order to check the care with which it is being prepared.

Several methods of pillar drawing have been tested, among others slabbing, drawing on the advance and drawing on the retreat. Pillars are pulled retreating except in some few sections where a system is already established necessitating pillar drawing on the advance. The former method has been adopted as standard because it is the most economical and safest.

Pillars are brought back generally by butting-off with a place 12 ft. wide (equal to the width of the room), leaving a wing rib 3 to 6 ft. wide toward the gob. In excavating this buttoff and in other pillar work no coal is left in the roof, contrary to the custom in

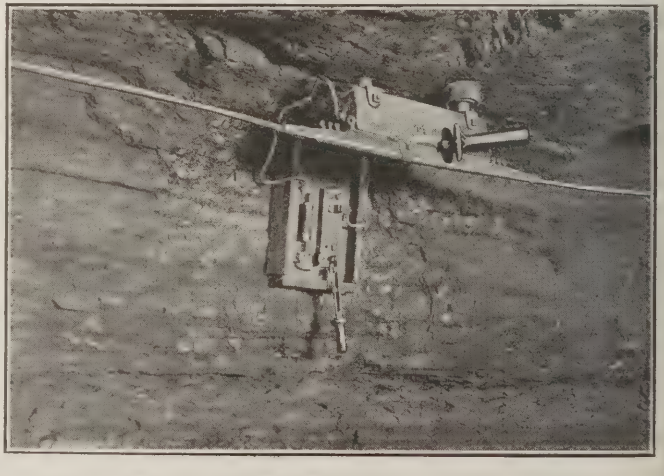

FIG. 7—FUSES PROTECT POWER LINES AT NIGHT

During the day a section needs plenty of power for mining machines and locomotives. Should a wire fall and a short-circuit occur, a fire might be started, but there would be men nearby who could cope with the trouble. At night, however, it might not be so. Consequently the line switch is thrown and a fuse switch, which will melt if more than 60 amperes is passed through it, is used to protect the current. Note the size and character of the shale parting.

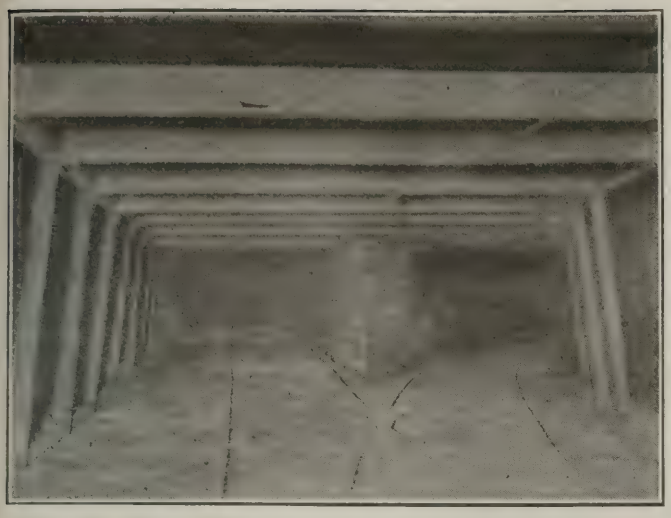

FIG. 8—STEEL SETS AT TURNOUT, MINE NO. 201
The longest of these beams is 20 ft. These are standard sets made of 12- and 6-in. I-beams on 5-ft. centers. Note the strength of the concrete pier, which is faced on its edge with two rails.

driving rooms and entries. On the other hand about 8 in. of coal is left in the roof above the rooms and entries in the retreat. If the roof load is not excessive a 6-ft. wing is butted off. Then a machine cut 12 ft. long is made through that half of the wing farthest away from the working room, leaving a 4 x 6-ft. stump to be drawn by hand picks.

The second cut of the same length is made between two 4 x 6-ft. stumps, thus completing the extraction of that wing as in Panel A, Fig. 2. Usually the same method is continued toward the entry. Sometimes a thinner wing is split from the pillar. If possible, the narrow pillar, approximately 3 ft. wide, is cut by the machine, but wherever the roof will not permit of machine cutting the wing is drawn by hand picks.

About twenty split posts are used in each cutoff, only a portion of which are recovered. The loss of steel is small. In the rooms 30-lb. and in the buttoffs 20-lb. rail are used. Short jumper lengths are placed in the butoff beyond the curve so that the track may be more readily torn up on the retreat.

If the pillar between the fall and one of the crosscuts driven on the advance is approximately 24 ft. wide and roof is fair, the block may be butted off, developing wings on each side, both of which can be brought back together as in Panel B, Fig. 1. If, however, the roof is bad the block may be worked from the breakthrough by driving two subrooms bounded by subpillars 4 ft. wide, as in Panel C, Fig. 1.

In driving entries track is laid on the advance in alternate crosscuts. These are closed by doors. The other crosscuts are sealed with permanent stoppings. A row of posts is carried up the center of all room and entry crosscuts whether they are closed by brattices or stoppings, except, of course, those laid with track. This is done to keep up the roof and insure an open place in case the pillar when being extracted has to be split. Usually these props are not recovered.

Ventilation at the larger mines is accomplished by a 14 x 5-ft. fan belt-driven by a 150-hp. alternating-current motor. This fan is set in a brick building with a fan casing of brick and steel, which is provided with reversible doors and protected by light explosion walls which form part of the air conduit to the mine. The fan speed, being fixed by the size of the pulley on the motor, always is constant except when starting.

Like all other high-volatile coals, that from the Elkhorn seam ignites readily, so extreme care must be taken to prevent mine fires. A number of years ago the company had a fire in one of its mines, which caused it to adopt as a fixed ruling the requirement that all mines must be equipped with a fuse switch in conjunction with the line switch. During the day's run, while all men are working, the line switch is closed; but during the off shifts this switch is opened and the circuit closed through a fuse switch. A Buss shellacked fuse with a capacity of 60 amp., furnished by the Bussman Mfg. Co., of St. Louis, is found well suited for the purpose. If, because of a roof fall, the line is knocked down the circuit is broken by the blowing of this low-amperage fuse, before the line can set fire to the coal on the floor.

Where loose roof is encountered along the entries steel sets and beams are applied in a manner best suited to the local need. In one place I found sets of steel on 6-ft. centers composed of an 8-in. I-beam cap resting upon 4-in. I-section legs of the batter type. Sometimes straight legs are employed but batter legs have the preference. These timber sets are strung with two courses of locust posts and filled to the roof with similar material. Where the timbers are not protected by a concrete wall they are braced with 6 x 6-in. oak.

In another place, at a turnout, 60-lb. rails on 3-ft. centers are used to support the roof. Hitch posts in either rib rest on the lower bench of the coal just below the parting and support the rails, of which there are thirty-five, varying in length from 12 to 24 ft., and strung with split-timber lagging. Posts are set in both ribs, which procedure is unusual, for at most coal mines where hitch posts are used only one hitch post is employed for each cap. Both posts, being of the same length and supported on the same coal surface, settle gradually and equally under the load imposed on them.

At another turnout nine sets of steel timbers made up of 12-in. beams for caps and 6-in. sections for legs are set up on 5-ft. centers. These are braced between by heavy oak at both the top and the bottom. The roof above these sets is high, and in consequence cribbing has been built to the roof above a course of 3-in. lagging. The corner of the concrete pier at this place is faced with two 40-lb. rails and the concrete likewise is reinforced with scrap iron. Sometimes 10-in. beams and 5-in. legs are used at turnouts where the roof is stronger than that at the place just described.

Ford Paid $2,783,000 For Kentucky Land; Now About Ready to Build Railroad

All speculation as to the price paid for the Peabody Syndicate coal-land holdings in eastern Kentucky came to an end last week when the Fordson Coal Co., in answer to interrogatories in the T. C. Fuller suit to set aside the sale, showed that it paid $2,783,000 for the 120,000 acres, including interest from Jan. 1, 1923, to March 17, when the option was exercised, the real value having been $2,750,000. Previous estimates of the sale price ran as high as $15,000,000. Fuller had claimed a share and demanded an accounting on the ground that the price was higher than had been announced.

Maysville on May 3 reported that surveyors had completed a survey down Brush Creek in Ohio to the Ohio River, opposite that town, and advised farmers not to plant crops on the survey this year. This is the route which it is believed will connecte the Detroit, Toledo & Ironton, the Ford railroad, at Maysville, with a branch line of the Louisville & Nashville into the southeastern Kentucky coal fields.

How the Law Shaft Is Protected Against High Water

Ideal Arrangement Is to Put Pumps in a Shaft of Their Own, Making Pipes the Only Connection with the Mine — Law Shaft Has Slope Sealed Against Workings, Giving 66,000,000 Gallons of New Storage

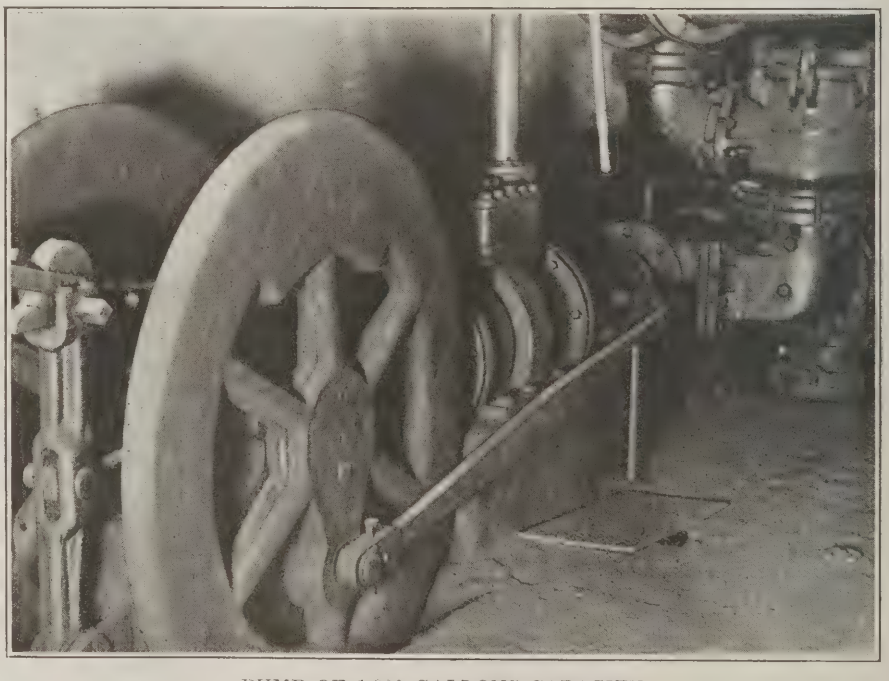
By Dever C. Ashmead
Kingston, Pa.

IN AN ADDRESS before the Engineers' Society of Northeastern Pennsylvania, H. H. Kudlich, superintendent of the Jermyn colliery of the Hudson Coal Co., outlined the difficulty experienced at that mine during the flood period in June and July, 1922, which, however, it may be said, did not differ materially from the difficulties that have had to be contended with at many times in numerous collieries in the anthracite region.

When a mine becomes flooded, the water often rises in the mine workings more rapidly than the pumps that have been installed can remove it, and as they are stationed near the lowest point in the mine, it is not long before they are under water and, in consequence, cannot be operated. For this reason auxiliary pumps have to be installed to remove the water that has accumulated from the flood.

In many instances the water in times of heavy rainfall has risen two hundred or more feet in elevation, and a volume of water has accumulated that can be measured only in billions of gallons. Before operations can be resumed water has to be removed, and as the main pumping plant has been flooded it cannot be used until almost all the water has been removed from the mine and the pumps put in condition for operation.

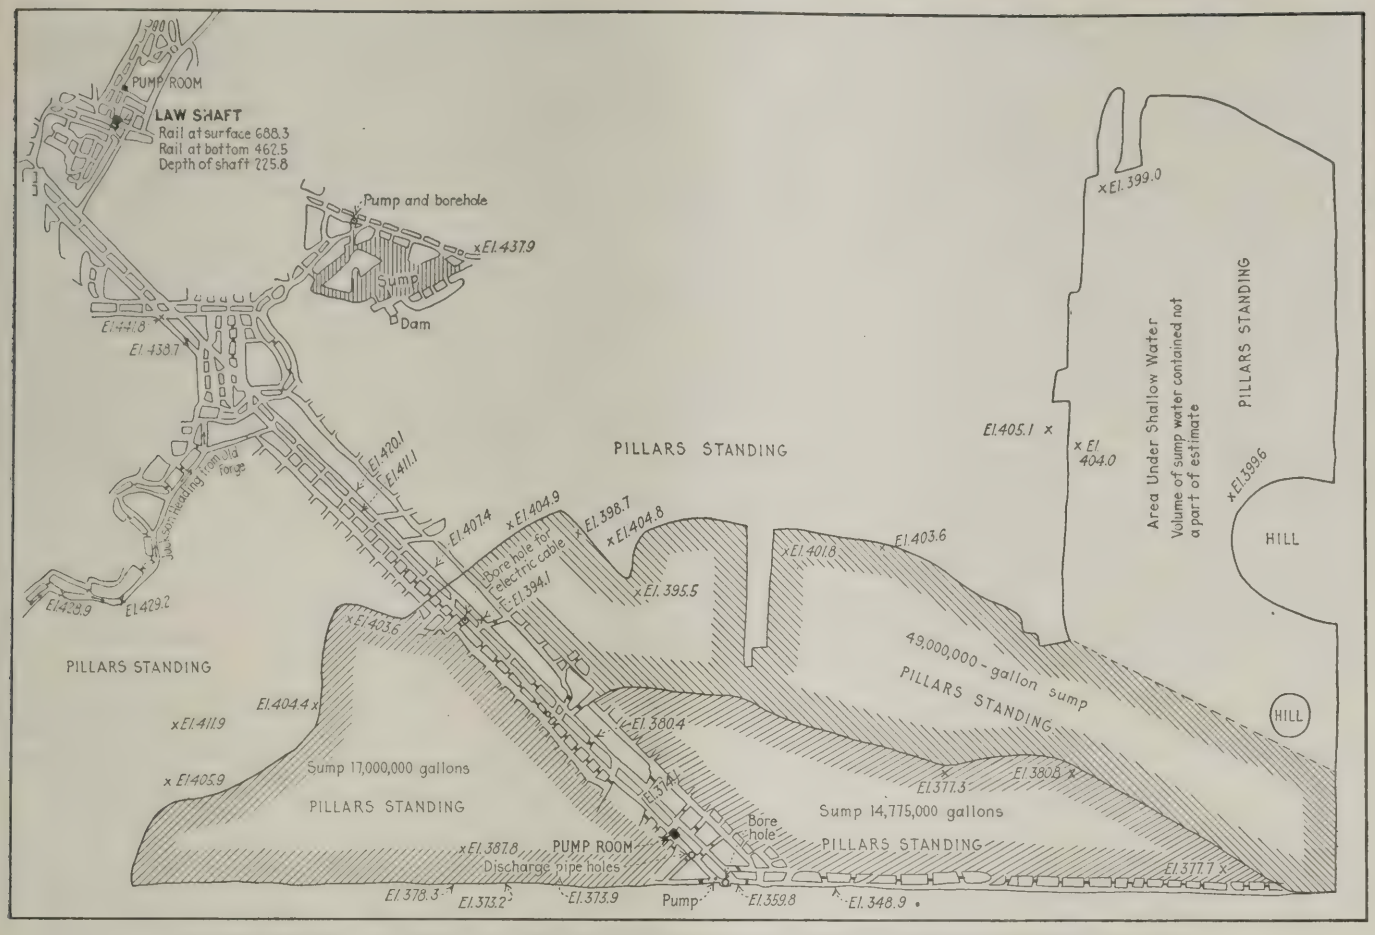
The question has arisen in the minds of many operators whose mines are subject to flood conditions, Is it possible to so design pumprooms that they will not be flooded in times of high water? This, indeed, is possible and has been done successfully in the anthracite region in three instances to my knowledge.



The best and safest method of constructing such a pumproom is to sink a separate shaft or slope to the point where the pumproom is to be located. If it is in the rock it is safer than if it were in the coal. Then the only connection from the pumproom to the workings should be by the pipes by which the pumps receive their water. Where such a provision is made, practically no water can enter the pumproom except through the proper means of entry, the intake pipes of the pumps. This permits the pumps to be operated no matter how badly the mines are flooded.

If this is impracticable, however, then the next best method is to use an old slope in the mine. The pumproom would be placed at the foot of this slope, and all openings into the mine would be sealed off by means of dams. This would prevent the water entering the slope or the pumproom. If the mine were deep, however, then a point would be reached where the head of water possibly would be too great for the safety of the pump runners in the pumproom, for the dams might fail and let in a deluge.

Though in this case it would be necessary to abandon the pumps before the failure took place, the chances are that the dams would hold, and when the water receded to a point at which it would be safe for the men to work, the pumproom could be re-entered and, the pumps being entirely uninjured, they could be started without any delay. They would then be able to assist in the lowering of the water. In many operations, however—even in case of a flood—the water would not rise in the mine above the danger point on the slope, and the pumps could be continuously operated, thus rapidly lowering the water in the mines. This is particularly true where the mines are shallow and subject to flooding and where the measures are flat and the water can spread over a large territory without any great increase in height.



The Pennsylvania Coal Co. has made a careful study of the construction of "concealed," or submersible, pumprooms and has two of them at its operations. One of these, which is located at the Law shaft of the Central colliery near the town of Old Forge, Pa., will be described in this article.

Law shaft, No. 13 shaft of Central colliery, No. 1 and No. 2 shafts of Old Forge colliery and the Sibley shaft are all interconnected underground, making an immense

PUMP OF 1,000 GALLONS CAPACITY

This pump is of Dunmore type and is one of those in use at the Law shaft. Flywheels help the steam to maintain an even pressure on the water throughout the stroke. Some pumps of this type are used in the main pumproom at the foot of the shaft, in the old slope and at No. 2 Old Forge colliery but not in the submersible pumproom, to which, indeed, steam is not taken.

SUMP SYSTEM AT THE LAW SHAFT SHOWING AREA AVAILABLE FOR WATER STORAGE

All over the area shown pillars are standing, some near the shaft having been packed with rock. The level of the water at the lowest pump is about 360 ft., yet the water can rise till it reaches an elevation of about 400 ft. before that pump is drowned. It might not be safe to work around the pumps when under such a head, but at least they will be protected so that they can be started as soon as the water has been lowered to a point that is sure to afford safety, and, furthermore, the pumps can be arranged so as to operate continuously without attention. Of course, provision would have to be made for pumping out of the pumproom any water that might seep through the walls or floor for in a submerged room there is no place where water can drain.

area of communicating workings. The lowest of these are in the Law shaft, and naturally most of the water that is produced in these collieries could drain to this point. Part of the water, however, is collected and pumped to the surface from the pumprooms established at each of the different shafts.

In case of a flood the workings in the Law shaft would be completely flooded and the usual difficulty would be encountered in using portable pumps or pumping arrangements for dewatering the mine in case of a flood. Further, if no arrangements were made to handle the water that would collect in the lower workings it could easily rise to a sufficient height to drown out the main pumping room at the foot of the Law shaft.

In the past the water has risen until it was 3 ft. deep in the pumproom. If arrangements had been made so that the pumps in the lower levels could be operated during such inflows of water, the water level in flood periods could be kept at such a point that the water could not drown out these pumps, which are those having the greatest aggregate capacity.

In order to realize the quantity of water that has to be handled in periods of flood it may be well to enumerate the number and capacity of the pumps that are now in place in these collieries. The main pumproom, which is at the foot of the Law shaft, contains one Aldrich triplex pump with a capacity of 1,000 gallons per minute and driven by a 120-hp. motor, two Jeanesville centrifugal electric pumps, one with a capacity of 1,000 gallons and one with a capacity of 700 gallons, one Scranton pump with a capacity of 1,000 gallons, one Dunmore steam pump with a 1,000-gallons capacity, two Dunmore steam pumps each with a capacity of 1,469 gallons and one Scranton pump with a capacity of 2,000 gallons, or a total capacity of 8,939 gallons per minute.

Down in the old slope from the Law shaft is one 1,000-gallon Dunmore pump. At the No. 13 shaft of the same colliery are two old Cornish pumps having a capacity of 800 gallons each, and also one 1,000-gallon centrifugal pump. At the No. 2 shaft of the Old Forge colliery there is one 1,000-gallon Dunmore pump, two Scranton steam pumps of 1,800 gallons capacity each, and one new Barrett Haentjens electric centrifugal pump having a capacity of 2,500 gallons. At the No. 1 shaft of the same colliery is an 800-gallon Cornish pump. At the Sibley shaft are two Scranton centrifugal pumps pumping against a head of 300 ft. with a capacity of 1,800 gallons each.

This makes the total pumping capacity of the different pumprooms 24,038 gallons per minute. This capacity was not considered sufficient for protection against floods, so it was decided to establish another pumproom down the new slope from the foot of Law shaft. In this pumproom were placed two 1,500-gallon Allis Chalmers electric centrifugal pumps. These pumps worked against a head of 325 ft. This gave a total capacity of 27,038 gallons per minute for the colliery.

As it would not be difficult to drown out these pumps by flooding it was decided to make a concealed, or sub-

mersible, pumproom in which to place these new pumps. In the first place, all of the openings on the left-hand side of the slope were sealed by dams to a point about 750 ft. from the bottom of the slope. This made a sump that had a capacity of 14,775,000 gallons. Then it was decided that it might be advisable to seal by dams the three openings above these on the slope, which would increase the capacity of the sump to about 49,000,000 gallons.

If the twenty-two openings on the right-hand side of the slope were sealed, it would further increase the storage capacity by about 17,000,000 gallons, giving a total capacity of 66,000,000 gallons. This would store all the water received by the mine in 24 hours and not evacuated by the pumps, should the flood bring in 72,000 gallons per minute. It is probable that the pumps at the foot of the slope would greatly exceed their rated capacity, for the flooding would cause the water entering the pumps to be under a heavy pressure, thus lowering the actual lift. When the water reaches the height at which it will enter the slope and run down to the pumproom its free surface will be about 40 ft. above the pumps.

In order that the water might flow freely from the Old Forge colliery to the Central colliery the ditch in what is known as Jackson's heading was cleaned, and the water can be run directly into the sump at Law shaft. Not only are there these large new sumps in which to store water but there still remain the old sumps and these could hold back a large quantity of water. By this arrangement the danger of flooding is materially reduced.

Colleges Offer Summer Mining Courses

IN THE summer months the coal mines run only irregularly, and the short summer mining courses afford to men who desire to acquaint themselves with the science of mining an excellent opportunity to do so without losing many actual working days. Most of the mining schools have short courses arranged to accommodate those who are willing to make the slight sacrifice. The course usually lasts from a month to six weeks, and it is sufficiently long to enable a man to prepare for the mine foremen's examination and to fit him fully for the duties he must perform while acting in that capacity, not only from a safety and hygienic point of view, which is the state's concern, but from an economic point of view as well.

SOME OF THOSE TAKING THE SHORT MINING COURSE AT WEST VIRGINIA UNIVERSITY, 1922

A. C. Callen, professor of mining, is fourth from the right in the second row from the bottom. In 1922 there were 69 scholars and in 1921, 106.

MINE RESCUE TEAM AT SHORT MINING COURSE, WEST VIRGINIA UNIVERSITY

These men were trained by the West Virginia Department of Mines and are shown wearing their mine rescue equipment.

In fact, it is somewhat generally conceded that the mine foremen's examination is not comprehensive enough and should embrace first aid, mine-rescue training and enough mapping to prove that the would-be foreman is thoroughly competent to read a mine map. Perhaps the fact that many mine inspectors are not trained in first aid and mine rescue is a reason why examinations do not in any way cover these necessary requirements. It is quite probable that before many years no new mine inspectors will be appointed who have not taken at least the short mining course. It is quite conceivable, in fact, that the requirements as to academic training may be made more drastic, but this small concession to the importance of having such a grounding in the art of mining as training at a college confers doubtless will be required.

Those who have attended some such course will be enabled to find out whether they are mentally qualified and psychologically inclined to take the longer course of training that will fit them for the superintendency. The industry is not going to be content much longer to accept for the highest positions men who do not know the fundamentals of mechanical and electrical mining engineering and who consequently must rely entirely on the expert work of others.

As it is now the superintendent often is so grossly lacking in the elements of both these essential branches of a mining education that he cannot even understand the advice of those whose work it is to formulate plans for the conduct of the mechanical and electrical details of the plant. They use what is to him an unknown tongue. Certainly the least we can ask of the superintendent is that he shall learn to understand what they say.

But this is getting somewhat apart from the main subject—that of the shorter mining course. The School of Mines of Pennsylvania State College holds a free course for bituminous and anthracite mine workers from June 25 to July 28 of the present year. This is five weeks of study, but if the student cannot spare that length of time he will be welcomed for four. The first week, June 25 to June 30, will be devoted to mine safety work. In this period there will be 30 hours of intensive training in this important subject, which, as

Airplane View, Pennsylvania State College

This university — for such it really is —has an excellent School of Mines presided over by E. A. Holbrook, for a while acting director of the U. S. Bureau of Mines. It is an ideal place for a summer course in mining as it is on the high ground of the Appalachian Mountains where the student will escape much of the overpowering heat that is so distressing to those who are accustomed to be in the cool of the mines during the heat of the day. *(Courtesy U. S. Army Air Service)*

has been said, should be understood by every fireboss, foreman and inspector. Thereafter the work will be divided as shown in Table I. There will be courses for beginners and for those capable of taking more advanced studies.

TABLE I—FOUR WEEKS CURRICULUM AT PENNSYLVANIA STATE COLLEGE

Preliminary Course		Advanced Course	
Study	Hours	Study	Hours
Mining law	24	Mining law	24
Mine gases	18	Electricity in mines	12
Safety lamps and gas detectors	20	Advanced mine ventilation	12
Mine fires and explosions	6	Fan testing and ventilation practice	20
Mine ventilation	30	Use of explosives	5
Mine drawing and mapping	20	Choice of mining methods	5
Explosives	5	Timbering	5
Mining methods	10	Pumping, hoisting, haulage	12
Mining machines	5	Mine management	12
Timbering	10	Surveying	40
Total	148		147

The figures in Table I are minimums, and men who desire to spend more time in obtaining greater proficiency in certain lines will be given the opportunity. Night study will be expected. The Bureau of Mines safety car will be at the college to assist in the safety training work of the first week. Provision has been made for training teachers, and a special certificate will be given to those qualifying for this work.

The school has a 300-ft. tunnel with three steel mining fans of different types, a Clifford lamp-testing gallery, the most complete safety-lamp exhibit in the world, a smoke room, oxygen apparatus and gas detectors, mine and breaker models, an air compressor and a great variety of drills. Any man may enroll who has had at least one year in practical work in or around the mines. On completion of the five weeks' course a certificate will be awarded showing subjects studied and another will be given to those who have attended the full course for two years.

Lodging costs from $2 to $3.50 per week and board from $6.50 to $7. The location of State College, in a beautiful country town 1,200 ft. above sea level, where the air is cool and bracing, makes the opportunity attractive. Studying is a pleasure under such conditions, and the trip will prove to be a vacation rather than an unpleasant duty.

E. A. Holbrook, dean of the school, was for many years a leading official in the Bureau of Mines and for a while acting director. Apply to him and make all arrangements. At the close of the course the state will hold examinations for mine foremen and firebosses, July 27 and 28, at Tyrone, Pa., and at some point in the anthracite region.

A summer mining school will be held also by the Carnegie Institute of Technology, Pittsburgh, Pa., June 25 to July 20. This will be a single course only. The classes in the morning will be held in the Institute, when the subjects will be mine laws and regulations, mine ventilation, mine gases, safety lamps, methods of working, mine explosives, mine timbering and mine haulage. The afternoon classes will be held at the U. S. Bureau of Mines, the subjects being mine-rescue and first-aid training and mine safety. Demonstrations will be given at the Experimental Mine to exhibit the action of coal dust and the use of permissible explosives.

The fee for the course is $12. Students can live at home or obtain a room in a dormitory of the Institute for $2.50 a week, meals being purchased at restaurants close by. More information may be obtained by addressing the Supervisor, Co-operative Department of Mining Engineering, Carnegie Institute of Technology, Pittsburgh, Pa. Only twenty-five men will be accepted. The Institute will award certificates, as also will the U. S. Bureau of Mines, each in its respective field.

The department of mining of West Virginia University, Morgantown, W. Va., which limped along with a beggarly three students in its summer course of 1913, 1914 and 1915, which had only eight students in 1916 and fell back again with a dull thud to four in 1917, has in recent years received all manner of support, reaching to 106 students in 1921 and 69 students in 1922, and in 1918, 1919 and 1920, 23, 57 and 68 respectively. A. C. Callen is particularly well fitted for the matter in hand, having a remarkable enthusiasm for this kind of service. This course lasts six weeks, from June 11 to July 21.

At the close of the course the State Mining Department will conduct an examination for mine foremen and firebosses. The subjects are mining arithmetic, explosives, methods of working, timbering, mine gases, electricity in mines, drainage and pumping, mine ventilation, haulage, mine fires and explosions, first aid,

mine management, mining machinery, drawing, safety lamps and mine-rescue work. The instruction in first aid to the injured and mine-rescue training will be in charge of the West Virginia Department of Mines, and under the personal direction of Robert Lilly. No more than twenty-four men will be in a section, consequently each man will receive all necessary attention. The tuition is free. Books and supplies will cost less than $2, and board and lodging will be about $8.50 per week.

There are no entrance requirements or residence rules. Anyone engaged in mining who can read and write English and who really desires to advance himself in the industry will be welcomed. The course is given primarily for West Virginians, but arrangements will be made to take care of a few students from outside the state.

The staff of instruction comprises A. C. Callen and C. K. Brown, of Morgantown; Adam Crawford, of Fairmont; William Norris, Jr., of Welch; E. E. Criswell, of Beckley; L. C. Hutson, of Mount Hope; J. P. Madden, of Logan, and J. H. Haskell, of Montgomery. Further information may be obtained by addressing the Department of Mining Engineering, West Virginia University, Morgantown, W. Va.

The School of Mines of the College of Engineering of the University of Alabama, University, Ala., will hold a four-weeks summer course in mining, June 4 to June 30, which will give an exceptional opportunity to those who desire to pass state mine examinations. The subjects taught are listed in Table II.

TABLE II—FOUR WEEKS CURRICULUM, UNIVERSITY OF ALABAMA

Study	Hours
Alabama coal-mining law	18
Geology of coal and mining methods	18
Electricity, haulage, hoisting, pumping and mine machines	18
Practical mathematics	24
Drawing and study of mine maps	18
Mine gases, ventilation, fans, safety lamps and safety	18
Mine-rescue and first-aid course given by U. S. Bureau of Mines (optional)	20
Total	134

Special provision will be made for advanced work for those desiring to go further. A certificate will be given to each man showing the subjects taken and the credit received. The instruction is given without charge. Lodging at the university or in Tuscaloosa will cost about $2 per week. Board will cost from $5 to $6.25 per week. The U. S. Bureau of Mines, Southern Experiment Station, which is located at the university, will assist in the training. The university is only one mile from Tuscaloosa and can be reached by street car. H. D. Pallister, professor of mining engineering, is in charge of the courses and further information can be obtained from him.

At the University of Kentucky the short mining course is not given during the summer months but during the last half of the second semester of the regular college year. The course this year opened April 2 and will close May 26, lasting eight weeks. The number of men attending the course varies from year to year and ranges between 30 and 70, depending upon conditions prevailing in the coal field. The number attending this session is 30, but it usually runs between 40 and 50.

C. J. Norwood, head of the Department of Mines and Metallurgy and professor of mining, writes, "I am under the impression that the course given here for 'practical miners' was the first course of the kind established in any of the state universities or state colleges. It was established, at my request, by the board of trustees of the Agricultural and Mechanical College (now the University) of Kentucky in 1907, at a time when mine foremen did not have to be certified in this state."

Like most of the others this is a free course. It grants a certificate to every man who takes the instruction. The studies are arithmetic, mine layout, blasting, timbering, shaft and slope sinking, ventilation, drainage, mine gases, safety lamps and testing, explosions, mine fires, rescue and relief, surveying and map drawing and Kentucky mining law.

It may be added that the School of Mines of the University of Pittsburgh, not desiring to enter into competition with or duplicate the work of the Carnegie Institute of Technology, does not hold a summer school.

Building a Town for a Mountain Community

G. W. HAY, general manager of the Consolidation Coal Co., Elkhorn Division, at Jenkins, Ky., calls attention to the fact that two provisions for making the Elkhorn district self-sufficing were a hospital and a dairy, facilities that should not be overlooked in the creation of any group of mining villages. These items were omitted in an article entitled "Building a Town for a Mountain Community," in which were described the social developments at Jenkins and McRoberts. The

HOSPITAL OF CONSOLIDATION COAL CO., AT JENKINS

Set in the woods and facing, from spacious sun porches, Elkhorn Creek, the Elkhorn Hospital affords an opportunity for the early convalescence of the sickly or injured members of the Consolidation's villages in Kentucky.

illustration herewith shows the hospital. It serves not only for the care of the families of the mine workers but for the needs of others not in any way employed by the coal company.

About two miles from Jenkins along Elkhorn Creek is the dairy, which is operated by the Consolidation Coal Co. as a hygienic measure. The plant has 75 head of Holstein cattle which are regularly tested to ascertain if by any mischance they may have contracted tuberculosis. Milk has been found one of the grievous causes of morbidity among mine workers, and progressive companies following the Ellsworth Coal Co., are installing such dairies as a measure of protection.

IMMERSE AND SPRINKLE COAL TO PREPARE IT FOR MARKET.—At the Manchester and Saragossa strip pits, in Walker County, Alabama, the coal is dumped through a hopper into a washing pan, where it is immersed in water. This soaks off any fireclay that may be adhering to the coal. It is lifted out of this pan by two cast-iron screw conveyors. The coal is then screened and sprayed, thus improving its appearance and quality.

Clean Coal Is Broken Up and Screened Out, Leaving Rock and Bone as Oversize

MANY are of the belief that we are unduly complicating the work of cleaning coal by the use of too many screens, jigs, tables, elevators, settling tanks and dewatering devices. Every week we are hearing of new links in the chain of contrivances and attempts have been made to reduce the long chain by a short-cut method which avoids the use of water and is applicable to certain kinds of mine product where the bone, and of course the slate, is less friable than the coal. One of the most attractive of these simple and dry methods for cleaning bituminous coal is that devised by W. S. Ayres, a consulting mining and mechanical engineer of Hazleton, Pa. It eliminates all fine crushing and the greater part of the screening necessary in other processes.

It is designed to treat that class of bituminous product in which the impurities (bone, slate and rock) are tough and less friable than the coal. This condition is particularly true of many West Virginia coals.

The machine consists of a long cylinder into which the coal is fed, which is so designed, equipped and adjusted that the coal is disintegrated, the impurities remaining practically in the same condition as when fed to the machine. Its capacity as thus far tested is 8½ to 10 tons per hour.

When the slack in the run-of--mine without any treatment is clean enough for making coke, the process is very simple. The run-of-mine is first passed over a 2½-in. or 3-in. mesh screen. The product which passes through the screen is passed direct to the disintegrator. That passing over the 2½-in. or 3-in. mesh is fed to rolls which crush it to 3-in. mesh. This 3-in. product is then passed to the disintegrator. Where there is but little bone in the coal, and consequently but few pieces having fuel value in the refuse from the disintegrator, the tailings can be discarded without re-treating. Where the mine product contains much bone the tailing can be re-treated on the Ayres separator, originally designed for the treatment of anthracite, as shown in the illustration. This bone, or indurated coal, is too high in ash, as a rule, for coke, but it can be used for steam or domestic purposes.

Where the slack in the run-of-mine contains too much ash for use in the manufacture of coke, the disintegrator will reduce the usual equipment of tables and crushing machinery by removing the slate and rock, and by doing the greater part of the crushing before the coal is passed to the machinery for fine grinding.

A test made on a sample lot of West Virginia coal on the disintegrator-separator set, gave the following results: Coal recovered, 98.40 per cent, containing 7.05 per cent ash; coal lost in tailings, 1.60 per cent.

This process, which is covered by basic and combination patents, is entirely dry and is so simple that the machinery installed for its accomplishment occupies but little space, has a comparatively low first cost and can be operated without any attendant other than the oiler.

The separator consists of an apron conveyor set at an angle so steep that the coal which has the least frictional resistance refuses to travel upward with it. The slate having a greater frictional resistance or steeper angle of repose is readily carried upward and discharged at the head of the conveyor. When used in conjunction with the disintegrator only the bone is fed to it which has been more or less rounded by the tumbling in that cylindrical screen. The good bone being more perfectly rounded is disposed to roll to the bottom of the incline, where it can be gathered and used for such purposes as do not need exceptionally clean coal or at places so near the point of operation that the freightage cost of the impurity is not sufficiently great to make the presence of the bone particularly undesirable.

Thus the separator and disintegrator operate on two distinct principles. One depends on the difference in the angle of repose of the pure and impure product and the other on the greater friability of pure coal as contrasted with the strength and cohesion of such associated material as contains a large percentage of ash. Neither is dependent on specific gravity, as are dry and wet tables, jigs, rheolaveurs, Chance separators and similar contrivances, nor on surface tension, as are oil-flotation devices.

Mining Courses by Radio to Be Given by Pennsylvania State College

ENGINEERING extension courses by radio may be established at the Pennsylvania State College, Dean Sackett, of the School of Engineering, said last week. The department already reaches 9,000 industrial employees each year with class and home-study courses.

The Dean announced, "We may find it possible to have the necessary lesson charts and diagrams sent in advance by mail to the radio enrolment, and then the college classrooms can be taken into the shop or home for the benefit of the men who cannot go to college.

It is possible that the day is not far distant when these men and the hundreds of miners in similar classes conducted by the College School of Mines will be able to listen in on scheduled class instruction from the college broadcasting station.

Separator and Disintegrator

The disintegrator on the right breaks the clean coal and screens it out. The separator on the left lifts the slate and silicious pieces and allows the rounded pieces of banded coal—bone to roll to the base of the table, making a second or middlings product for use in steam raising.

Cost of Timber in Illinois Between One And Sixteen Cents per Ton Mined

HARRY E. TUFFT has made an inquiry into the kind and cost of timber used in the mines of Illinois as part of a study to be made by the U. S. Bureau of Mines with the co-operation of the U. S. Forest Service, the purpose being to ascertain ultimately what economies could be effected by better selection, preparation and storage of timber and especially to ascertain how the life of timber may be prolonged by the use of preservatives.

He finds that the cost of timber in the longwall mines of northern Illinois varies greatly from mine to mine. In 1914* the average total cost of timbering in eleven mines was stated as 5 to 8c. per ton of coal produced. The props are usually 3½ to 4 in. in diameter at the small end. The cost of props in 1914 was 0.5 to 1c. per lineal foot. Costs for average sizes of crossbars delivered to the mine were as follows: 6-ft. bar, 8-in. diameter (average), 15c.; 7-ft. bar, 8 in. diameter, 16c.; 10-ft. bar, 10 in. diameter, $1.25; 14-ft. bar, 12 in. thick, $1.90.

The costs of mine timber in 1921 delivered to the mine in this district were stated by one of the large operators as follows: Mine props, 4½ ft. long, 4½ in. small end, 5¾ to 6c.; a 6-ft. prop costs 7½c., a 7-ft. timber, 25c., and an 8-ft. timber, 35c. The average cost for props and mine ties at this company's mines in 1921 was 15.36c. per ton of coal mined.

Cost for Timber Almost Doubled Since 1914

Thus it will be seen that the average cost for longwall props in this district has advanced from 0.75c. per lineal foot in 1914 to 1.25c. per lineal foot in 1921, and that a 7-ft. timber costing 16c. in 1914 now costs 25c. It also will be observed that the maximum cost given in 1914 is 8c. per ton of coal mined, whereas the cost at the mine above mentioned is now 15.36c. for the same unit of output.

The timber used in the coal mines of Illinois is practically all of mixed hardwoods, little soft wood being used. In the room-and-pillar mines both round and split props are commonly used, although some operators prefer round props, as these are said to give better service than those that have been split from a log, especially in the smaller sizes. In the timber specifications of the different companies much variation is found as to the acceptable minimum diameter of props and crossbars. Some companies accept props containing only 4 to 5 sq.in. of wood in the small end, the actual diameter ranging from 2½ to 3 in. Others specify a minimum diameter of 4 in., and a few require a diameter of 5 in. Lengths range from 4½ to 10 ft. and average 6 to 8 ft. Oak receives preference in Illinois.

Most of the operators use practically any kind of hardwood timber for props, but a few endeavor to obtain as large a percentage of oak as possible. Probably more than 65 per cent of the prop timber is mixed oak (red, white, burr, and other), the rest being sycamore, hickory, elm and other varieties.

Crossbars are principally white oak, with some red oak, burr oak, and a little walnut. The diameter at the small end ranges from 4 to 8 in., 6 in. being perhaps the diameter of those most commonly used. The lengths vary from 8 to 20 ft., depending on the width of the opening to be supported. Most operators use only white oak for mine ties, although many accept any kind of hardwood.

Much of the mine timber used in Illinois mines is shipped from outside the state, chiefly from Missouri. In some of the mining districts the local supply of timber obtainable for mine use is limited in quantity and of inferior quality. The cost at the mine varies, according to the length of haul and minimum diameter that the operator will accept, from 16c. for a locally grown 7-ft. prop with 2½-in. tip to 28c. for a Missouri white-oak prop of the same length and measuring 5 in. in diameter at the small end.

The average cost in 1921 for mine props in lengths ranging from 4½ to 9 ft. and measuring 4 to 5 in. in diameter for various mines throughout the Illinois districts is compared in Table I, with the average price for 4½-in. props in one of the Illinois districts, as published in a report issued in 1915 by the University of Illinois.†

From this table it will be observed that the cost of props has increased greatly in the past seven years. Comparative figures for mine ties and crossbars are not available, but individual comparisons indicate a corresponding increase.

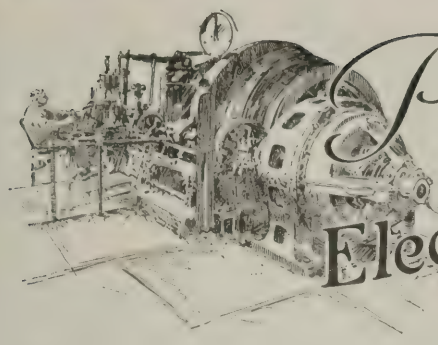
TABLE I - AVERAGE COST OF MINE PROPS IN ILLINOIS (DELIVERED)

Length Ft.	Cents per Prop 1914†	1921	Length, Ft.	Cents per Prop 1914†	1921
4½	4½	8	6½	13	17
5	5	10	7	17	24
5½	6½	12	8	25	30
6	10	15	9	30	35

TABLE II—AVERAGE COST OF TIMBER-SET MATERIAL AND MINE TIES (DELIVERED)

	Length, Ft.	Diameters, Small End, In.	Price in 1921
Round oak post	6	6	$0.45
Oak crossbar	10	6	.75
Oak crossbar	10	8	.85
Oak crossbar	16	6	1.50
Oak crossbar	16	10	2.60
Oak crossbar	20	6	2.00
Mine ties, length, 5 ft. 3x4 in. cross-section			.22
Mine ties, length, 5½ 6x6 in. cross-section			.42

In 1905 the average cost of round timber was 6c. per cubic foot in Illinois. In 1921 the cost of round mine timber delivered to the mine ranged from 17c. per cubic foot upward for a number of representative mines in different districts. From this it is seen that the cost of mine timber in Illinois has increased three-fold since 1905.



In 1921 the cost for prop timber delivered to the mine in twelve mines in southern Illinois was 0.9 to 3.6c. per ton of coal hoisted, and averaged 1.9c. per ton. The cost per ton of coal mined for all mine timber used underground delivered to the pit mouth ranges from 3 to 10½c. for thirty operators producing about 22,000,000 tons annually in different districts, the average being approximately 4.7c. per ton. The consumption per ton of coal mined at these mines ranged from 0.09 to 0.39 cu.ft. per ton, and averaged 0.23 cu.ft.

The report of Mr. Tufft concludes with the statement that one of the ways in which coal-mine operators can reduce their timbering expenses is by treating with a proper preservative the timber to be placed in the more permanent openings.

A GROUP OF FINANCIERS in which the Stinnes interests are prominent is reported to be acquiring participations in upper Silesia iron and coal properties, the first step being the purchase of a large block of shares in the Bismarck works.

Practical Pointers for Electrical and Mechanical Men

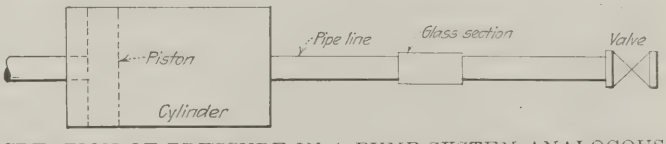
Demand for a Knowledge of Electricity and Its Application to Mining

THE rapid progress and the growing application of electricity to coal mining has brought about a condition which demands that almost everyone working in or about the mines know a little at least about the theory and application of electricity. In fact it is highly desirable that all those in charge of mining operations know a great deal about electricity that they may be able to direct their workers and their personal efforts to better advantage.

With this expansion of electrical application has come an increased demand for more electrical data and information like that which *Coal Age* has been supplying, but there has also come a demand for some more general explanation of the fundamental principles of electricity, such as may readily be understood by the average practical man about the mines. To further increase the service *Coal Age* gives the industry there will appear from time to time short articles explaining the fundamentals of electricity and its application to coal mining.

What is Voltage and Current

The word voltage is one of the most common terms used in electrical literature and it is therefore essential that we have a clear conception of what is meant by the word. Instead of the word voltage the term pressure frequently is used, meaning the same thing.



Voltage means electrical pressure and is quite similar to the idea of pressure as used when considering the pressure of the water in a water line. A pump exerts a certain pressure on the water in the pipe line and this pushing effort exerted, say by the plunger of the pump, is transmitted to the water.

Let us suppose we have a cylinder and piston filled with water and connected to a pipe line, with a valve on the end of the pipe as shown in the accompanying figure. If the piston is pushed from left to right there will be created and transmitted to the water a pressure. Should the valve be closed the pressure would still be exerted upon the water but there would be no flow of water; should the valve be opened the pressure would still exist but it would be in use and moving the water in the pipe line. Note that the pressure exists whether or not the water is still or in motion.

Electrical pressure, or voltage, is quite similar to the above. Voltage is electrical pressure which is created and may exist in a conductor or wire ready to cause a current to flow or it may be causing a current to flow. We should note that voltage, like pressure on the water, may exist either when not causing an actual flow or when causing a flow.

If the pressure exerted on the piston is allowed to push the water, the valve being opened, we say that there is a flow of water in the pipe line, similarly, if certain conditions are brought about where we have a voltage, or electrical pressure, on a wire a flow will be created called a current.

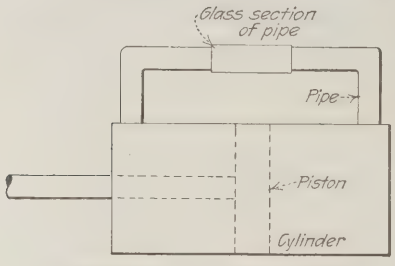
In our water analogy with the pump, the flow may be measured in gallons per minute. It is not necessary to determine the rate of flow by measuring the water coming out of the valve at the end of the line because a meter may be inserted anywhere in the pipe line and used to measure the rate of flow. We may even put a glass section of pipe in the line and actually see the water passing through the pipe line. When we see the glass tube full of water we say the rate of flow of water is high and obviously when the tube is not so full we say that the rate of flow is low.

CREATION OF PRESSURE IN A PUMP SYSTEM ANALOGOUS TO CREATION OF VOLTAGE

If the valve in the illustration is closed and the piston is forced from left to right, the water in the pipe will be under pressure although the water is not flowing out of the pipe. If the valve is opened the pressure will be used in forcing water through the pipe. This is similar in the first instance to voltage on an electrical system without current flowing; while in the second instance the electrical pressure or voltage would be producing a flow of current, the rate of which may be measured in amperes.

In measuring the rate of flow of water in a pipe line we usually say that the rate is a certain number of gallons per minute.

When an electrical pressure is used to cause a flow we say a current is flowing, similar to water; but in measuring the rate of flow in the wire we usually use the unit called the ampere. Therefore, the rate of flow of the current in an electrical conductor is expressed as a certain number of amperes.



The Difference Between Alternating And Direct Current

THERE are two important different kinds of voltages used around the coal mines, one called direct-current voltage and the other called alternating current voltage. These two terms actually mean that the first named kind of voltage will cause to flow a direct current while the other kind will cause to flow an alternating current.

By direct current we mean current which whenever it is flowing will flow continuously in the same direction in a given wire. This is again similar to a pump line. Whenever a pump is operated, the flow through the column line always is in a direction away from the

pump. With electricity, whenever current flows in the same direction in the wire we are considering, we call it direct current.

In a pumping system the flow of water in the column line always is up or unidirectional, due to the arrangement of the valves, regardless of the direction in which the piston or plunger in the pump may be moved. Such a unidirectional flow is similar to what is termed direct current in electrical language. Moving the piston to and fro in the cylinder shown at left will produce a flow of water which will alternately be moved first in one direction and then in the other, that is, if we look at the water flowing through the glass section of the pipe the flow of water will be alternating from one direction to the other as the piston is moved backward and forward. Such an alternating flow is called alternating current, in electrical language. Note that the motion of the piston creates an alternating pressure and it is necessary to have this alternating pressure to produce an alternating flow of water in the pipe section. Similarly, an alternating voltage is necessary to produce an alternating current.

ILLUSTRATING ALTERNATING CURRENT

Working the piston forward in the cylinder would force the water that was in front of the piston up through the pipe connection and back into the cylinder behind the piston; reversing the stroke would cause the circulation of water to reverse in direction. If the piston were operated to and fro continually, the alternations of the direction of the water through the pipe would give a good example of the flow of alternating current in an electrical conductor. One hundred and twenty such alternations of flow are made each second in a 60-cycle alternating current system.

The Open Delta Connection

WHERE continuity of service is of great importance to an operation it is frequently common practice to install a bank of transformers of excess capacity and connect them in delta. When one transformer burns out or becomes disabled the service may still be maintained by operating the remaining transformers in what is known as "open delta."

The "open-delta" connection is similar to the "delta" connection, previously explained, except that one transformer is left out. This connection is also sometimes called the "V" connection because the delta connection and diagram represents a V when one transformer is omitted.

An important point in considering the "V" connection is that there will be available for load under this connection only 87 per cent of the capacity rating of the transformers, or in case the connection was originally delta the remaining capacity of the bank after one transformer has been eliminated is only 58 per cent of the original capacity. For example, assume each transformer of a delta bank to have a capacity of 50 kva.; the bank will then deliver 150 kva. When two of these same transformers are operating in "open delta" the capacity will be 50 $\times$ 2 $\times$ 87 per cent = 87 kva., the "V" connection capacity; 87 kva. $\div$ 150 = 58 per cent of original capacity.

In localities where repairs cannot be made hurriedly and where the breakdown of a transformer would result in serious consequences this scheme is used. However, to keep down the no-load losses of the transformers where overcapacity is arranged for the extra transformer is left disconnected and the bank operates normally on "open delta." Some means, however, should be made for keeping the spare transformer in good condition and always ready for service. An important factor in this connection is the prevention of moisture getting into the transformer and oil.

Data for Artificial Load by Means of A Liquid Rheostat for Testing

IN RUNNING load tests on new or repaired electrical equipment it is sometimes impossible to use the normal operating load for this purpose because of inability to regulate and control the load properly. In this case recourse must be made to some form of artificial load which can be easily controlled and regulated to suit the requirements of the test. For this purpose there are several methods, some of which are highly efficient and others which dissipate the energy in heat.

In the first class are feed back systems. In this system the machine to be tested usually is operated as a motor and is connected to a generator which is driven by the motor under test; the generator in turn is connected so that it feeds back in the system that drives the motor and thus the power cost of the test is represented by the losses in the two machines.

A more common form of artificial load is the liquid rheostat made up of an electrolyte of either an acid or a salt. The acid electrolyte is frequently a solution of sulphuric acid and the salt electrolyte is commonly made from ordinary table or rock salt and water.

The resistance of ordinary hydrant water per square foot cross section and foot in length is approximately 100 ohms. This is a very high resistance and it is therefore necessary to make an acid or salt solution to reduce it to within a practical range for the test.

The following information will be found useful in making up a solution for a liquid rheostat.

When diluted with commercial sulphuric acid the resistance will be as follows:

Per Cent Acid by Weight	Resistance in Ohms
0.174	4.12
0.435	1.75
0.724	1.10
0.985	0.85

When diluted with commercial table salt the resistance will be as follows:

Per Cent Salt by Weight	Resistance in Ohms
0.23	7.84
0.46	4.65
0.70	3.12
0.93	2.38
1.16	1.90
1.39	1.48

In the barrel-type rheostat where the solution is not agitated and cooled there should be from 600 to 1,000 cu.in. of solution per kilowatt absorbed. The plates of the electrodes should have an area of 1 sq. in. per ampere.

Problem of Electric Power Supply for the Coal Mine*

Difficulties in the Way of Adapting Old Plants to New Equipment—Important Economic Considerations in Planning Extensions—Apparent Power Costs and True Power Costs

By A. L. Jones
District Engineer, General Electric Co., Denver, Col.

THE accepted form of power for the coal mines is electric power, and experience has shown us that we are still far distant from the day when further electrification will not be necessary. The executive of a mine which makes its own power is therefore wrestling almost continuously with the problems of his power plant. Either it is overloaded and must be enlarged and rebuilt or its operating costs are excessive, or it breaks down and limits coal output, or someone wants to sell new and improved machinery, until the manager almost hates the thought of such a restless part of his property. If he purchases power, every day a new use for it seems to be found.

In many ways this unrest is due to short-sighted policy toward the problem, and the tendency when the problem of extension has to be met to dispose of it in the cheapest way and without thought as to where the future is leading.

The day when each opening had its own boiler plant, steam hoist, steam driven fans, steam pumps, steam loaders, etc., seems to be far behind us. During the last fifteen years nearly every mine power house has doubled or trebled in capacity, or has been abandoned in favor of purchased power, resulting in greatly reduced labor and fuel costs. Power costs in such isolated plants which were once considered normal would be unthinkable today, in fact probably would cause bankruptcy.

Purchased Power Decreases Cost Per Ton

One property where the main power supply was by compressed air from steam-driven compressors, used under its boilers 8.35 per cent of all the coal mined. The cost of power was 12½c. per ton. Another property having four openings, each with its own boiler plant and usual equipment of steam hoists, pumps, etc., had a power cost of 10.3c. for each ton mined; and these were in the days when the present high prices for coal were not obtainable. Another property operating two mines mostly by steam used 11.1 per cent of the coal output under its own boilers and the power cost was 19.45c. for each ton mined. Each of these properties is now electrified and power costs are from 3 to 4c. per ton mined, and the fuel burned runs from 1 to 2 per cent of the output.

With the broadening market and high prices for slack coal and the high cost of labor in boiler and engine rooms, the cost of steam is reaching a high figure, and efforts must be made to keep this down by a more efficient steam production and by utilizing this steam in improved machinery that will increase the work done by each pound of coal burned. It must not be overlooked either that the plant that is very wasteful of fuel usually is an old one and probably far from being reliable. In a general way the more efficient the plant, the greater its reliability.

Ample and reliable power supply means ability to get out coal when there is a market. The increasing use of purchased power is largely due to changing conditions which are tending constantly to push up the cost of power, unless the most efficient machinery is used and large-scale production is possible. Better load factor and more efficient equipment permit the central station to sell power to mines cheaper than a small plant can produce it—if all the factors of fixed charges are given proper weight.

Frequent Additions to Plant are Costly

Few coal properties start with a full-grown plan of development or with sufficient capital to permit the installation of a power plant much ahead of their immediate requirements and each addition to the plant is only to care for some immediate and pressing requirement. A mine executive might think that this condition of having his power plant always in a state of change is a peculiar condition of his property or his industry, but such is not the case. The public-utility company with power generation its main business recognizes this condition and plans ahead as far as its finances will permit, thus eliminating many of the expensive changes which must be made to a growing mine power plant.

The most important factors in planning any changes in a power house are foresight and confidence that the power plant will subsequently be called upon for a greater output, and it is here that the central-station public utility has a marked advantage.

Assuming an existing power plant consisting of a number of non-condensing steam engines which are proving inadequate for the requirements, what is the best way to enlarge? Before the decision to increase the plant has been reached the margin of safety in spare units probably has been getting smaller and smaller, until during the day shift everything has to be operated. To take full advantage of progress in generating equipment and higher efficiency the new unit should be as big as the combined capacity of the installed engines and enough bigger to provide for the immediate future, the idea being to operate the new unit during the day shift and hold all old units as spares. The new unit naturally would be more economical in its use of steam and if 7,500 kw. or larger, serious consideration would be given to the question of condensing operation, which would use approximately half as much steam as with non-condensing operation, even if this involved the use of a spray pond or cooling tower.

It should also be recognized that the tendency is toward higher steam pressure and superheat and those factors should be incorporated in the new installation.

*Abstract of paper read before Rocky Mountain Coal Mining Institute.

The new equipment should be so located in the power house that the next move, which logically would be to supersede the old engines with still another turbine, would involve no conflicts and the units be so placed that the ultimate goal would be a well laid out power house with ample room both on the turbine floor and around the condensers.

The switchboard for the new turbine should be laid out not to match the old board but with an eye to the future, incorporating modern practice and having ample capacity in oil circuit breakers. The march of progress will wipe out the old board and the standard for the new panels should be raised to that of the future, not lowered to that of the past.

The spray pond would be laid out so that it could be extended as the plant grows, and runs of piping, headers, etc., all laid out to permit making additions in the future with minimum interruption to service. In other words in adding a turbine to the plant one should have in his mind's eye the exact location of still another unit and should make all arrangements accordingly. The practice of placing machinery in any hole that presents itself, without regard to symmetry or correlation with other apparatus, or with no ultimate plan in view, is criminal. Nothing tends to raise the morale of the power-plant operating force more than a well laid out and convenient power house, and high morale means better service, lower costs and high output.

Water Supply an Important Problem

A good supply of condensing water from some stream is the most important consideration in determining the location of the plant and might in many cases justify the location of the power plant miles away from the tipple, involving as this does handling of coal. A spray cooling pond at best is a mighty poor substitute for a running stream. Unfortunately, few coal mines are situated near flowing water and must resort to artificial cooling of the condensing water, so the plant can be located where it will best receive coal and otherwise serve the load. Provision for future growth may show that the existing power plant building is incapable of being extended, in which case the fact must be squarely faced and the first turbine installed on a site and in a building which will permit of the ultimate expansion.

Probably the boilers which supply the original generating equipment are small units, of low-pressure type, in which event it must be remembered from the start that when the plant reaches any considerable size such boilers will have to be superseded by larger units perhaps of different design. The logical working out of the problem would be to install one boiler large enough to supply the first turbine installed, holding the other boilers as spares. This new boiler would be set high and would be so placed that coal- and ash-handling machinery could be provided at a later date with minimum disturbance to service. This boiler, too, would be purchased with the idea that ultimately it would have to operate at much higher pressures. Such a boiler would be twice as high as the old units, and its height, alignment and position should be selected for the future, regardless of how it fits into the present situation. Unfortunately, in most stations tying on to the present layout seems to be the determining factor, regardless of the handicap under which the new equipment may be placed.

The design of a mine power house involves innumerable details, such as selection of jet or surface condensers, type of stoker best suited to the coal to be burned, method of treating feed water, etc. The executive should keep his mind sensitive to the fact that he is not installing one unit only, but is making a start and preparing the ground for future extensions.

The mine power plant operates under a great many handicaps; usually water is scarce and poor, good boiler water frequently having to be hauled or pumped long distances. Poor water in boilers means extremely heavy maintenance, shorter time between cleaning, inability to overload, etc. Cooling water for condensers usually has to be circulated through towers or spray ponds and recooled. While such a cooling device may be used it is at the expense of lower vacuum, scale, high pumping cost and extra cost of equipment.

Mine plants seldom can afford specially trained supervision and the labor obtainable frequently is not the best and is fixed at a high price.

The very existence of a mine plant seems to foster the idea throughout the property that power costs little or nothing and that there is no particular need to conserve it. One property presented a most glaring case of wasted power. This company's problem was to raise a relatively small quantity of water from the mine. A centrifugal pump of many stages was on hand which had been used on much higher head, but rather than get a new pump the runner was turned down so that the motor would not be overloaded, some cable was already installed which was too small, but it was used at the expense of a heavy voltage drop. The steam was made in inadequate boilers and the engines in the power house were practically junk. They drove a jack shaft, which in turn drove back to a generator.

Glaring Waste of Mine-Made Power

Investigation of the efficiency of this pumping showed the situation to be as follows: The engine took 410 b.hp. in steam, 108 hp. was lost between the engine and the terminals of the generator; 65 hp. was lost in the cable, 23½ hp. in the motor, 187 hp. in the pump and 26½ hydraulic hp. of useful work was done—410 hp. in steam to do 26½ hp. of work. This had gone on for years and had caused no comment, because power was thought to be cheap. This is the mine which used 11.1 per cent of its coal output under the boilers. Fortunately, cases as extreme as this are not common. Cheap power is not found around coal mines.

The generation of power is as specialized and distinct a business as that of mining coal, and industry in general is overwhelmingly abandoning its isolated plants and turning to purchased power. In many of the larger coal fields custom power is available and a considerable proportion of coal in such fields is mined by purchased power.

The cost of such power seems high to the mine manager, who may think of his power cost as made up of some slack coal and small payroll, whereas the power company knows all too well that dozens of other factors must be reckoned with, which over a term of years cost real money.

Power may or may not be available to all mining properties, and if it is available the wise executive will look at the long-range and over-all cost of this power, and if he does this he will have more sympathy with the rates charged for custom power.

Any haphazard program of power-plant expansion

costs money and the money stays in the plant, causing the accumulative cost to run into startling figures. All the early equipment is soon practically obsolete, and if not actually thrown out it is worth little more than scrap. The practice of charging 5 to 6 per cent per year for amortization on investment is far too low for a mining property, especially one which develops gradually and where the power plant has to keep pace with an expanding and changing property. Very little equipment for power-house use purchased twenty years ago can compare favorably in efficiency with modern equipment; some of it fell by the wayside in much shorter time than this. It would seem that charging 7 to 8 per cent yearly for the obsolescence of the machinery is not too much.

The public-utility man has the same problem, but with his diversified load and his confidence in future growth he is in a better position to look further ahead, installing larger units, so that his charges on this score, while heavy, are less by a considerable margin than those of the mine plant.

The rate of interest which must be paid on power-plant investment varies from time to time with the money market and the cost of raising this money. The public-utility company with its larger units and better load factor probably has less invested per kilowatt capacity than the mine plant, especially as the spare capacity is available for diversified load, whereas the mine plant naturally requires a larger proportion of idle capacity. Some authorities maintain that it is justifiable to charge against the power plant the profit which money invested in the power plant would have earned if invested in the coal-mining business. This is based on the assumption that there is a limit beyond which the business cannot economically borrow money or beyond which it is not advisable to do so. Few companies would consider an estimated profit of 5 per cent above the interest charges sufficient to undertake the hazard of the business. This may or may not be considered a valid argument. Taxes fall alike on the public utility and on the mine plant. Fixed charges against the mine plant might be taken somewhat as follows: Interest, 7 per cent, taxes and insurance, 2 per cent; amortization, 8 per cent, making a total of 17 per cent.

High Capital Investment in Mine Plant

The amount invested per kilowatt of capacity in the usual mine plant in relatively small units is bound to be high. Almost any mine plant will show an investment of about $150 per kilowatt including boiler plant, building, etc. Then too, this investment is not used to full capacity all the time. In fact few mine plants have as good a load factor as 50 per cent, 33⅓ per cent being nearer the average, and the annual load factor, taking into account idle days, usually is not better than 25 per cent. Load factor in this sense is defined as actual kilowatts produced per month, divided by 720 hours per month, multiplied by maximum 5-minute peak encountered—in other words, the ratio of the actual power produced to that which would have been produced had the plant operated every hour of the month at a rate equivalent to the 5-minute peak encountered.* Over the month or year this represents the use of only 25 per cent of the possibilities of the plant, but the fixed charges, labor charges, etc., are chargeable on the basis of 100 per cent operation.

Taking the fixed charges at 17 per cent and assuming $150 invested in the power plant for each kilowatt output, the fixed charges become

$$\frac{17 \text{ per cent}}{8{,}760 \text{ hours per year}} \times \$150 =$$

0.29c. per kilowatt produced. On the basis of 100 per cent load factor, with actually a 25 per cent annual load factor the charges become 1.16c. for each kilowatt turned out. Investigation of quite a number of situations will show that the fixed charges of a mine power plant will run about 1c. for each kilowatt produced. This must be added to the actual production cost for the true cost of the power. Generation costs in mine plants vary greatly due to the load factor, degree of efficiency, modernity of equipment, character of supervision, etc.

A good size plant having condensing turbines but difficult water conditions had an actual generating cost of 1.37c. per kilowatt-hour. The cost was distributed as follows: Coal, 29½ per cent; labor in boiler and turbine room, 26½ per cent; boiler and stoker maintenance and boiler changing, 24 per cent; water, 20 per cent. Another plant, somewhat larger, and with better water conditions, had a cost of 1.277c., divided as follows: Coal, 52.2 per cent; labor in boiler and turbine room, 27 per cent; boiler and stoker maintenance, 10.8 per cent; water, 10 per cent.

The above were 1916 costs; probably on the basis of today's coal and labor prices they would be double, or 2.74c. and 2.55c. respectively. To these costs should be added about 1c. for fixed charges, bringing the cost to 3.74c. and 3.55c. Modernizing and combining these two plants cut the cost considerably. From these facts we may venture to say that few coal-mining plants can produce power at less than 2c. per kilowatt including fixed charges.

The argument then is that power is not cheaply produced around a coal mine, that purchased power will in many places be a wiser plan than revamping an existing plant or continuing to use an obsolete one. The power companies penalize for poor load factor, but so does the mine power plant, both in operating economy and in fixed charges.

*Basing the load factor on a 5-minute maximum demand is hardly a fair basis, because it would be impractical to operate mine power-plant generating equipment continuously for 720 hours at the 5-minute maximum demand rate. However, intimate contact with thirty coal-mine operations shows that the yearly load-factor is approximately 25 per cent when based on the capacity of the generating equipment.—Editor.

Fill Prospect Drillholes with Concrete

By Carl Scholz
Vice-President and General Manager, Raleigh-Wyoming Coal Co., Charleston, W. Va.

DRILLHOLES put down for prospecting purposes should be filled with concrete as soon as completed to a height of, say, 50 or 60 ft. above the coal. This is of special importance where water occurs in the overlying strata. In developing the Glen Rogers mine a heavy influx of water occurred 450 ft. above the coal, and it readily will be seen that if a roadway were driven under such a borehole without its having been concreted, much material damage might be done.

When the hole is first made its walls are intact and no sediment has filled up the bore, but if the work of concreting is left till later it may not be easy to make so good a job. A borehole is of no further value after the core has been obtained, so nothing is gained by leaving the hole to fill with sediment and to cave, for such a policy will inevitably give trouble.

Problems of Operating Men

Edited by James T. Beard

What Happened to a Pile of Creosoted Timber

Story of an Eye Witness—Pile of Creosoted Mine Timber Fired by Spark from Locomotive—Water Failed to Extinguish Fire

HAVING been a reader of *Coal Age* since its first issue came off the press, more than a decade ago, I feel assured that its editor would not knowingly publish anything if the information conveyed would prove harmful or dangerous to life and property, in mining. It was this thought that has induced me to give the following brief account of an occurrence of which I was an eye witness. The story is in no way exaggerated and I can vouch for its truthfulness.

The incident is recalled to my mind by reading the editorial, "Is Creosoted Timber a Menace?" which appeared in *Coal Age*, Feb. 15, p. 284. The information given in that article tends to show that the creosote treatment of timber does not increase its inflammability. This conclusion is based on the report of a committee appointed by the Missouri, Kansas and Texas R.R. to study the effect of creosoting fence posts, in respect to its effect on their destructibility by fire.

Without questioning the report and conclusions of this committee, as given in the editorial, kindly permit me to recount what I saw take place when a pile of creosoted timber, which had just been delivered at our mine, was fired by a spark from a small locomotive operating on a track in the timber yard.

Story of an Eye Witness

At that time (1910), I was running a mine hoist, at one of the large shaft mines here in Nanticoke. The company had a creosoting plant at one of their other mines and had sent over two flat cars loaded with mine timber that had been treated with creosote. This had been unloaded just outside of the enginehouse door, only that morning.

When I came out in the evening, ready for the night-shift, I observed the small locomotive coming up the track. Just then a signal for lowering men called me to the throttle. The shaft was 700 ft. deep and a single trip of the cage required a minute and a quarter when hoisting and lowering men.

Returning to the doorway, a few moments later, what was my surprise to behold a volume of smoke coming from the pile of timber. Evidently, the fire had caught from a spark or hot coal falling from the engine. Without seeing it, one would hardly believe the volume of dense smoke that was given off from the burning pile. It resembled the discharge from two big locomotives pulling a heavy trip of cars up a mountain grade.

The alarm was quickly given, but water appeared to have no effect to extinguish the fire, which continued to smolder and burn until it had consumed the entire pile. I could not help but think what would have been the result had this timber been sent into the mine and the fire had taken place on the mine road.

The following morning, the mine superintendent was early on hand to view the place. I remarked to him that had the timber been ignited in the mine, not a man or animal inside of the burning section would have been able to escape through the dense volumes of smoke produced by the burning timber. He agreed with me and put himself on record then and there against the use of creosoted timber in the mine.

In closing, allow me to suggest that the use of the cement gun and the coating of mine timbers with "gunite" is of far greater practical value as a preservative of timber and is not a menace to the safety of the mine. I hope this brief account may be of some value in averting disaster.

Practical Working of Mining Law Requiring Exclusive Use of Locked Safety Lamps

Disputed authority of district inspector referred to Chief of Department of Mines, who appoints other inspectors as committee to investigate and report. Failure to agree then requires submission to Court.

SOME time ago the question was asked in *Coal Age:* "In what respect can our mining laws be improved?" The question did not meet the cordial response that one could hope it would evoke among mining men who read *Coal Age* every week. To my mind the subject is a matter of the gravest importance and should call for earnest thought.

Mining laws should not be like an old fiddle that can be made to play any tune at the will of the operator or mine owner. By way of illustration, let us assume that John Doe and Richard Roe are joint owners of a mine, which they have been operating in the past as an open-light mine.

Somewhat later in the development of the mine the district mine inspector, following one of his visits to the mine, reaches the conclusion that the safe operation of the place depends on the exclusive use of locked safety lamps. Naturally his decision does not meet with favor on the part of the owners, who defy his authority in the matter.

As required by the Bituminous Mine Law of Pennsylvania (Art. 10, sec. 1), the district inspector reports the matter to the Chief of the Department of Mines, and two or three other inspectors are appointed to investigate and report their finding within seven days after their appointment.

In the event that the mine owners still refuse to accept the conclusions of the committee of inspectors, the law allows another seven days in which the owners

are given the right to appeal to the Court of Quarter Sessions of the county. The Court must then appoint five practical, reputable and competent persons, two of whom shall be selected by the owners and two others by the Chief of the Department of Mines and a fifth chosen by the four already named, or by the Court after waiting five days.

A third seven days are allowed, by law, for the formation of this commission, who must examine said mine and report their findings to the Court within ten days. Even then the law provides for the filing of exceptions by the owners or by the Department of Mines within seven days more.

Here, let me ask, What may happen in the mine where dangerous conditions are alleged, and who would be responsible in the event of disaster? Does not the law make the mining staff look like a set of school boys? What does *Coal Age* and its readers think?

Parnassus, Pa. C. W. ATKINS.

Circulation in Safety Lamps

Heating of the gas-charged air within the lamp reduces the pressure in the combustion chamber and increases the velocity of the air entering the lamp.

PERMIT me to correct a misstatement made in the letter of Oscar H. Jones, *Coal Age*, March 22, p. 493, in which he criticizes my theory of the lengthening of the flame of a safety lamp exposed to a firedamp mixture. The misstatement to which I refer grows out of a misconception of the illustration I used to demonstrate my theory.

While seeming to have a clear conception of the theory of the effect of the heating of the air entering a safety lamp, my critic's idea of the conditions on which this theory is based is wrong, and it is this error that I wish to correct. The misconception lies in the difference between the effect of the heating of pure air and air that is charged with gas.

For the same volume of flame, or a given combustion surface, the heating of pure air produces a normal height of flame, in a safety lamp or any other lamp. The lighter methane mixture (firedamp), subjected to the same heating, of course, follows the same natural law. Consequently, there is a reduced pressure within the lamp when the air entering is charged with gas, as compared with the effect of the heating of normal air.

Velocity Increased by Reduced Pressure

Now, it is not my idea that this reduced pressure, in the vicinity of the flame, increases the upward pressure of the air entering the lamp as a fuel supply, as my friend's statement seems to imply; but that the reduced pressure within the lamp increases the velocity of the air entering the lamp when that air is charged with gas. I believe this is strictly in accordance with natural law, the greater the difference of pressure, the more rapid the flow of air resulting.

Exception was taken to my comparing a safety lamp with an ordinary house lamp. While the two lamps are different in construction and use, the principle of ventilation is precisely the same in each, and I used the illustration to demonstrate the fact that the same cause would produce the same effect on the flame, in each lamp, notwithstanding their different construction.

However, the following illustration will serve the same purpose and perhaps be more acceptable. For example, take a safety lamp, burning with an ordinary height of flame in the mine, and carry it into an underground office or shanty where the confined air is at a somewhat higher temperature. Set it on the table and allow it to remain there for a short time.

Heated Atmosphere Causes Lamp to Smoke

Observe the effect produced on the lamp flame now burning in the close heated atmosphere. The flame will soon expand to fill the lamp, soot the gauze and glass and, eventually, will be extinguished by reason of the obstruction of the circulation within the lamp chimney, owing to the deposition of carbon in the chimney, which blocks the discharge of air and gas from the lamp.

Let me ask, What is the cause of the elongation of the flame, in the instance just given, assuming there is a total absence of gas in the air entering the lamp? Is it the "reaching up" of the flame for oxygen, or the forcing up of the flame by the increased velocity of the air supply?

Let me suggest, in closing, if Mr. Jones will try the experiment with the house lamp, which I mentioned in my previous letter and which he objects, he will discover that the flame will become elongated before being extinguished, which was the fact I wished to illustrate.

Washington, D. C. I. C. PARFITT.

ANOTHER LETTER

Practical test shows entry of air through the gauze, as well as through the openings below the flame, in lamps designed on the Eloin principle.

REGARDING the question of whether air ever enters through the gauze chimney, in lamps provided with openings below the flame, permit me to say that the simplest method of deciding this question is to put the lamp to the practical test and observe the results. Nothing is more simple than to show by experiment the flow of the air current entering a lamp and the escape of the products of combustion.

For that purpose, allow me to suggest making this experiment on the surface, and choosing for that purpose any approved safety lamp provided with openings below the glass to admit the air to the combustion chamber. When this experiment is performed in a room on the surface, in broad daylight, and the flame of the lamp adjusted to a height suitable for safe working or for testing for gas, there is no difficulty in observing the circulation of the air currents within the lamp.

In making the test, the lamp should be arranged so that smoke will surround the top of the chimney. When this is done it will be observed that the smoke will enter through the gauze and much of it descend to the flame, while air enters through the lower opening.

Smoke Shows Course of Circulation

In order to observe the discharge of the products of combustion, make another test in which the flame is raised to such a height that it smokes. The course of the ascending current is then shown by the smoke rising until it is discharged at the top of the lamp. Of course, when the test is made in the mine the gas-charged air burning in the lamp raises the temperature and greatly increases the volume of the products of combustion given off from the lamp.

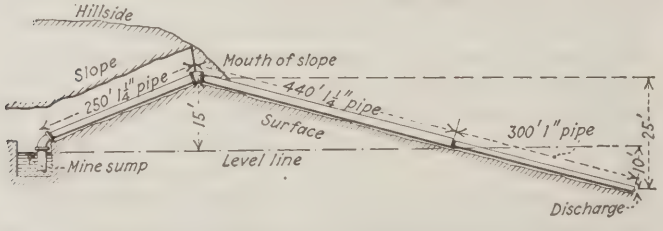
In closing, I may state that, in 1912, two mine ex-

plosions occurred in this country that were attributed to modern double-gauze lamps burning naphtha. In one of these explosions, twelve lives were lost. It was stated that the lamp that failed was not properly assembled, the gasket over the glass cylinder having been found to be doubled, causing the lamp to leak at that point.

A second accident in which several men were burned was said to have resulted from the puller rod, which operates the striker when igniting the lamp, having been left out. I mention these incidents as showing that in each of these cases the firedamp mixture entered at the bottom of the lamp. FRANK PATTERSON.

Eldorado, Ill.

Inquiries Of General Interest



Siphon Problem in Mine Drainage

Flow of Water from Supply Basin Summit Must Equal Flow in Entire Length of Pipe Line, to Insure Continuous Operation of the Siphon

HAVING been an interested reader of *Coal Age*, for several years, and a student of the many practical problems answered in its columns, I take the liberty of asking the solution of a proposition regarding the siphoning of water in a mine. It is as follows:

We are operating a small coal mine that has been opened on a slope. The slope is 250 ft. long and falls, in that distance, 15 or 18 ft. At the foot of the slope we have arranged a sump to catch the water coming from the mine. We attempted to siphon this water out of the mine by laying a 1¼-in. pipe line up the slope and extending it down the hillside, on the surface, to a point considerably below the level of the water in the basin, in the mine.

As shown in the sketch I am sending, there are 250 ft. of 1¼-in. pipe, in the slope, in the mine, and 440 ft.

SHOWING PROFILE OF SIPHON PIPE LINE

of the same size pipe continued on the surface. Then follows 300 ft. of 1-in. pipe, making the entire length of the pipe line 990 ft.

The result is not satisfactory, as the flow through the pipe line is not sufficient to drain the sump, which overflows at times and then baling must be done and the water hauled out of the mine in a water car. The question I want to ask is, Should the smaller 1-in. pipe have been used on the suction end, instead of at the discharge end? Would making this change increase the flow of water in the siphon? D. L. REITZ.

Cairnbrook, Pa.

When using two sizes of pipe, in siphoning, the smaller pipe should always be laid at the discharge end, as in this case. The flow of water in the siphon would not be increased but rather decreased by making the change suggested by this correspondent.

We have made a few calculations to ascertain the probable flow in the pipe line, under the conditions shown in the accompanying figure, which represents the sketch offered by the correspondent, except that we have assumed the total fall, from the crown or summit of the siphon, at the mine entrance, to the point of discharge on the surface as, say 25 ft. Also, as indicated in the figure, we have taken the rise from the water level in the sump in the mine to the crown or summit as 15 ft. This makes the total assumed effective head producing the flow of water in the entire line of pipe 25 — 15 = 10 ft. Then, calling the respective diameters of the two sizes of pipe d_1 and d_2, the respective lengths l_1 and l_2, the effective head, in feet, H, and the flow of water, in gallons per minute, G, the flow of water in the pipe line is given by the formula,

$$G = \sqrt{\frac{800\,H\,(d_1 d_2)^5}{l_1 d_2^5 + l_2 d_1^5}}$$

Then, substituting the given values in this formula, we have for the required flow of water in the pipe, under the assumed conditions,

$$G = \sqrt{\frac{800 \times 10(1 \times 1\tfrac{1}{4})^5}{690 \times 1^5 + 300(1\tfrac{1}{4})^5}} = 3.9 \textit{ gal. per min.}$$

It is never safe to stop here and not ascertain whether the flow of water under the atmospheric head (34 ft., sea level), in the suction pipe, will be equal to or greater than the estimated flow for the entire pipe line, under the effective head (10 ft.). If the flow in the suction end should be less than the estimated flow in the pipe line, the siphon will tend to empty itself in a short time.

The rise on the suction end, in this case, being 15 ft., the effective head producing the flow of water in the suction end, under atmospheric pressure, is 34 — 15 = 19 ft. The length of the suction pipe being 250 ft. and its diameter 1¼ in., the flow of water from the sump to the crown or summit of the siphon is given by the formula,

$$G = \sqrt{\frac{800(34 - h)d^5}{l}} = \sqrt{\frac{800 \times 19(1\tfrac{1}{4})^5}{250}}$$

$$= 13.6 \textit{ gal per min.}$$

This shows that the flow in this pipe line will be continuous, since the flow in the suction end is greater than that in the discharge end of the pipe. These calculations are based on a total fall of 25 ft. from the summit to the discharge end of the pipe. The flow in the pipe line would be much increased by using 1¼-in. pipe throughout, as the small 1-in. pipe, at the discharge end, obstructs the flow. In that case, it might be necessary, however, to use 1½-in. pipe on the suction end, in order to prevent the siphon from emptying itself under the assumed conditions.

[A correspondent whose name is not attached to his letter, writing from Duquoin, Ill., asks: "If it is 8 ft. to the coal, which is 7 ft. thick and so situated that water will drain to the first opening, what kind of a siphon would be most practical to drain the mine?"

This is only a sample of many communications that come to *Coal Age*, in the expectation that an answer will be given, when the necessary data are lacking and there is nothing to show from whom the communication comes.

Another correspondent writing from Hawk Run, Pa., asks for "A little information on how to find the revolution of a fan that produced 30,000 cu.ft. of air. What is the horsepower, also the water gage?" We amplified this question to give an intelligent reply and explained (*Coal Age*, April 5, p. 570) that the speed of a fan, for a given air volume, depends on the water gage against which the fan must operate, as the same fan, running the the same speed will produce different quantities of air at different mines having different resisting powers (potentials).—EDITOR.]

Examination Questions Answered

Mine Managers' Examination, Springfield, Ill., Mar. 19, 1923

(Selected Questions)

QUESTION—*What precautions should be taken in blasting, to safeguard employees in mines that are dry and dusty and generate explosive gas?*

ANSWER—Only permissible explosives should be used in such mines. Where the miners are permitted to charge and fire their own shots, all holes should be examined by a competent person, and no hole should be charged or fired until it has been so examined and permission granted. Before the firing of a shot, the place should be examined for gas, such examination to be made by the mine examiner (fireboss), using an approved type of safety lamp for the purpose. In many cases, it will be safer to employ shotfirers to charge and fire all holes drilled by the miners and deemed safe in the judgment of the shotfirer. This work should be done after the men have left the mine for the day.

QUESTION—*In what season of the year and why are dangers from coal dust to be expected, and to what extent would you allow coal dust to accumulate or to be deposited before considering it dangerous?*

ANSWER—The danger from coal dust is greater in the winter season, for two reasons. First, the air current enters the mine at a temperature generally below that of the mine workings. In passing through the mine its temperature is raised and its capacity for absorbing moisture greatly increased. The moisture thus absorbed by the air current renders the mine dry and dusty and this action is greater in the winter than in the summer season. Second, owing to the increased demand for coal in the winter time, mine activities are increased and larger quantities of dust are produced in the mine workings.

No undue accumulations of dust should be permitted and every practicable effort should be made to prevent the deposition of dust on the timbers and walls in the mine passages and working places. Such accumulations of dust as cannot be avoided should be considered dangerous when the air current carries an appreciable amount of fine dust in suspension.

QUESTION—*What changes are met with in coal, roof and bottom when approaching faults and what dangers may be expected therefrom?*

ANSWER—In driving openings in proximity to faults, a good roof will often become dangerous from the presence of slips or fractures in the strata that make the extraction of the coal hazardous. The coal itself may be more friable and tender. Water or gas will often appear in increased quantities in proximity to a fault. The coal may thin out, the bottom rising or the roof bearing downward and almost squeezing out the coal. At other times, the coal seam is sheared off in a plane with little or no thinning out of the seam.

The dangers that attend the mining of coal, under these conditions, arise from the treacherous character of the roof and the presence of gas in increased quantity in places where open lights have been used and no warning has been given to employ safety lamps instead.

QUESTION—*What would be the horsepower on the air when 120,000 cu.ft. of air is passing per minute, under a water gage of 2.2 in.?*

ANSWER—A water gage of 2.2 in. corresponds to a pressure of $2.2 \times 5.2 = 11.44$ lb. per sq.ft. The horsepower on the air is then

$$H = (120{,}000 \times 11.44) \div 33{,}000 = 41.6 \text{ hp.}$$

QUESTION—*Would you recommend a fan or furnace for a new shaft mine 500 ft. deep? Give reasons for your recommendation.*

ANSWER—Assuming the mine is generating no gas, it will often be advisable to employ furnace ventilation, in the early development of the seam. The depth of a 500-ft. shaft will give a good air column and furnish ample ventilation in the mine, for a considerable time to come. However, in the later development of the mine, the safest plan will be to install a good ventilating fan and abolish the furnace. This is all the more important, because it is not known at what time the workings may generate gas; and furnace ventilation would be extremely dangerous in that event. Furnace ventilation can never be recommended if the seam generates gas, in *any* quantity, on being opened and its development started.

QUESTION—*What precautions are necessary in order to maintain a good current of air throughout the entire workings of a mine?*

ANSWER—First, equip the mine with a good ventilating fan capable of supplying the required quantity of air, against a specified water gage. Adopt a good plan of ventilation in which the main air current is divided one or more times, so as to provide a volume of air in each district of the mine that will comply with the mining law and keep the working places clear of gas. Keep all airways clear of obstructions and make all crosscuts and breakthroughs of equal cross-section with the airways. Erect the necessary doors, air bridges and stoppings to conduct the air forward and build brattices wherever required to make the air sweep the working face. All stoppings must be built in a substantial manner to prevent the leakage of air and special brattices must be provided to enable the current to sweep all falls and void places in the mine.

QUESTION—*What measures would you take to secure the best possible results from a fan, the capacity of which is limited and the demands on which approach dangerously close to that limit?*

ANSWER—Make every effort to reduce the mine resistance, by splitting the air current wherever its velocity will permit and good results are to be obtained; shorten the distance of air travel wherever practicable; clean up all airways, enlarge breakthroughs and remove every obstruction to the free passage of the air.

Says Herrin Acquittals Were Really Verdicts of Guilty Against Union

In a brief detailing the facts of the Herrin massacre and the two trials which failed to convict anyone for the twenty murders, counsel for the Bituminous Operators' Special Committee charged before the U. S. Coal Commission on May 17 "that the verdicts of acquittal for the individual defendants were in reality verdicts of guilty against the United Mine Workers of America."

The document charges, throughout, that the United Mine Workers, as an organization, planned and executed the crimes and by terrorism and the use of a special check-off tax approximating $900,000, together with community intimidation, prevented the guilty from being brought to justice. The entire affair, according to the brief, was in pursuance of "an avowed purpose of preventing any person not a member of the United Mine Workers of America from mining a ton of coal" during strike by the union and was designed to help starve the public into tolerating submission to the union's strike demands.

"What took place in Herrin was the logical and inevitable result of the establishment of this Mine Workers super-government in an American state. Such a result will inevitably follow its establishment in any other state just as soon as the aims and purposes of the super-government run afoul of the laws of that state."

Illinois Operators Oppose Severance Tax On Coal as Inequitable

The old, old battle is on in Illinois. Somebody is always trying to get the Legislature to levy a tax on coal at the mines to provide money for something. This year it is the state teachers' association asking that coal be taxed 8c. a ton. At a hearing in Chicago last week before the legislative committee the operators declared the tax would cut Illinois producers out of a good deal of business and would be unjust unless it applied uniformly over the whole country. The teachers' bill also would tax fluorspar $1 a ton and oil 5c. a barrel, and would be calculated to raise about $7,000,000 a year, which the teachers hope would be used to raise teachers' salaries and add to the income of state educational institutions.

A. J. Moorshead, president and general manager of the Madison Coal Corporation, said a severance tax would be inequitable as between Middle Western states' coal competition. Herman C. Perry, secretary of the Fifth and Ninth District Operators' Association estimated that a tax of even as much as 5c. a ton would reduce the Illinois output by 10,000,000 tons because very often a 5c. margin is enough to make or lose a sale. Thus, he argued, the tax would further reduce miners' working time and would work hardships in various places to counterbalance whatever benefits the school funds of the state would get. "You might as well tax bread as coal," he ended.

Dr. F. C. Honnold, of the Honnold Coal Bureau, of Chicago, said Illinois producers are already under a freight-rate and other handicaps in meeting competition from coals of surrounding states, including Kentucky, and that the addition of any further burden on Illinois coal would be hard to bear. He reminded the committee that the U. S. Coal Commission has asked that state legislatures defer action on coal legislation until the commission gets through its work. He revealed that Illinois operators already have spent $1,500,000 collecting data for the commission and hopes that nothing will happen to upset conditions in Illinois while the commission is making its investigation.

Says Autocratic Clique Runs Miners' Union

Most of the evils that afflict the anthracite industry could be eliminated "if the voice of the great majority of the rank and file of the miners can make itself felt through a more democratic management of the union," says a brief filed May 15 with the U. S. Coal Commission on behalf of the anthracite operators. The recommendation is made that "it should be unlawful to engage even in a general suspension, except after a two-thirds vote taken by secret ballot at the collieries under the supervision of the Department of Labor or some other public official."

The statement continues: "The United Mine Workers of America is not functioning fairly or democratically, either in respect to the public, the operators, or its own members. Union meetings usually are attended by only a small percentage of the total union membership, and this small attendance does not ordinarily include the most stable and steady miners, thus leaving the administration of union affairs with the more militant and noisy minority. The conduct of the meetings is such that freedom of expression and freedom to vote as one pleases are frequently denied those who desire to speak or vote against the less conservative clique or ring which manages the organization. . . .

"The result of these conditions, recognized and encouraged by the union constitution, is the autocratic conduct of union affairs by a small minority of the membership with a few union bosses."

Begin Hearings on Railroad Efficiency

The Interstate Commerce Commission began hearings May 16 on Docket 14556—Efficiency and economy of management of common carriers. A. H. Smith, president of the New York Central Lines, was the first to testify. His testimony was more or less of a historical nature, containing much statistics as to operation, net return on investment and other items.

Mr. Smith pointed out in his statement that in the decade 1910-1920 there was an increase of 157 per cent in the number of bituminous coal mines, while the increase in production was only 37 per cent.

He strongly advocated consolidation with the New York Central of the Ohio Central line, stating that it would enable the New York Central to compete better in service with other lines serving the smokeless coal fields of West Virginia, and also would help to stabilize the rate of return.

*Compiled by Ore & Coal Exchange, Cleveland, Ohio; H. M. Griggs, manager.

C. E. Maurer Assails Assigned-Car Practice Before Railway Fuel Convention

The fifteenth annual meeting of the International Railway Fuel Association in Cleveland this week had several addresses and papers of particular interest to coal men. George Cushing presented a paper on the "Classification of Coals" in which he argued, if he did not demonstrate, that coals cannot be classified. C. E. Maurer, president of the Glens Run Coal Co., told the railroaders comprising the audience what havoc assigned cars play with the soft-coal industry. The delegates were scheduled to a welcome from T. K. Maher, the veteran Cleveland coal operator, and R. F. Grant, of M. A. Hanna, extended the welcome of the city.

The following is an abstract of Mr. Maurer's address:

"It does not require a salesman to make a fuel contract with a railroad at the present time. It requires the service of a shrewd purchaser. The coal salesman does not approach the purchasing agent of a railway company to sell the product of his mines. He comes to buy railway equipment with which to operate his properties. His aim is not so much to sell his commodity at a profit but to barter his coal for open-top cars.

"I used the term barter. The system could be designated by a more vicious and better descriptive term were it not for the fact that this system has been quasi legalized by the Interstate Commerce Commission, one of the many super-government bodies created, that assume the authority not only to execute, make, suspend and construe federal and state statutes but the highest law of the land, the Constitution itself.

"Railroads were given certain rights not enjoyed by individuals. They can, when necessary, confiscate not only private real estate but private personal property. They can dissect the old home farm or destroy the city mansion, because private interests must be submerged to the public good. In return, however, they are supposed at least to be operated for the public benefit. They are legally forbidden to discriminate between shippers and passengers: to make no distinction between the strong and the weak: to give the same consideration to the corporations with thousands as those with millions: and finally to provide—not trade—equipment for all who might desire service.

"Today the railroads in the great coal-producing states, in so far as the coal itself is concerned are operated (1) for the benefit of those who are willing to barter their fuel for equipment; (2) for those who are sufficiently fortunate as to own their own private railway cars, and lastly, the public gets what is left of motive power and open-top equipment.

"This condition exists because the Interstate Commerce Commission has so ordered. The railroads are only carrying out its orders. If I should dare to criticize them, it would only be for the part they have taken in helping to bring about this situation. While rightly decrying government interference and charging many of their ills to their inability to conduct their own affairs, they have not hesitated to solicit that same interference, when some temporary advantage might be gained thereby.

"The great transportation systems, combined with an abundance of cheap fuel, are the foundations upon which our national wealth and progress are built. We owe our enviable position among the earth's great powers to these more than all else combined. Yet each has been made the vehicle upon which designing politicians have attempted to ride into popular esteem.

"The interests of both are mutual. The coal mines with their thousands of acres of unmined coal are the railroads' greatest asset. While time and conditions may vary, neither the location of the coal nor the mines can be changed and years hence in a constant stream will furnish an almost fixed annual revenue, not only to the railroads of the coal fields proper but to all their connections.

"At the same time the railroads are necessary to the coal. To a great extent the values of coal properties are measured by the transportation system to which they are tributary. Bankrupt railroads mean valueless coal mines. It would seem, under the circumstances, that instead of antagonizing each other, these great industries, upon which the public is so absolutely dependent, could find some common ground upon which they could unite that in the end the public might well be served. If they cannot reconcile their differences they only invite others much less qualified and ever willing to assume the task.

"The burden is primarily ours. We may for a time rely upon some temporary advantage either may have gained by doubtful legal decisions of commissions or otherwise. In the end, however, if the public suffers thereby, drastic means will be found to correct these evils.

"The present car-distribution rules for coal mines, if not revised by the Interstate Commerce Commission by and with the consent of the railroads, will be corrected by federal enactment, in no uncertain terms. The attempt was made in the Esch-Cummins Law, one paragraph of which, referring exclusively to distribution of cars at coal mines, provided that all cars placed at coal mines should be counted and charged against the mines receiving them.

"This part of the law, however, has been made a parody of by the Interstate Commerce Commission. A statute intended to prevent has been construed to license discrimination. I presume that the railroads are still counting and charging against certain coal mines the cars furnished to keep them in continuous operation since the enactment of the law. This duty at least was imposed upon them.

Counter Charges of Operators and Roads

"The coal operators of the country during the last year have correctly charged their inability to furnish coal to the public to lack of railroad equipment. The railroads in reply have submitted reports showing that the coal mines were supplied with from 50 to 70 per cent of their capacity requirements. I have no cause to doubt the correctness of these reports. At the same time I do know that they were not only misleading but absolutely incorrect in so far as the great coal-consuming public were concerned. Had anything like even a 50-per cent car supply been equally distributed to all the mines there would have been an abundance of coal for all.

"The distribution was not equal, however. The mines enjoying railroad fuel contracts were first supplied with equipment. Mines having contracts with or owned by individuals or corporations able to control their own cars were next supplied. And lastly the mines supplying the general public were given the balance, if any existed, of motive power and equipment with which they might operate.

"In so far as I know, this small balance was not only equally distributed but the cars were carefully counted and charged against the mines receiving them. As a result the public has paid the bill, and will continue to pay as long as the practice is continued.

"You can easily understand what this system means to the coal mines that can only operate from one to two days per week, while adjoining properties are operated continuously. Men cannot be held; their entire organization is destroyed; their output when able to operate is cut down and their costs doubled.

"The system works untold hardships on the employees of the mines on whom we are dependent for our fuel. Homes cannot exist nor can children be clothed when the heads of the families find employment but from one to two days per week. Do you wonder that they clamor for more wages? I have no hesitancy in saying that the miners fortunate enough to be employed at the mines enjoying these special privileges where work is constant are overpaid. I am just as certain, however, that no reduction in wages will come until the railroads find a way, through car distribution, to give them equal employment.

"The men upon whom the public is dependent for its heat

and power and every comfort are entitled to at least a fair livelihood. Any method of distribution of the equipment of the public-service corporations upon which they must rely that prevents their equally sharing therein will be paid for in full by those who must use the product of their toil.

"For the time being the railroads may operate their motive power to haul private equipment while their own lies idle on sidings. They may furnish cars to run certain mines six days per week and others less than two. They may provide the means whereby a few miners may have continuous employment while thousands are deprived of an opportunity to earn an honest livelihood. They may make one corporation's coal mines valuable and its neighbor's valueless. They may make cheap fuel for the favored few and expensive fuel for the countless balance, but the situation existing during the last year and at the present time cannot continue for long.

"It must be apparent to every man connected with the coal roads that not only the coal operators and the miners but the general public are being deprived of their legal and equitable share of transportation; that were there no legal obligation on their part to serve all equally, their sense of equity and justice for which they appeal for themselves and their interests, would lead them to give the same consideration to others dependent on them without waiting for a higher authority to intervene.

"A short time ago an able address was made by one of the leading Railroad Presidents before one of our Civic Bodies. He laid particular stress upon the fact that transportation companies should not be required to own sufficient rolling stock and equipment to carry the peak loads that only came periodically and be charged with this surplus when conditions were normal. No one can challenge his position. Had he only added 'but when the peak load is on, this equipment must be equally distributed without fear or favor or among classified necessary industries.' No more could have been desired.

"You are the men in a position to determine whether this present method is necessary to your department; to judge if it tends to improve the relationship between the great coal-producing interests and the coal-carrying railroads.

"There is a more equitable and a better way. The cost of the production of coal is known. All the mines on your lines of railroad are your natural assets. Nothing would better tend to increase the friendly relation between their owners and yourselves than to meet these men, not part but by all, either directly or through their representatives. Meet them with your executives and the heads of your managing departments. Discuss with them the value and cost of the fuel which they produce. Fix a price for your fuel that will render to them at least a reasonable return for the product of their mines, and then give every man an equal opportunity, providing he is so situated as not to inconvenience you, to furnish you his proportion of your fuel requirements based upon what his mines are able to produce.

"Give them to understand that in consideration of their furnishing you fuel at a reasonable price, all cars upon your lines will be distributed equally among all the mines, and you will have done more to establish a feeling of good will between these men and your railroads than anything that I can suggest. Not only among them, but you will have given all the employees at the mines along your lines of railroad an equal opportunity of earning a livelihood, and will have placed the public and all dependent upon you for coal in an equal position with yourselves."

SPEAKERS' BUREAU OF SPECIAL COMMITTEE ANNOUNCES COAL TALKS.—Addresses on the coal problem from the operators' standpoint have been booked by the speakers' bureau of the Bituminous Operators' Special Committee as follows: Kansas Bankers' Association, Hutchinson, May 24; Engineers' Club, Philadelphia, June 12; Michigan Bankers' Association, Detroit, June 18; National Association of Building Owners and Managers, Atlantic City, June 18. Invitations for speakers to represent the bituminous industry have been received from the following: Rotary Club of Cleveland; Mercator Club of Columbus; Kiwanis Club of Chicago; Exchange Club of Toledo; and the Jersey City Lodge, Foresters of America.

Forty-nine Companies Submit Bids on Coal for Government Fuel Yards

Forty-nine companies submitted bids to the U. S. Bureau of Mines for furnishing 200,000 tons, more or less, of bituminous coal to the Government Fuel Yards for the use of government departments during the period from June 1, 1923, to March 31, 1924. Offers were opened May 15 and details made public May 16. Of the total amount, 170,500 tons was on New River run-of-mine; 25,000 tons of Maryland, Pennsylvania or Northern West Virginia run-of-mine; 4,750 tons of New River nut and slack and 1,600 tons of gas coal. All quotations are on a gross ton basis, f.o.b. mines.

The following bids were submitted on Maryland, Pennsylvania and Northern West Virginia coal, run-of-mine: Rhodes Fuel Co., Uniontown, Pa., 5 cars daily, $2.75 per ton; Mostoller Coal Agency, Somerset, Pa., 20,000 tons at $2.25 per ton; Patton Coal Co., Fairmont, W. Va., 21,000 tons at $2.91 per ton; D. E. Williams & Co., Philadelphia, Pa., 40,000 tons at $3 per ton; Lynah & Read, Baltimore, 45,000 tons at $3.06 to Oct. 1, 1923, and $3.79, Oct. 1, 1923 to March 31, 1924; Madeira, Hill & Co., Philadelphia, Pa., 25,000 tons, $3.24 per ton to Oct. 1, 1923, and $3.64 per ton, Oct. 1, 1923, to March 31, 1924; D. E. Williams & Co., Philadelphia, 30,000 tons, $3.25 per ton; Lynah & Reed, Baltimore, 10,000 tons, $3.25 per ton; Lynah & Reed, Baltimore, 12,000 tons, $3.28 per ton to Oct. 1 1923 and $3.51, Oct. 1, 1923 to March 31, 1924; Matlack Coal & Iron Co., New York, N. Y., 50,000 tons, $3.34 per ton; Fidelity Coal Mining Co., Philadelphia, 21,000 tons, $3.34 per ton; Equitable Fuel Co., Baltimore, 5,000 tons, $3.35 per ton; Dexter & Carpenter, Inc., New York, 21,000 tons, $3.36 per ton, W. A. Merrill Sons & Co., Philadelphia, 21,000 tons, $3.36 per ton; Piedmont & Georges Creek Coal Co., Frostburg, Md., 75,000 tons, $3.36 per ton; Quemahoning Coal Co., Somerset, Pa., 60,000 tons, $3.36 per ton; Equitable Fuel Co., Baltimore, 50,000 tons, $3.42 per ton; Emmons Coal Mining Co., New York, 25,000 tons, $3.44 per ton; Maryland Coal & Coke Co., Philadelphia, 30,000 tons, $3.53 per ton; Davis Coal & Coke Co., Baltimore, 53.662 tons at $3.53 to Oct. 1, 1923, and 96,588 tons at $3.89 per ton, Oct. 1, 1923, to March 31, 1924; Ridge Hill Products Co., Philadelphia, 21,000 tons at $3.58 per ton; Equitable Fuel Co., Baltimore, Md., 5,000 tons, $3.63 per ton; Commercial Coal Mining Co., Philadelphia, 25,000 to 30,000 tons, $3.64 per ton; Brothers Valley Coal Co., New York, 50,000 tons, $3.64 per ton; D. E. Williams & Co., Philadelphia, 30,000 tons, $3.64 per ton; W. A. Marshall & Co., New York, 70,000 tons, $3.64 per ton; A. H. Powell & Co., Baltimore, 21,000 tons, $3.70 per ton; Price-Ryan Coal Co., Baltimore, 25,000 tons, $3.80 per ton; Quemahoning Coal Co., Somerset, Pa., 25,000 tons, $3.81 per ton; Pennsylvania Coal & Coke Corp., New York, 50,000 tons, $3.92 per ton; Dexter & Carpenter, Inc., New York, 21,000 tons, $4.06 per ton; Piedmont & Georges Creek Coal Co., Frostburg, Md., 60,000 tons, $4.20 per ton; Coleman & Company, Philadelphia, 10,000 tons, $4.20 per ton; W. H. Bradfort & Co., Inc., Philadelphia, 10,000 tons, $4.20 per ton; Eastern Fuel Co., Pittsburgh, Pa., 21,000 tons, $4.76 per ton; Equitable Fuel Co., Baltimore, 10,000 tons, $4.93 per ton; Consolidation Coal Co., Baltimore, Md., 4.000 tons, $7.30 along side dock.

The following bids were submitted on New River Coal, run-of-mine: Chesapeake & Potomac Fuel Co., Washington, D. C., 15,000 tons, $4.30 per ton; Equitable Fuel Co., Baltimore, 50,000 tons, $4.31 per ton; Fayette Smokeless Fuel Co., Mt. Hope, W. Va., 50,000 tons, $4.48 per ton; White Oak Coal Co., McDonald W. Va., 60,000 tons, $4.48 per ton; C. G. Blake Co., Cincinnati, Ohio, 5,000 tons monthly, price to be determined each month.

Nut and slack: White Oak Coal Co., McDonald, W. Va., 4,750 tons, $4.368 per ton; Maryland Coal & Coke Co., Philadelphia, 20,000 tons, $4.48 per ton.

Gas coal: Equitable Fuel Co., Baltimore, 1,600 tons, $2.74 per ton; Price-Ryan Coal Co., Baltimore, 1,600 tons, $2.97 per ton; Consolidation Coal Co., Baltimore, 1,600 tons, $3.08 per ton; Patton Coal Co., Fairmont, W. Va., 1,600 tons, $3.14 per ton; Matlack Coal & Iron Co., New York, 1,600 tons, $3.90 per ton.

National Chamber of Commerce Urges Consumers to Buy and Store Coal

Consumers are urged to purchase and store coal "as a matter of insurance, as a help in the transportation difficulty, and in order to assist in stabilizing the working time of the miners" by the Natural Resources Production Department of the Chamber of Commerce of the United States, of which W. DuB. Brookings, is manager, and C. T. Starr, chief of the Coal Bureau.

The bulletin issued by the development discusses the coal situation as of May 1 and declares that it is difficult to understand the apathy of the consumer in holding back his purchases in the light of past experience and in view of the present demand on transportation, including the car shortage, which shortage is expected to be accentuated by the usual heavy movement next autumn.

FRENCH AIMS IN THE RUHR would seem on the whole to be pretty good, if we are to judge from the way they have hit the mark.—*Manila Bulletin.*

Louisville & Nashville Lease of C. C. & O. Insures Outlet to Sea for Eastern Kentucky Coal

The Louisville & Nashville R.R. has obtained a lease for 999 years of the Carolina, Clinchfield & Ohio R.R., according to an announcement on May 16 by W. L. Mapother, president of the L. & N. As the C. C. & O. forms a belt through the coal fields of West Virginia, Tennessee and North Carolina, and links up with direct connections with tidewater at Charleston, the lease is expected to play an important part in the development of coal fields in eastern Kentucky. The Atlantic Coast Line, it is understood, will be a joint lessee with the L. & N. and will assist in the financing.

It is the intention of the L. & N. at once to spend many millions of dollars in connecting trackage in eastern Kentucky. This will link up all the lines of the L. & N. with those of the C. C. & O. It will give eastern Kentucky coal an outlet to the sea and will at once develop thousands of acres of coal land which, it had been thought, might be idle and unproductive for a quarter of a century.

Not only will the main system of the L. & N. be extended to line up with the new property but scores of small lines will be built, radiating out through the undeveloped coal lands of southeastern Kentucky and Tennessee.

A meeting of the directors of the L. & N. has been called for New York for May 23. After the contract is approved the consent of the L. & N. stockholders will be obtained and then the Interstate Commerce Commission must act. As the Carolina, Clinchfield & Ohio is not a competing system no objection is expected from that quarter.

"The acquisition of the C., C. & O. by the L. & N. is one of the greatest things that has ever happened in the development of eastern Kentucky," is the comment of R. C. Tway, of the Tway Coal Co., which has large properties on the L. & N. near Harlan, Ky. "It means that the hundreds of coal operators along the lines of the L. & N., for the first time, have an outlet to tidewater.

"At present we are shut out of all Atlantic seaboard business because of the impossibility of getting rates that will enable us to sell coal in competition with operators from other districts. When we have an outlet over the line of the C., C. & O. to Charleston, we can sell coal on the coastwise trade at all ports from New England and Florida. We all will share in the gigantic coal business of New York City, Philadelphia and all the other great cities of the East.

"One of our greatest handicaps for some years has been traffic congestion. Our coal has to leave Kentucky through the gateways of Cincinnati and Louisville. These outlets have been so choked with coal traffic that it has greatly handicapped production. Not only that, but the coal from the Harlan fields has had to go through a single track neck of the L. & N., leading northward to Corbin. That has been the cause of much loss of business though the inability to operate when cars could not move."

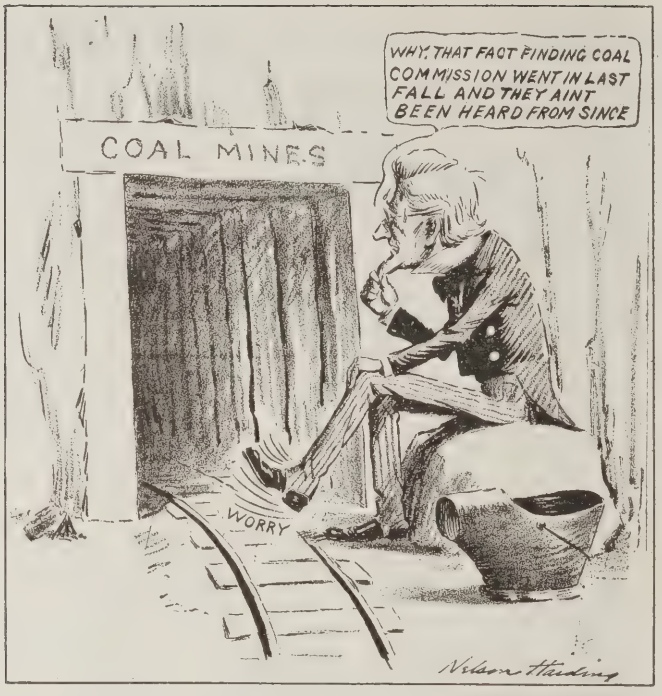
George Otis Smith Outlines Matters That Coal Commission Is Asked to Consider

At a meeting of the New York section of the Mining and Metallurgical Society held at the Harvard Club in New York City, May 16, George Otis Smith, now of the U. S. Coal Commission, was the principal speaker, W. Y. Westervelt presiding.

In the course of his remarks Mr. Smith stated that the commission had, at least, the merit of being a sort of rough cross-section of the American people. One of the propositions presented to the commission was to advocate that a curb be placed on the excessive development of coal areas which could be operated profitably only by the granting of excessively low freight rates considered on a per-ton mile basis. He said that the Pittsburgh coal operators complained that their shipments to the Great Lakes in normal years had declined from over 50 per cent of the total coal shipments to about half that, this loss being to eastern Kentucky and southern West Virginia, where a freight rate was given which was only 25c. per ton more than that from the Pittsburgh district, but where the distance to be traversed was 300 miles further. Putting the tonnage thus transferred to the area mentioned at 5,000,000 tons, or 100,000 railroad cars annually, the Pittsburgh operators have reason to contend that thus 1,500,000,000 ton-miles of freight every year were moved needlessly. This movement required perhaps 6,000 cars.

The diversion of coal for the Twin Cities from the Lake route to all-rail would involve a loss of a billion ton-miles per annum and is thought by some even more undesirable because it would put an end to that highly valuable storage of about 10,000,000 tons at Duluth-Superior alone, which has given the mines summer operation. Less shortage of cars would be experienced if distances of transportation were reduced, but in the past every effort seems to have been made to lengthen the haul and to favor the opening of new and unneeded mines.

Despite the excess of mines and of men and the shortage of railroad equipment, action is even now being taken toward building new coal branches where such development is least needed. The "dilution of coal-car service" by spreading them over too many mines and too many miles of railroad was a difficulty which had made the railroads unable to meet the real needs of the coal industry.



Another remedy proposed was to give mines an allotment of cars in proportion to the contracted coal. Mines having large contracts have found that, when business was briskest, the opening of new mines, which had preference because they were under development, reduced the number of cars available to mines having contracts. Thus one company which normally shipped 80 per cent of the coal going over a certain road received only 60 per cent of the cars when the market boomed, a host of small operations springing up to take advantage of the spot market. The companies that had made contracts with the coal companies were by failure to receive coal compelled to bargain for high-price spot fuel with those very operations which had made it impossible for them to get their contracts filled.

These references to transportation limitations were given as examples of the man-made handicaps under which the coal industry suffers and from which relief is sought.

Draft Program of Wholesalers' Convention

The tentative program for the convention of the American Wholesale Coal Association at Cincinnati calls for a meeting of the executive board of the association at the Hotel Gibson on the afternoon of June 11 to complete the preliminary plans. Wednesday morning, June 12, the official welcome will be extended by Julius Ratterman, chairman of the local committee, with a response from President Morton. Following this the reports of the secretary-treasurer, president and the traffic manager will be read. In the afternoon it is hoped to have Judge Alschuler, of Chicago, as the speaker, to be followed by a general discussion.

The annual dinner of the association will take place on the evening of June 12 with Charles L. Dearing, of Chicago, who is spoken of as the probable successor to the presidency, as the toastmaster. Edwin P. Morrow, Governor of Kentucky. will be the main figure on the program. Charles R. Moriarity, former president of the Cincinnati Coal Exchange, also will be on the program. On Thursday morning the election and installation of officers will take place Ladies who attend the convention will be taken on a motor sightseeing tour of the city on Wednesday afternoon; in the evening they will be welcomed at the annual dinner of the association and on Thursday morning they will be the guests of the official hostess of the Cincinnati Chamber of Commerce.

Engineers Announce Personnel and Plans of Committee to Probe Coal Storage

Personnel and plans of the committee which is to direct a national investigation of the storage of coal in co-operation with the U. S. Coal Commission, the Department of Commerce and the Bureau of Mines have been announced by the Federated American Engineering Societies. The committee members are H. Foster Bain, Director of the U. S. Bureau of Mines, Washington; David Moffat Myers, former Fuel Administrator, New York; Perley F. Walker, dean of engineering, University of Kansas; W. H. Hoyt, chief engineer of the Duluth, Missabe & Northern Ry., Duluth, Minn.; S. W. Parr, professor of applied chemistry, University of Illinois; Edgar S. Nethercut, secretary of the Western Society of Engineers, Chicago; Roy V. Wright, editor, New York. The chairman is W. L. Abbott, chief operating engineer of the Commonwealth Edison Co. of Chicago.

The investigation, the first of its kind to be undertaken in this country, will deal with the whole range of problems affecting the storage of coal. Factors involved, according to the Federation's statement, comprise cost, embracing the question of financing and providing means whereby coal in storage may be used as collateral; amounts of coal consumed at different periods, particularly by industries; provision by industrial organizations to aid the workers of the nation in securing coal supplies during the summer at a low cost; methods of handling and storing; effects of storage on the heating value of coal; transportation facilities; allaying labor unrest, and reducing the number of mines and miners.

"There are factors about which there is a lack of definite information," the Federation statement says. "They relate largely to the economics of coal storage, involving such problems as cost and the quantity that should be stored before winter begins. There also is the question of financing the storage of coal and providing means whereby coal in storage may be used as collateral for financing.

"No one has specific knowledge of the amount of coal consumed per month, per year. All that is known is the quantity produced by months, and roughly the amount consumed, but this does not give sufficient information whereby one may specifically determine the amount consumed per month. It, therefore, follows that it is not known whether more coal is consumed for industrial purposes during the summer than during the winter months. It is known, of course, that the domestic consumption is larger.

"The Federated American Engineering Societies have undertaken to make a definite study of the important factors in the whole question of the storage of coal, particularly to secure an adequate supply when and where needed. . . .

"In making this study, the Federated American Engineering Societies hope to bring to the attention of all concerned the fundamentals involved, the economic and social advantages to accrue to the public through a larger practice in the storage of coal."

Searles Tries to Shift to Operators Blame For Excess of Bituminous Miners

Ellis Searles attacks the statement of the bituminous coal operators with respect to who is responsible for the excess number of mines in the soft coal industry, in a "press release" dated May 15, 1923. He states in part that:

"Through the medium of amateurish statements issued to the press, the Bituminous Operators' Special Committee, a thoroughly non-union aggregation, has repeatedly made the charge that the United Mine Workers of America is responsible for the fact that there are 200,000 surplus miners in the coal industry. In their hectic demoralization these non-union operators seek to induce the public to believe that the miners' union reaches out and drags in men from anywhere and everywhere in order to increase its membership. Their statements on that subject are wholly untrue and should not be accepted or believed by the public. And in order that the commission may not be misled by any such mis-statements, purposely made, we desire respectively to call your attention to the real situation. We want the commission to have facts, not misrepresentations.

"The fact is that the coal operators themselves determine just how many members the United Mine Workers of America shall have; they determine just who shall become members of this union; they determine just who shall not become members of the union; they are responsible for the size and character of the membership.

"The union does not reach out and drag men into the industry and into its membership. The union does not have, nor does it attempt to exercise, the right to hire or discharge any man in or around any coal mine. That right belongs exclusively to the operator, and the union recognizes that right to the fullest degree.

"These coal operators continue to carry these 200,000 surplus men on their payrolls and refuse to turn them loose. There is not enough work to furnish steady employment for this vast number. The bituminous mines of the country are operating only approximately 40 to 50 per cent of full time. That's the reason there is so much idleness among coal miners. Yet each operator insists upon maintaining a 100 per cent working force of men at all times in order to be ready for capacity operation when the opportunity arises.

"Never was there a greater opportunity for a set of employers to perform a real service to the American public than that which now presents itself to the coal operators. If they will close down 4,000 of the unnecessary coal mines that are now open and operating spasmodically they will reduce the number of surplus miners proportionately and, thus *reduce the production cost of coal.* This, in turn, would mean *cheaper coal* to the consumer. That's what the consumer is interested in. The United Mine Workers of America cannot close down these mines, because it has no such right, power or authority. Nor can it, for the same reason, put 200,000 miners out of the industry. But the operators can do it if they will. We challenge them to make the start.

"The United Mine Workers of America has a membership of more than 500,000 men who are employed only a part of the time. The union, the operators, the industry, the public and the nation would be better off if there were 4,000 fewer coal mines and if there were 200,000 fewer miners with steady employment for all of them. But so long as the coal operators continue to hire more men; so long as they refuse to reduce their working force to a proper basis; so long as they insist upon keeping open these 4,000 useless mines; so long as they persist in their attempts to operate every possible mine, even at 40 per cent of full time, just so long must they assume responsibility for the demoralization that exists in the coal business."

Commerce Commission Hears Arguments for Cut in Rates on Coal from Kansas Field to Missouri River

The attention of the whole Middle West and Southwest coal industry centered largely on the rate hearing in Kansas City, Mo., which began May 17. There the battle of the Kansas and Oklahoma producers to get lower freight rates on Southwestern coal into their main market region, the Missouri Valley, or higher rates from Illinois into the same region, was fought with much verbosity. Southwestern producers contend that unreasonable rates are strangling them to death. Their opponents, the Illinois producers and the carriers with long hauls from Illinois to the valley markets, declare it is oil, not Illinois rates, that is doing the strangling, that present rates are fair, and that a revision downward would upset the rate fabric in various parts of the country. The Southwestern operators proposed a schedule of reductions on rates out of their own fields to valley points.

Submission of evidence to back up the complaint—I.C.C. docket No. 14,661 filed by the Southwestern Interstate Coal Operators' Association and the Oklahoma Coal Operators' Association—was made before J. P. McGrath, examiner for the Interstate Commerce Commission. The whole burden of the Southwest case, as put in mainly by C. E. Warner, traffic manager of the Southwestern association, and A. P. Budowsky, traffic manager of the Oklahoma association, was that present rates between all fields and the Missouri Valley are discriminatory in favor of Illinois.

Mr. Warner, the first witness, proposed a new scale of rates from the mines to the destination cities, designed, he explained, to bring about a more stable ratio between freight charges and distances hauled. As a basis for his schedule he suggested a charge of $2.49 a ton on lump from the Oklahoma-Arkansas mines to Kansas City, and $2.07 on slack. From the Pittsburg group he suggested a charge of $1 a ton less on each of the two grades, or $1.49 for lump and $1.07 for slack. For the sake of simplicity, dealing only with the two larger origin groups and the larger destination cities, Mr. Warner's suggested changes may be tabulated as follows:

TO KANSAS CITY

From Oklahoma-Arkansas: Rates	Lump	Slack
Present	$3.28	$2.21
Proposed	2.49	2.07
Reduction	.79	.24
From Pittsburg:		
Present	$1.70	$1.34
Proposed	1.49	1.07
Reduction	.21	.27

TO ATCHISON, ST. JOSEPH AND LEAVENWORTH

From Oklahoma-Arkansas: Rates	Lump	Slack
Present	$3.52	$3.04
Proposed	2.74	2.32
Reduction	.78	.72
From Pittsburg:		
Present	$1.82	$1.70
Proposed	1.54	1.32
Reduction	.28	.38

TO OMAHA AND COUNCIL BLUFFS

From Oklahoma-Arkansas: Rates	Lump	Slack
Present	$3.89	$3.52
Proposed	3.49	3.07
Reduction	.40	.45
From Pittsburg:		
Present	$2.67	$2.31
Proposed	2.49	2.07
Reduction	.18	.24

TO SIOUX CITY

From Oklahoma-Arkansas: Rates	Lump	Slack
Present	$5.22	$4.50
Proposed	3.99	3.57
Reduction	1.23	.93
From Pittsburg:		
Present	$3.77	$3.04
Proposed	2.99	2.57
Reduction	.78	.47

From the table it may be seen that Mr. Warner's idea is to make the charge on both grades from all origin groups to Leavenworth, Atchison and St. Joseph 25c. higher than to Kansas City; Omaha and Council Bluffs, $1 higher than to Kansas City; and to Sioux City, $1.50 higher than to Kansas City. Such a schedule, he maintained, would equalize haulage charges in relation to distances hauled and do away with present apparently discriminatory charges from origin groups to destination groups. Also, he testified, it would give the mines of the Southwest a more even break with the mines of Illinois in competition for the northern Missouri River market. No charge of discrimination in the market for Kansas City and adjacent territory, as between Illinois and Southwestern mines, was pressed.

The present rates between southern Illinois mines and Omaha are $3.71 for lump and $3.34 for slack, Mr. Warner said, while from the Belleville and Springfield districts they are $3.28 for lump and $2.92 for slack. Rates from Springfield to Kansas City on the Chicago & Alton and on the Wabash, both of which have direct lines between the two points, are $2.49 for lump, $2.37 for commercial lump and $2.07 for slack, Mr. Warner said.

Mr. Warner was followed by Mr. Rudowsky, whose testimony was an elaboration of that which had preceded. Mr. Rudowsky described conditions in the coal fields of the Southwest, where mines are operating only one or two days a week as a result of no market. Lower freight rates, he declared, would strengthen the market and give the mines more operating time.

A. M. Corp, Topeka, statistician for the Kansas Public Utilities Commission, testified that traffic density on railroads of the territory through which coal from the Southwestern mines must pass to the Missouri River markets differed little from that through which Illinois coal must pass to the same market. Cross examination of Mr. Corp attempted to show that he used different standards of comparison in his figures, using gross tonnage measurements in some cases where net tonnage should apply.

H. L. Bennett, Oklahoma City, rate expert for the Oklahoma corporation commission, made similar comparisons of traffic density between the Oklahoma and Illinois mines and the Missouri River. Both the states of Kansas and Oklahoma are interveners for the complaints.

John L. Brown, representing the coal dealers of Sioux City, Iowa, declared many industries in Sioux City have been forced to burn oil instead of coal because of prevailing high railroad rates. C. H. Markham, of the Midland Coal Co., of Kansas City, had testified to the same effect concerning the competition between oil and coal in Kansas City.

Clyde M. Reed, chairman of the Kansas Public Utilities Commission representing not only the state but also mining communities and the miners' organization, was the final witness for the complaint. His testimony was based principally on his official observations while a member of the Kansas Industrial Court, and later as a member of the Utilities Commission. He said between 8,000 and 10,000 men in mining regions are now out of work.

R. T. Willette, transportation commissioner for the Atchison Chamber of Commerce; C. E. Childe, transportation commissioner for the Omaha Chamber of Commerce, and W. H. Fitzpatrick, traffic commissioner of the St. Joseph Chamber of Commerce, testified concerning the effect of present rates on their cities, and all requested rates even lower than those suggested by Mr. Warner.

H. S. Mitchell, manager of the Coal Credit and Correct Weight Bureau of the Kansas City Chamber of Commerce; William Bartrim, of the Alpine Ice & Fuel Co., Kansas City, and Charles L. Dooley, traffic manager of Peet Bros. Mfg. Co., Kansas City, were other witnesses for the complaint.

The defendants and railroad interveners in opposition to the complaint were of three distinct groups—the Southwestern origin lines. whose principal coal traffic is from the mines of the Southwest; the lines whose principal coal business in the Missouri Valley is from Illinois mines to valley markets, and those which serve both the Southwest and Illinois. Of the first group, the Missouri Pacific, the Frisco, the Kansas City Southern and the Missouri, Kansas & Texas were selected by the Southwestern Freight Bureau to conduct the defense. These four roads have attempted

to reduce rates in the past, but their reductions have been overruled by the Interstate Commerce Commission.

C. C. P. Rausch, of the Missouri Pacific; Bruce A. Rodgers of the Kansas City Southern, and H. E. Morris, of the Frisco, testified that coal shipments over their lines have been dwindling in recent years. They denied that their present rates are too high, but insisted that rates from Illinois to the Missouri River are too low.

The Wabash offered the first spirited testimony for the defense. The Wabash has a direct line from Illinois to Missouri River territory, but it also carries transfer coal from the Southwest to northern Missouri Valley cities. T. R. Farrell, of St. Louis, assistant general freight agent of the Wabash, defended present rates from Illinois, and declared unequivocally his road's intention to combat reductions from the Southwest.
